Soissons is generally believed to occupy the site of the oppidum of Galha Belgica called *Noviodunum* by Caesar, but some writers identify this place with Novon, Noyant, or Nonvion. One thing is clear, that this oppidum was the capital of the Suessones, who occupied twelve towns and whose king, Divitiacus, one of the most powerful in Gaul, had extended his authority even beyond the sea among the Britons. In 58 B.C. Galba, king of the Suessones, separated from the confederation of the Belgians and submitted to the Romans. At the beginning of the empire Noviodunum took the name of *Augusta Suessionum*, and afterwards that of *Suessona*, and became the second capital of Galha Belgica, of which Rheims was the metropolis. The town was before long surrounded with a regular wall and defended by a citadel, and it became the starting point of several military roads (to Rheims, Châtillon Thierry, Meaux, Paris, Amiens, and St Quentin). Christianity was introduced by St Crispin and St Crispinian, men of noble birth, who, however, earned their livelihood by shoemaking, and thus became patrons of that craft. After their martyrdom in 297 their work was continued by St Simitius, the first bishop of Soissons. After the barbarians had crossed the Rhine and the Menno Soissons became the metropolis of the Roman possessions in the north of Gaul, and on the desert of Syagrius by Clovis the Franks seized the town. It was at Soissons that Clovis married Clotilde, and, though he afterwards settled at Paris, Soissons was the capital of his eldest son Lothaire, and afterwards of Chilperic I, king of Neustria. It was not till the time of Chilperic's son, Lothair II, that the kingdom of Soissons was incorporated with that of Paris. In 752 Pippin the Short was at Soissons proclaimed king by an assembly of lords and bishops, and he was there crowned by the papal legate St Boniface before being crowned at Saint Denis by the pope himself. Louis the Pious did penance there after being deposed by the assembly at Compiègne. Under Charles the Fat (886) the Normans failed in an attempt against the town, but laid waste St Médard and the neighbourhood. In 923 Charles the Simple was defeated outside the walls by the supporters of Rudolph of Burgundy, and Hugh the Great besieged and partly burned the town in 948. Under the first Capets Soissons was held by hereditary counts, frequently at war with the king or the citizens. Thus the latter bought in 1131 a communal charter from Louis VI and their bishop. In 1155, at an assembly of prelates and barons held at Soissons, Louis VII issued a famous decree forbidding all private wars for a space of ten years, and in 1325 Charles the Fair replaced the mayor of Soissons by a royal provost dependent on the bailiwick of Vermandois, the inhabitants retaining only the right of electing four *chevins*. Louis of Châtillon, count of Soissons, was killed at Crécy, and his son, a hostage for King John in England, sold his countship to Enguerrand de Coucy to obtain money for his ransom in 1367. Finally the last count of Soissons, sprung from a branch of the house of Bourbon, rebelled against Louis XIII and defeated the royal troops at La Marfée in 1611, but perished in the battle. The town had to suffer severely during the war of the Hundred Years in 1414, when it was held by the Burgundians, it was captured and sacked by the Armagnacs under the dauphin, and this same fate again befell it six times within twenty years. The treaty of Arras (1435) brought it again under the royal authority. It was sacked by Charles V in 1544 and in 1565 by the Huguenots, who

laid the churches in ruins and, supported by the prince of Condé, count of Soissons, kept possession of the town for six months. During the League Soissons eagerly joined the Catholic party. Mayenne made the town his principal residence, and he died there in 1611. A European congress was held there in 1728. In 1814 Soissons was captured and recaptured by the allies and the French. In 1815, after Waterloo, it was a rallying point for the vanquished, and it was not occupied by the Prussians till the 13th of August. In 1870 it capitulated to the Germans after a bombardment of three days.

SOKOTO, an important Fulah kingdom or empire in Central Soudan, comprising what are frequently called the Hausa states. Its boundaries (see vol. 1, pl. II.) are irregularly marked off by the plateau lands of Air or Asben on the north, the kindred Fulah state of Gandu on the west, while the river Benue practically forms its southern limit as far as the meridian of 10° E., beyond this it runs south into the Congo basin. On the east lies the kingdom of Bornu. From north-west to south-east Sokoto has a length little short of 900 English miles and its average breadth is about 280. The whole area has been roughly computed to be equal to that of Spain (about 195,000 square miles), and to have a population of from ten to twelve millions. The country may be described as a great undulating plain, rarely exceeding 1000 feet in height, with the exception of the province of Bauchi in the centre, which runs into a highland region with heights of 3000 feet, and the still more imposing masses of Adamawa in the south, which are said to attain an altitude of 10,000 feet in Mount Alantika. In other respects Sokoto presents more varied features, chiefly determined by the amount of rainfall, though the varying fertility of the soil is a not unimportant factor. In the southern parts, where there are almost perpetual rains, large streams and rivers are numerous, —the feeders of the Benue, the great eastern (left-hand) tributary of the Niger. Here grow the virgin forests with giant growths and exuberant foliage, with creepers, with bananas and plantains, palm-oil trees and yams. In the more temperate — because more elevated — districts of the middle area, with a smaller rainfall, the vegetation is less luxuriant, and such fruits as the date, lime, and pomegranate are cultivated. In the northern parts the climate is still more arid, and the country is burned up for the greater part of the year. This is the region of acacias and mimosas, of baobabs, of the branching dum palm and the curiously bulged deléb. Here are no forests nor rank grass, while the exigencies of a dense population have caused the clearing away of the bush except on the most barren spots, where it supplies the necessary fuel for domestic purposes. In this northern district there are no streams except in the wet season, and the wants of the people are supplied by fountains in the more favoured places, and by wells — frequently very deep — in those not so advantageously situated. Lying within the tropics, Sokoto is subject to excessive heat, — damp and steamy in the south, dry and furnace-like in the north, where it suffers from the hot winds from the Sahara. In Adamawa the rainy season — or, to be more correct, the season of excessive rains — commences in April and lasts till October or later, while in Guber in the north the rains commence in June and seldom last more than three months, during which the country becomes transformed from a repellent desert into a well-cultivated nursery garden.

For Central Africa Sokoto may be described as fairly healthy, though, as may be expected from a conjunction of excessive heat with excessive rain, fevers are not uncommon in the southern parts, while ophthalmia is prevalent in the north, especially among the poorer classes, who are compelled to expose themselves to the blinding dust from the deserts and the excessive glare of the sun reflected from the burning sands.

The natural productions of Sokoto are such as are more or less common throughout the whole of the Soudan (q.v.). Among cereals rice and wheat are cultivated in many parts, though the staple productions are kañne corn, millet, and maize. Sweet potatoes,

ground nuts, yams, onions, and other vegetables are largely grown. Of fruits dates, pomegranates, citrons, and bananas abound in more restricted areas. The Shea butter tree supplies an excellent oil for lamps, and also for cooking, though it is only used by the poorer classes. The palm oil tree is only found in the damp basin of the Benue. The most important vegetable products are cotton and indigo, which are universally grown. The cotton is manufactured into cloth, being used by the native population as well as largely exported to neighbouring countries. In some parts a species of silk found in the forests is largely used, and the people of Yakoba in Bauchi are said to rear the silkworm. Of mineral products there seem to be few, though it is known that both silver and lead occur in the Benue area. Iron is even more diffused and of excellent quality.

The inhabitants of this extensive region, held together by a conquering race and not by any natural tie into one common kingdom, are of diverse tribes and affinities. They, however, may be roughly divided into three groups. (1) First come the pure Negro races of Adamawa, of which the chief tribe is the Batta. (2) The Hausa form the mass of the population except in Adamawa. They are pre-eminent among Negroes for their physical appearance and intellectual abilities. They are wonderfully skilled in various arts and industries and noted for their commercial genius and enterprise. Mohammedanism is their religion, and indeed in all respects they are well advanced on the road to civilization. They are very fond of voluminous clothes. (3) The Fulahs are a Hamitic race, who from being simple herdsmen in the beginning of the 19th century have become the rulers and masters over a hundred alien races between the Atlantic and Lake Tchad. They have not the commercial or industrial skill of the Hausa, but in other respects have reached a higher level. They are of slender build and are distinguished by their light copper colour. The inhabitants of Sokoto live mostly in large towns, many of which contain from 10,000 to 20,000 inhabitants. These towns are all protected by strong mud walls and outer dry moats. Their interior is divided into a series of compounds, each entered through a flat roofed audience chamber. Inside are the beehive shaped huts of the household. The gateways are also strongly fortified. The ruler over Sokoto is a Fulah sultan, whose power is absolute, though tempered by a species of feudal system. The governors of some of the larger provinces, though owing allegiance to the sovereign, are mostly hereditary, and beyond sending a yearly tribute are practically independent. The tie indeed is more religious than anything else. The great weakness of the empire is its want of coherence and the absence of a strong central Government. Yet, though always appearing to be on the point of falling to pieces, it contrives to keep together. The condition in which Barth found it in 1855 was practically the same as when the present writer visited it in 1895.

The chief provinces of Sokoto are Zamphoro, Zaria, Katsina, Banchi, Kano, and Adamawa. The most important towns are — Sokoto, the acknowledged capital of the empire, famed chiefly for its leather work and straw hats (it divides with Wurnu the distinction of being the residence of the sultan, Clapperton died here in 1837), Wurnu, about 18 miles farther east, the present (1887) headquarters of the court, Kano, the great commercial emporium of Central Soudan, and Yakoba, chiefly noted for its large size, — said to contain 150,000 inhabitants.

The history of Sokoto may be said to have commenced with the 19th century. Previous to that date little is known further than that the country was divided among a number of small chiefs, a prey to the powerful kings of Bornu, Kebbi, and Songhai (Songhai). In 1802 the Fulahs, then little regarded and semi-servile in position, were scattered all over the country, apparently without any national tie to unite them to common action. At last, however, an imam — one Othman dan Fodio — appeared, who with the watchword of Islam gave a new life to his tribesmen and in an incredibly short time transformed them from peaceable nomads into soldiers of the Crescent, and after a few initial reverses swept like a whirlwind over an enormous area, establishing himself as ruler and Mohammedanism as the religion of the whole of Central Soudan. At his death the parts now known as Sokoto fell to the share of his son Bello, and in the family of Othman the reins of government have since remained, though the descent is not as a rule from father to son, but either to a brother or a brother's son. The latest phase in the history is the proclaiming of a protectorate over a part of Sokoto on the Benue by the British Government, and the handing over of the administration of the Niger region to the Royal Niger Company. To this company the sultan has conceded all his rights on the Benue and a monopoly of trade throughout his dominions, thus making them practically masters of all foreign intercourse.

The most important sources of information regarding Sokoto are — Clapperton's *Journeys in the early part of the 19th century*. Barth's *Travels in Central Africa between 1849 and 1855*, — a perfect mine of information, and Rohlf's *Reise durch Nordafrika vom Mittelmeer nach dem Tschad-See* in 1866-67. Among later and minor travellers have been Flegel, who visited Sokoto in 1880 and Thomson who conducted a commercial and political mission to the court of the sultan in 1893.

SOLAN GOOSE See GANNET

SOLARIO, ANTONIO (c. 1382–1455), a painter of leading importance in the Neapolitan school, is commonly called Lo Zingaro, or The Gipsy. His father is said to have been a travelling smith. To all appearance Antonio was born at Civita in the Abruzzi, although it is true that one of his pictures is signed "Antonio de Solario Venetus," which may possibly be accounted for on the ground that the signature is not genuine. Solario is said to have gone through a love adventure similar to that of the Flemish painter, Quintin Massys. He was at first a smith, and did a job of work in the house of the prime Neapolitan painter Colantonio del Fiore, he fell in love with Colantonio's daughter, and she with him, and the father, to save him off, said if he would come back in ten years an accomplished painter the young lady should be his. Solario studied the art, returned in nine years, and claimed and obtained his bride. The fact is that Colantonio del Fiore is one of those painters who never existed, consequently his daughter never existed, and the whole story, as relating to these particular personages, must be untrue. Whether it has any truth, in relation to some unidentified painter and his daughter, is a separate question which we cannot decide. Solario made an extensive round of study,—first with Lippo Dalmasio in Bologna, and afterwards in Venice, Ferrara, Florence, and Rome. On returning to Naples he rapidly took the first place in his art. His principal performance is in the court of the monastery of S. Severino—twenty large frescos illustrating the life of St. Benedict, now greatly decayed, they present a vast variety of figures and details, with dexterous modelling and colouring. Sometimes, however, Lo Zingaro's colour is crude, and he generally shows weakness of draughtsmanship in hands and feet. His tendency is that of a naturalist,—the heads life-like and individual, and the landscape backgrounds better invented and cared for than in any contemporary. In the Study gallery of Naples are three pictures attributed to this master, the most remarkable one being a Madonna and Child Enthroned with Saints. The heads here are reputed to be mostly portraits. Solario initiated a mode of art new in Naples, and the works painted between his time and that of Tesauro are locally termed "Zingareschi." He had many scholars, but not of pre-eminent standing—Nicola Vito, Simone Papa, Angiolillo Roccadirame, Pietro and Ippolito dal Donzello. It has often been said that Solario painted in oil, but of this there is no evidence.

SOLDER is a metallic alloy or metal employed for cementing or binding together two metallic surfaces. The solder is applied to the surfaces to be united in a molten state, and it is therefore generally either a more fusible body than the metal to be acted on or it is presented in a more fusible condition. The process of autogenous soldering consists in uniting the individual metallic edges themselves by melting and fusing them in the heat of the oxyhydrogen blowpipe or by means of an ignited blast of mixed coal gas and air. Autogenous soldering is extensively used in connexion with large plumber work. Ordinary solders are divided into hard and soft classes, the hard comprising such as require a red heat for their melting. The soft solders used by plumbers and tinsmiths consist of variable mixtures of lead and tin, and for pewterers' use bismuth is added to these. The hardest brazing solder has equal parts of copper and zinc, and for softer qualities increased amounts of zinc with tin and sometimes antimony are employed. For fine jewellery alloys of gold, silver, and copper are used, silver solder is employed for inferior qualities, and even common soft solder finds extensive employment in the jewellery trade. Silver is the proper solder for German silver manufactures

also, and gold is the medium for joining the edges of platinum vessels. In soldering, the metallic edges to be united must be free from oxidation and dirt, and to keep them unoxidized during the operation several fluxes are used, such as borax in brass soldering, rosin and solution of zinc chloride for tin-plate, zinc chloride for zinc, rosin and tallow for lead and tin, and olive oil in pewter work. Special machinery has been devised for the soldering of the tinned cases now so extensively employed in the preserved food trade. In common soft soldering the solder is melted and applied to the joint by a heated iron or copper soldering bolt, but solders are also applied by being melted on in the open fire, or in the muffle furnace, by immersing the joint in a bath of molten solder, or by pouring the molten material on the joint. In dealing with hard solders the heat of the blowpipe flame is used.

SOLE Soles are a group of Flat-Fishes (*Pleuronectes*), which is represented by numerous species in all suitable localities within the temperate and tropical zones, they become, however, scarce in the southern parts of the southern temperate zone, and are absent altogether in some districts—for instance, on the coasts of southern Australia. Many of the species enter fresh water freely, and some have become thoroughly acclimatized in it. Soles are a highly specialized type of flat-fish, their mouth is very narrow, twisted round to the blind side, and small teeth are developed on that side only. As they always lie on swim on one side, the pectoral fins have ceased to have a function, and consequently these organs are reduced in size, and in many of the species are mere rudiments or are lost entirely. The eyes are small, invariably on the right side of the fish, the upper occupying a position more or less in advance of the lower. Soles are littoral fishes, inhabiting sandy bottoms, shifting with the season from shallow into somewhat deeper water. Like all flat-fishes they are carnivorous, but feed on small animals only, none attain to a large size, scarcely exceeding that of 2 feet. Of the forty species known of the genus *Solea*, four are found on the British coast, the one most generally known and commercially most important is the Common Sole (*Solea solea*), it seems to occur in greater or less abundance on all flat coasts of Europe, but its numbers have been considerably thinned within the last quarter of a century, at least on the British coasts, doubtless in consequence of the introduction of the trawl. At any rate, that over fishing is the cause of the decrease of this valuable table fish is amply proved by the fact that simultaneously with the quantity the average weight of the fish has been diminished, soles of 12 inches in length and of 8 ounces in weight being now in many localities the largest that can be obtained. At present young specimens form the majority of the soles in the market, and are sold under the names of "ships" or "tongues." During the breeding season, which falls in the months from February to April, soles lose much of their flavour. It is a singular fact that male soles seem to be almost unknown, and some ichthyologists account for it by supposing that the males remain much smaller than the females, and are overlooked in consequence. The Lemon Sole (*Solea amantia*) is much less esteemed than the common sole, and more rarely seen in the market, probably because it is locally distributed in deeper water. It is of a yellow colour, marbled with brown and irregularly spotted with black, the pectoral fin is ornamented with an ovate black spot on its inner half. Even when this bright coloration has disappeared in the fish after death, it may always be distinguished from the common sole by its large dilated nasal opening on the blind side, which is surrounded by a broad fringe. The Variegated Sole (*Solea variegata*) is at times taken in considerable numbers.

on the south coast by means of the trawl, and esteemed as a table fish. It differs from the two preceding species by the rudimentary condition of the pectoral fins, that of the blind side being minute. The colour is brown, darker bands cross the body, and are darkest on the dorsal and anal fins, where they appear as a row of about six large spots. It does not appear to grow to the same size as the common sole. The fourth British species, *Solea minuta*, is still smaller, not much exceeding 5 inches in length, it is therefore not of commercial importance, although it may be caught at times in the trawl in large numbers. As in the preceding species, the pectoral on the blind side is minute, but that of the right side is large enough to show a distinct black spot. The colour of the body is brownish or greyish, with small black spots, and every sixth or seventh ray of the dorsal and anal fins is black.

Flat fishes resembling soles abound on the shores of the Indian Ocean beside the true soles, but they have the eyes on the left side of the head and lack pectoral fins altogether. They have been referred, therefore, to distinct genera, such as *Plagusia* and *Cynoglossus*.

SOLEURE, or **SOLOTHURN**, is one of the cantons of Switzerland, ranking as tenth in the Confederation, and taking its name from its chief town. As it consists simply of the territories now by the city, its irregular shape is easily accounted for. It takes in most of the valley of the Aar between the towns of Soleure and Olten, but stretches across the eastern Jura to Dornach not far from Basel, while to the south it tends in the direction of Bern. The total area is 305.9 square miles, of which all but 25.4 square miles is classed as "productive," 103.3 square miles of this being covered by forests. In other words, 91.7 per cent. is fertile. The highest point in the canton is the Hasenmatte (4754 feet), in the range behind the town of Solenre, in which too is the Weissenstein (4213 feet), so well known as a great centre for the air and whey cure, as also for its fine view. In 1880 the population of the canton was 80,424 (an increase of 5754 on the census of 1870), the women outnumbering the men by 1704. Of these no fewer than 79,514 are German speaking.

Soleure now includes 63,037 Roman Catholics to 17,114 Protestants, but in the ten years 1870-1880 the latter increased by 4666, the former only by 965. Ecclesiastically the districts now forming part of the canton belonged till 1814 to the dioceses of Lausanne, Basel, and Constance, but since the complete reorganization of 1828 it is part of the diocese of Basel, and the bishop of Basel lives in the city of Soleure.

The only places of any size in the canton are its capital, Soleure (7668 inhabitants), which possesses the finest armoury in Switzerland, and Olten (3979). It is counted as one of the most fertile and productive cantons in the Confederation, and exports iron, wood, marl, marble, glass, &c. In educational matters it takes a high place, and its two chief towns are connected by a railway, Olten being one of the principal railway junctions in Switzerland, and the meeting place of the St Gotthard railway with the main lines branching off to the north, east, and west.

An old rhyme claims for the town of Soleure the fame of being the oldest place in "Gallia" save Treves. Certainly its name "*Salodurum*" is found in Roman inscriptions (the termination possibly pointing to a Celtic origin), and its position as commanding the approach to the Rhine from the south west has led to its being more than once strongly fortified. Situated just on the borders of Alamannia and Burgundy, it seems to have inclined to the latter allegiance, and it was at Soleure that in 1038 the Burgundian nobles made their final submission to the emperor Conrad II. The mediæval town grew up round the house of secular canons founded in honour of St Ursus and St Victor (two of the Thetan legion who are said to have been martyred here in the 3d century) by Queen Bertha, either the mother of Charlemagne and wife of Pippin (8th century) or the more famous wife of Rudolph II., King of Burgundy (10th century), and was naturally in the

diocese of Lausanne. The prior and canons had many rights over the town, but criminal jurisdiction and the "advocacy" of the house remained with the kings of Burgundy, passed to the Zaring dynasty, and on its extinction in 1218 reverted to the emperor. The city thus became a free imperial city, and in 1272 shook off the jurisdiction of the canons and took them under its protection. In 1295 we find it allied with Bern, and this connexion is the key to its later history. It helped Bern in 1295 in the great fight against the nobles at the Dornbühl, and again at Langnau in 1309 against the jealous Burgundian nobles. It was helped in 1322 by Duke Leopold of Austria (the defeated of Morgarten) during the struggle for the empire, but he was compelled to withdraw. In the 14th century the government of the town fell into the hands of the guilds, which practically filled all the public offices. Through Bern (which became a member in 1373) Soleure was drawn into association with the Swiss Confederation. An attempt to secede from it in 1382, made by the decreasing Kyburg branch of the Hapsburgs, was foiled, and resulted in the admittance of Soleure in 1384 into the Swabian League and in its sharing in the 50-year war. Though Soleure took no part in that battle, she is included in the Sempach ordinance of 1386 and in the great treaty of 1394 by which the Hapsburgs renounced their claims to all territories within the Confederation. In 1411 she again sought to be admitted into the Confederation, a petition only granted to her in 1451 at the diet of Stans, after she had taken part in the Argaw, Italian, Toggenburg and Burgundian wars. It was also in the 15th century that by purchase or conquest she took as part of the main part of the territories forming the present canton. In 1522 the majority of the "communes" went over to the Reformation, and men were sent to fight on Zwingli's side at Kappel (1531) but in 1533 the old faith regained its sway, and in 1541 Soleure was a member of the Golden or Portmouche League. Though the city ruled the surrounding districts the peasants on both sides and hence their revolt in 1653 was not so violent as in other places. Soleure was the usual rendezvous of the French and no doubt this helped on the formation of a patrie. In 1651 no French cities were a hostile and it was not only to enter five ruined families distributed over the eleven guilds. Soleure was abolished by Soleure in 1788. The old system of the city ruling over eleven burghs came to an end in March 1798, when Soleure opened its gates to the French army. She is one of the six "directorial" cantons under the 1801 constitution. In 1814 the old aristocratic government was set up again but this was finally broken down in 1829, Soleure in 1842 joining the League of the Seven to guarantee the maintenance of the new cantonal constitutions. Though distinctly a Roman Catholic canton she did not join the "Sonderbund," and voted in favour of the federal constitutions of 1848 and 1874. Since 1879 she has revised her constitution in 1840, 1870, 1876, and 1877, besides three partial revisions of 1867, 1869, and 1881. The present constitution may be described as an ultramontane democracy, the priests having very great influence. The "kantonsrath" or legislative assembly is elected by all citizens over twenty years of age. In the proportion of one member to 800 inhabitants. This assembly selects the "Politiker" or executive, consisting of five members. In both cases the period of office is five years, though on the demand of 4000 citizens a popular vote must be taken as to whether the existing members shall continue to sit or not. In the canton the obligatory referendum and the initiative are legal. By the former all laws passed by the assembly, and all financial resolutions involving the expenditure of 100,000 francs or of an annual sum of 20,000 francs, must be approved by a popular vote. By the latter 2000 citizens can compel the assembly to consider any proposal for making a new law or for amending an old one. Further, the demand of the majority of the assembly or of 3000 citizens is sufficient to necessitate a popular vote as to the advisability of revising the constitution, the revised draft itself requiring a further popular vote.

SOLI, an ancient town of Asia Minor, on the coast of Cilicia, between the rivers Lamus and Pyramus, from each of which it is about 62 miles distant. Colonists from Argos in Greece and Lindus in Rhodes are described as the founders of the town, which is first mentioned in history at the time of the expedition of the younger Cyrus. In the days of Alexander the Great it was so wealthy that that conqueror exacted from its inhabitants a fine of 200 talents. In the war between Mithradates and the Romans Soli was destroyed by Tigranes, but it was subsequently rebuilt by Pompey, who settled there many of the pirates whom he had captured, and called the town after himself, Pompeiopolis. Soli was the birthplace of Chrysippus the Stoic and of the poets Philemon and Aratus. The bad Greek spoken there gave rise to the

term *σολοιτισμός*, "solecism," which has found its way into all the modern languages of Europe. Extensive ruins still mark the site of the town, the place is now called Mezethu.

SOLICITOR See **ATTORNEY**. It should be noticed that by the Supreme Court of Judicature Act, 1873, § 87, all persons admitted as solicitors, attorneys, or proctors of any English court, the jurisdiction of which was transferred by the Act to the High Court of Justice or the Court of Appeal, were thenceforth to be called solicitors of the supreme court. The title of attorney-general, however, still remains as that of the highest law officer of the crown. The Legal Practitioners Act, 1876, and the Solicitors Act, 1877, enabled solicitors to practice as proctors in the ecclesiastical courts (see **PROCTOR**). The Conveyancing Act, 1881, having made great changes in the practice of conveyancing, it became necessary to place the remuneration of solicitors upon a new basis. This was done by the Solicitors Remuneration Act, passed on the same day as the Conveyancing Act. It provides for the framing of general orders, fixing the principles of remuneration with reference *inter alia* to the skill and responsibility involved, not, as was generally the case before, with reference simply to the length of the documents perused or prepared. General orders in pursuance of the Act were issued in 1882.

In Scotland solicitors in the supreme court are not, as in England, the only persons entitled to act as law agents. They share the privilege with writers to the signet in the supreme court, with solicitors at law and procurators in the inferior courts. This difference is, however, now of little importance, as by the Law Agents Act, 1873, any person duly admitted a law agent is entitled to practise before any court in Scotland. In the United States the term solicitor is used in some States in the sense which it bore in England before the Judicature Act, *viz.*, a law agent practising before a court of equity.

Many of the great public offices in England and the United States have their solicitors. In England the treasury solicitor fills an especially important position. He is responsible for the enforcement of payments due to the treasury. The office of queen's proctor is now combined with that of treasury solicitor. Under his powers as queen's proctor the treasury solicitor acts as administrator of the personal estate of an intestate which has lapsed to the crown, and intervenes in cases of divorce where collusion is alleged (see **DIVORCE**). Since the Prosecution of Offences Act, 1884, he has also acted as director of public prosecutions. In the United States the office of solicitor to the treasury was created by Act of Congress in 1830. His principal duties are to take measures for protecting the revenue and to deal with lands acquired by the United States by judicial process or vested in them by security for payment of debts.

SOLICITOR-GENERAL See **ATTORNEY GENERAL**. The position of the solicitor-general for Scotland in the main corresponds with that of the English solicitor general. He is next in rank to the lord-advocate. In the United States the office of solicitor general of the United States was created by Act of Congress in 1870.

SOLIMAN, or **SULEIMAN**, sultan of the Ottomans, surnamed The Magnificent, born about 1490, was the only son of Selim I, whom he succeeded in 1520. He died while he was besieging Sziget in Hungary, on September 5, 1566. See **TURKEY**.

SOLIMAN, or **SULEIMAN**, shah of Persia. See **PERSIA**, vol. viii p. 639.

SOLINGEN, a Prussian town, in the province of the Rhine, stands on a height near the Wupper, 13 miles east-by-south of Düsseldorf. It is one of the chief seats of the German iron and steel industry, its specialty consisting in all kinds of cutting implements of steel. Solingen sword-blades have been celebrated for centuries, and probably form part of the equipment of every modern army, while bayonets, knives, scissors, surgical instruments, files, steel frames, and the like are also produced in enormous quantities. These articles are largely made by the workmen at their own homes and supplied to the depôts of the large

dealers, there are about 30,000 workers in steel in Solingen and its vicinity. The population of the town in 1885 was 18,643, of whom three fourths were Protestants.

Solingen is an ancient place, and received its town charter in 1374. Sword blades have been made here since the early part of the Middle Ages, and tradition affirms that the art was introduced during the crusades by smiths from Damascus.

SOLIS, **ANTONIO DE** (1610–1686), Spanish dramatist and historian, was born in 1610 at Alcalá de Henares, and studied law at Salamanca, where he is said to have produced a comedy which was acted in 1627. About 1640 he became secretary to the duke of Oropesa, whom he accompanied in various official missions, in 1654 he became one of the secretaries of Philip IV, and afterwards he was appointed chronicler. In his later years he joined one of the religious orders. He died at Madrid in 1686.

Of the nine extant plays of Solis two at least have some place in the history of the drama,—*El Amor al Uso* ("Love à la Mode") having afterwards been adapted by T. Corneille, while *La Gitanilla de Madrid* ("The Gipsy of Madrid"), itself founded on the "novela" of Cervantes, has been made use of by Rowley and Middleton, P. A. Wolff, and, directly or indirectly, by other more recent authors. The titles of the remaining seven are *Triunfos de Amor y Fortuna*, *Erudice y Orfeo*, *El Alcazar del Secreto*, *Las Amazonas*, *El Doctor Carlino*, *Un Bobo hace ciento*, and *Amparar al Enemigo*. The *Historia de la Conquista de Mexico*, covering the three years between the appointment of Cortes to command the invading force and the fall of the city, deservedly ranks as a Spanish prose classic. It first appeared in 1684, there have been numerous reprints, the most recent being that published with notes by Revilla (Paris, 1858), an English translation by Townshend appeared in 1724. A volume of *Poesias sagradas y humanas* by Solis was published in 1692, and several unimportant letters of his may be read in the *Epistolario Español* of Rivadeneyra.

SOLOMON (Hebrew שְׁלֹמֹה, *Shēlōmō* for *Shēlōmōn*, "man of peace", the English form follows the *Σολόμων* of NT and Josephus, the Latin *Salomo* agrees with *Σαλώμων*, one of several variant forms shown in MSS of the LXX), son of David by Bathsheba, and his successor in the kingdom of Israel. The reign of Solomon has been sketched in **ISRAEL** (vol. xii p. 405), and his relation to the philosophical and proverbial literature of the Hebrews, the so-called *chokma*, or "wisdom," has been critically considered in the article **PROVERBS**. The political system of Solomon fell to pieces at his death, but the fame of his wisdom and splendour in succeeding generations was all the greater that none of his successors at Jerusalem was in a position to rival him. The many floating and fragmentary notes of various dates that have found a place in the account of his reign in the book of **KINGS** (q.v.) show how much Hebrew tradition was occupied with the monarch under whom the throne of Israel reached its highest glory, and that time only magnified in popular imagination the proportions of so striking a figure appears alike in the unfriendly picture of Solomon in the Song of Solomon (originally, it would seem, sketched in the Northern Kingdom, however much it may have been retouched and overlaid by additions of later date—see **CANTICLES**) and in the monologue of **ECCLESIASTES** (q.v.) placed in the mouth of the wise king who had tasted all that life can offer by one of the latest writers of the Old Testament. In the apocryphal book of Wisdom, again, the composition of an Egyptian Hellenist, who from internal evidence is judged to have lived somewhat earlier than Philo, Solomon is introduced uttering words of admonition, imbued with the spirit of Greek philosophers, to heathen sovereigns. The so-called Psalter of Solomon, on the other hand, a collection of Pharisee psalms written in Hebrew soon after the taking of Jerusalem by Pompey, and preserved to us only in a Greek version, has nothing to do with Solomon or the traditional conception of his person, and seems to owe its name to a transcriber who thus distinguished these newer pieces from the older "Psalms

of David.¹² In New Testament times Solomon was the current type alike of magnificence and of wisdom (Matt vi 29, Luke xi 31). But Jewish legend was not content with this, and, starting from a false interpretation of Eccles. i 8, gave him sovereignty over demons, to which were added (by a perversion of 1 Kings i 33) lordship over all beasts and birds, and the power of understanding their speech. These fables passed to the Arabs before the time of Mohammed (Nābigha, i 22), found a place in the Koran, and gave Solomon (Suleiman) a lasting fame throughout the Moslem East. The story of Solomon, the hoopoe, and the queen of Sheba in sur xxvii of the Koran closely follows the second Targum to Esther i 2, where the Jewish fables about him may be read at large. Solomon was supposed to owe his sovereignty over demons to the possession of a seal on which the "most great name of God" was engraved. See Lane, *Arabian Nights*, introd., note 21, and chap i note 15.

SOLOMON, SONG OF. See CANTICLES.

SOLOMON, WISDOM OF. See APOCRYPHA.

SOLOMON ISLANDS, an extensive group of islands, the largest and as yet least known of any in the Pacific Ocean, though among the very first that were discovered. They form a double chain of seven large and many small islands, extending for over 600 miles in a north west and south-east direction between 5° S lat, 154° 40' E long, and 10° 54' S lat, 162° 30' E long. The northern extremity stretches to within 120 miles of New Ireland, the south-eastern point to 200 miles west of Santa Cruz, and the nearest portion of New Guinea lies about 400 miles to the south west of the group.² See vol xix Plate III.

The Solomon Islands vary considerably both in size and character. It is as yet doubtful which of them is the largest, but seven are from 50 to over 100 miles in length and from 15 to 30 miles in breadth, several must therefore equal the county of Cornwall in area. They are well watered, though the streams seem to be small, their coasts afford some good harbours.³ All the large and some of the smaller islands appear to be composed of ancient volcanic rock, with an incrustation of coral limestone showing here and there along the coast. Their interior is mountainous, and Guadalcanal, where there is an active volcano, reaches an altitude of 8000 feet. Malanta and Christoval are over 4000, Isabel and Choiseul 2000 feet high. The mountains of the latter fall steep to the sea, and the whole of its north-east portion forms an elevated wooded plain. There is some level land in Bougainville, which is also said to possess an active volcano. Every traveller has extolled the beauty and fertility of the islands. In San Christoval deep valleys separate the gently rounded ridges of its forest-clad mountains, lofty spurs descend from the interior, and, running down to the sea, terminate, on the north, in bold rocky headlands 800 to 1000 feet in height, while, on the south, they form an shelter bays of deep water. On the small high island of Florida there is much undulating grass land, interspersed

with fine clumps of trees, but patches of cultivated land surround its numerous villages, and plantations on the hill sides testify to the richness of its soil. To the south of Choiseul lies a small cliff girt islet, Simla (Shortland's Eddystone), with a peak ending in a crater 1200 feet high, on the side of which are a fumarola and two boiling springs. It is inhabited, and has a small safe harbour. Surgeon Guppy, late of H.M.S. "Lark," has recently made valuable geological observations in the north and south of the group. The whole chain of islands appear to be rising steadily, and traces of ancient upheaval are very general,—for instance, Treasury Island, where a coral incrustated volcanic peak has been raised 1200 feet, and the atoll of Sta Anna, the ring of which now stands hundreds of feet above the present level of the sea. Some of the smaller islands are of recent calcareous formation. Barrier and fringing reefs, as well as atolls, occur in the group, but the channels between the islands are dangerous, chiefly from the strong currents which set through them.

The climate is very damp and debilitating. The rain fall is unusually heavy. Fever and ague prevail on the coast, but it is likely that the highlands will prove much more healthy. The dry season, with north west winds, lasts from December to May.

A comparatively shoal sea—under 1000 fathoms—surrounds the Archipelago, and, including the New Britain and Admiralty Islands, stretches to New Guinea and thence to Australia. This sufficiently accounts for the Papuan character of its fauna, of which, however, it is the eastern limit, in spite of the fact that this shoal water extends to the extreme south of the New Hebrides. Here the strange little marsupial the cuscus (*Phascogale*) is still to be met with, the hornbill, the coelacanth, the crimson loré, and birds of a dozen other genera have already been discovered, "all," as Wallace remarks, "highly characteristic of the Moluccas and New Guinea, and quite unknown in any of the more remote Pacific islands." But, like the New Hebrides, the Solomon Islands possess a megapode (*M. brevirostris*) which is peculiar to itself. An alligator frequents the coast, and the sea teems with fish. Insects seem to be fairly well represented. The flora has been even less studied than the zoology, but it also shows strong Papuan affinities. Vegetation is most luxuriant: unbroken tracts of magnificent forest clothe the mountains, where sandalwood, ebony, and lignum vitae have already been found. Mangrove swamps are common on the coasts.

The Solomon Islanders, excepting those of Bougainville and Rennell in the south, and Ontong Java in the north—who are pure Polynesians—are a small sturdy Melanesian race taller in the north than in the south, but averaging about 5 feet 4 inches for men, and 4 feet 9 inches for women. They are well proportioned, with nicely rounded limbs. Projecting brows, deeply sunk dark eyes, short noses, either straight or arched, but always depressed at the root, and moderately thick lips, with a somewhat receding chin, are general characteristics. The expression of the face is not unpleasant. The mesocephalic appears to be the predominant form of skull, though this is unusual among Melanesian races. In colour the skin varies from a black brown to a copperish hue, but the darker are the most common shades. The hair is dark, often dyed red or fawn. Crisp, inclining to woolly, it naturally hangs in a mop of ringlets 3 to 8 inches in length, but, when carefully tended, it forms one smooth bush—the usual fashion for both sexes. Epilation is practised, little hair, as a rule, grows on the face, but hairy men are not rare.⁴ Skin diseases are prevalent.

The Solomon Islanders are intelligent, of a quick and nervous temperament, crafty, thrifty, and revengeful, yet, quickly amenable to good treatment, they make faithful servants. They are fond of dancing, their music is a monotonous chant with an

⁴ On the islands in Bougainville Strait tribes with lank, almost straight, black hair and very dark skin are found. The mountains of race, with whom the coast tribes wage perpetual war and for whom they express great contempt.

¹ The most ancient tradition, that of the LXX, gives Solomon no part in the authorship of the canonical psalter, see vol. xx p. 29.

² *Islands of the Archipelago*.—The larger are—in the eastern chain, Bougainville, Choiseul, Isabel, Malanta, and in the western chain, New Georgia, Guadalcanal (often misspelt Guadalcanar), San Christoval. The smaller are—Buka (the most northern), Shortland, Treasury, Faro, Simla (Eddystone), Purlana, Hammond, Marsh, Sava, Buena Vista, Anna, Ngela (Florida), Ulava (Contraverté), Ugi, Three Sisters, Mendana mentions seeing near Buena Vista a small island in a state of violent eruption, he named it Sesarga. Ontong Java is a group of coral islands in the north east, but it does not, geographically, form part of the group.

³ Blanche Bay, Bougainville, Port Praslin, Isabel, Maravo, New Georgia, Port Wiseman, Florida, Curaçoa Harbour in Marau Sound, Guadalcanal, Recherche Bay, Makira Bay, and Vanga Harbour, San Christoval.

History—The Spanish navigator Mendana must be credited with the discovery of these islands, though it is somewhat doubtful whether he was actually the first European who set eyes on them. He sailed from Callao in 1567, by command of the governor of Peru, to discover the southern continent, the presumed existence of which in the then unknown region between America and Asia had already given rise to much speculation, but he seems to have been strangely unfortunate. Sailing west he discovered only a few coral islets (the Ellice group) until, having crossed more than 7000 miles of ocean, he fell in with an archipelago of large islands. By their size and position he considered them to form part of the land

³ Of the island manufactures fine specimens may be seen in the British, Cambridge, and Maidstone museums

* The dates of his birth and death are approximate: 638 and 559

594 B.C. he was summoned under the constitutional title of "archon" to undertake the work of sweeping political reforms, which, in consequence of bitter party strifes and the poverty and indebtedness of the small farmers or proprietors of Attica, were sorely needed. The Athenian like the Roman debtor had often sunk, under the legalized oppression of his creditor, into an actual slave, and had from time to time been sold and exported. Many poor creatures had fled away from home, and were supporting themselves by the labour of their hands in foreign countries. Many men who still clung to their little properties could, with all their pinching, barely keep their heads above water. The governing classes themselves felt that a crisis was at hand, and they appealed to Solon and made him practically dictator. Had he chosen to work on the popular discontent, he might have easily crushed the aristocracy and become a despot, or, as the Greeks called it, a tyrant, as many had done in other states of Greece by coming forward as champions of the people against the great ruling families. Solon obeyed a nobler impulse and aimed at saving his country without too violent a revolution. His first step was to give immediate relief to the poor debtor, to the wretchedly impoverished small farmer or proprietor, and to interpose between him and his creditor and landlord. On very many of the little properties of Attica were to be seen stone pillars with the name of the mortgagee and the amount of the mortgage inscribed on them. By a relief law, "a shaking-off of burdens" (*σεισάχεια*), he annulled all mortgages, justifying no doubt so extreme a measure by the harshness of the contracts imposed by mortgagees on needy tenants and proprietors and by the urgent necessity of prompt release for the multitude of such small debtors. Thus the "mortgage pillars" were swept away and the land was once more free. Such a setting aside of the rights of property, expedient as it may have been under circumstances of acute public distress, must have inflicted a heavy loss on the wealthier class, and the landlord and the mortgagee would also have a fair claim for relief. This, it appears, Solon accomplished by a device which has been variously explained, a devaluation of the currency which relieved to a considerable extent—27 per cent, according to Grote's¹ calculation—the wealthier debtors of the landlord and mortgagee class. Grote here remarks that, had Solon cancelled all debts and contracts, there would have been no need to interfere with the currency and lower the standard of money. His relief law could not have been so sweeping and revolutionary as it has sometimes been represented. There was no redistribution or confiscation of the land, no universal remission of debts. For the great majority of the people indeed there was substantial relief. The land was free from incumbrance, and the small cultivator had a fresh start in life, there was no imprisonment or slavery for the debtor, and it would seem that debtors who had sought refuge abroad were purchased back and restored to their homes. Such on the whole appears to have been the character of Solon's first great reform, though some of the details remain obscure. The reconstruction of the political system on the principle that every citizen was to have a share in the government was Solon's next work. A few noble families, Eupatrids, as they were called, had hitherto had all the power in their own hands. Solon made property the measure of political power, and confined the higher offices of state to the wealthiest citizens, but election to these offices was to be made by the whole body of the people, the tenure of office was limited as to time, and an account had to be rendered publicly as to its exercise. The citizens were distributed into four classes

¹ *History of Greece*, ch. xl.

according to a graduated scale of property, the first class being alone eligible to the archonship or highest office and to military and naval commands. The actual administration of public affairs was thus restricted to the wealthy few. The second class were the knights or horsemen—the men who could keep a war horse for the service of the state, these were assessed at three fifths of the amount of the first class. The third class answered to our yeomen, and had to serve as heavy armed infantry. These three classes were subject to direct taxation in the form of a graduated income tax, which was, however, simply an extraordinary tax, levied only in special emergencies at varying amounts per cent on a citizen's rateable property, as set down in a public schedule. The fourth and lowest and most numerous class, which supplied light troops and sailors for the fleet, was exempt from all direct taxation, but paid indirect taxes, it would be made up of small farmers, tradesmen, and artisans, and consist in fact of quite the poorest and humblest class of citizens. Its members could not hold any office, but they had a large amount of political power through their votes in the popular assembly which elected the magistrates and called them to account, and through the very great judicial powers with which they were intrusted, and in virtue of which the Athenian juror practically decided questions both of fact and of law. Solon's constitution thus gave the people ample means of protecting themselves from misgovernment and oppression, every magistrate being directly responsible to them. Not that Solon himself contemplated anything like pure democracy, there is every reason to believe he shrank from it, but pure democracy was pretty sure to follow as soon as the people distinctly realized their power. Solon's council of 400, taken exclusively from the first three classes, must have been meant to furnish the popular assembly with political guidance, and this it did by preparing and introducing measures for discussion and superintending its meetings and exercising some direction over its proceedings. It is impossible for us to define its peculiar functions precisely. It was, however, ultimately under the control of the popular assembly, by which probably it was annually elected, and to which it had annually to render an account. We are not to suppose that either the council or the popular assembly originated with Solon. What he really did was to put them on a new footing, and to the latter, which previously in all probability had hardly any weight or influence, he gave greatly enlarged powers. The archons and magistrates and the council itself were elected by the popular assembly, and were responsible to it for good behaviour during their term of office. In this assembly met the citizens of all four classes, and consequently the great majority of its members would be poor men and almost peasants. The voting was by show of hands, every voter was allowed to speak, and in the voting there was no distinction of classes, all being on a perfectly equal footing. Although theoretically they could not originate any measure, but had to accept for discussion what had been prepared for them by the council, they had an absolute power of veto, and, as the election of the council was in their hands, it must have been easy for them to get that body to bring forward any proposal which they might wish to discuss. Thus it may be truly said that Solon laid the foundation of the future democracy. And through the *Heliaea*, as it was called,—a body of 6000 citizens annually elected by lot to act as jurors for the trial specially of political offences,—the people acquired a complete control over public affairs. There was but one proviso the Athenian juror must be upwards of thirty years of age. In the Athenian courts which were formed out of these 6000 citizens the functions of judge and jury

were united in one and the same person, and political questions were continually decided when, as often happened, a citizen was put on his trial for some alleged illegal or unconstitutional proposal. By such means popular rights and privileges were effectually protected, and the democratic character of the constitution enlarged and confirmed, as we see in the subsequent history of Athens. Solon, indeed, retained (he did not create) the famous senate of the Areopagus, and aimed at making it respected and capable of exercising a general superintendence over the morals and social life of the citizens. It was to be an aristocratic body, consisting only of archons who had acquitted themselves well and honourably during their year of office. It seems that he did not attempt to prescribe to it any special or particular duties, but that he rather trusted to its making its influence felt from the fact that it was, as every one knew, composed of men of acknowledged merit and ability. Consequently, as Thirlwall observes (*Hist. of Gr.*, ch. vi), "it could only exercise its powers with advantage as long as it retained the confidence of its fellow-citizens, when that was lost it became time that its legal authority should cease." Solon evidently felt that, for a time at least, there must be checks on popular government. Had it been limited to him that under his constitution power must finally drift down to the lowest social stratum, he would perhaps have replied that he had endeavoured to supply the entire people with a political training which should by degrees qualify them for absolute self government.

Solon encouraged commerce and manufacturing industry, and drew a number of settlers from foreign parts to Athens, on condition of their paying an annual tax and putting themselves under the protection of a citizen who was to be their legal representative—their "patrons," according to Roman phrase. These settlers (*μετοίκαι*, "metics") had none of the political privileges of the Athenian citizen, and they could not acquire landed property. Many of them, however, flourished and grew rich, and had every reason to be satisfied with their position, which, in a kindly and tolerant community like that of Athens, was continually improving. Solon, too, like all the legislators of antiquity, endeavoured to regulate every department of life, compelling the attendance of the youths from sixteen to eighteen at the public gymnastic schools, and requiring them to serve the next two years on garrison duty. Restraints were put upon women as to their appearance in public, and even as to their mourning at funerals. Solon's punishments were for the most part rather lenient, and indicated a humane and generous temper. It is of course not to be supposed that all the details of his legislation were maintained, but they undoubtedly left their mark on the Athenian character.

Having done his work, Solon left Athens and travelled for ten years in Egypt, Cyprus, and Asia, gathering fresh stores of knowledge for himself and giving counsel to others. One would like to believe the beautiful story Herodotus tells of his interview with Cræsus, king of Lydia, whom he warned with the memorable saying that "no man must pronounce any man happy till we have seen his end." Unfortunately, Cræsus did not begin to reign till several years after Solon's travels, and with Grote we must be content to take the story as merely an "illustrative fiction." On his return to Athens in his old age he found the old feuds once more raging, and Pisistratus, his kinsman, and his friend in past days, intriguing for power. The two men had, it seems, a sincere respect for one another, but Solon protested against the complete surrender of the government to Pisistratus, the danger of which he publicly pointed out, though without effect. The crisis ended in the rule, in many respects unenlightened and

beneficent rule, of Pisistratus and his sons, of which Solon lived only to see the first beginning. He died, soon after having made his honourable protest, at the age of eighty, leaving behind him the good effects of a work which only a man of rare intelligence and wide sympathies could have accomplished. He was something of a poet, and several fragments of his poems, written generally with a practical purpose, have come down to us, and throw light on his political aims and sentiments.

Grote and Thirlwall in their histories of Greece give a full account of Solon's legislation. Plutarch's life of Solon, not a very critical performance, is our chief original authority. (W. J. B.)

SOLOTHURN See **SOLEURE**.

SOMALI, **SOMĀL**, a Hamitic people of east Central Africa, mainly confined to the eastern "horn" of the continent, which from them takes the name of Somali Land, probably the Punt of the Egyptian records. Here they are contumacious towards the north-west with the kindred Afars (Dankali), and elsewhere with the more closely related Gallas, from whom they are separated on the south-west by the river Juba. Tadjura Bay, with the lower course of the Hawash, is usually given as the north-west frontier, but, according to the recent explorations of Abargues de Sostan in eastern Abyssinia, there appears to be here an overlapping of the three peoples, the Somali encroaching on the Afar domain north of Tadjura Bay nearly to the parallel of Asab Bay (13° N.), while the Dawari Gallas penetrate between this Somali tribe and the lower Hawash eastwards to the coast at Obok (12° N.). A line drawn from the Strait of Babel Mandeb through the Harrar district and the headwaters of the Hannes river (Webbe Shebeyh or "Leopard river") southwards to the equator at the mouth of the Juba will roughly define the landward frontier of the Somali territory, which is elsewhere sea-girt,—by the Gulf of Aden on the north, by the Indian Ocean from Cape Guardafui to the equator.

Our first contact with the Somali people may be said to date from the English occupation of Aden in 1839. But, notwithstanding the early visits of Cruttenden, Ch. H. Johnston, Captain Burton, and one or two others, very little was known about them before the seizure of Berberah by the Egyptians in 1871. This event led to the establishment of permanent relations with the coast tribes, and was followed by several excursions into the interior, of which the most fruitful in results have been those of Sacconi, Revon, F. L. James, Panlit-elike, Von Hardegg, and Josef Menge, the last three bringing our information down to the year 1885. From the reports of these observers the true relations of the Somali have been gradually determined, and we now know that they form a distinct branch of the eastern ("Ethiopic") Hamitic stock, of which the other chief members are the neighbouring Gallas and Afars, the Abyssinian Agan, and the Beja (Bishari) of the steppe lands between the Nubian Nile and the Red Sea. Their close affinities both in physical type and in speech with the surrounding Gallas are obvious, and like them they are described as a fine race,¹ tall, active, and robust, with fairly regular features, but not free from an infusion of Negro blood, as shown both in their dark, often almost black complexion, and still more in their kinky and curly woolly hair, sometimes short, sometimes long enough to be plaited in tresses hanging down to the shoulders.

¹ Captain Wharton, who has been recently surveying the Somali coast, describes the coast tribes as "the most handsome race of men and women he had ever seen," but with magnificent physique (Proc. Zool. Acclimat. Soc., vol. vi, p. 100). Captain F. M. Hunter also writes of them as "a fine race of people, with oval faces, high cheekbones, and well-defined features, bright red lips, and light brown eyes." (Proc. Zool. Acclimat. Soc., vol. vi, p. 100.)

² The occurrence of these features in the Somali is due to the fact that all these features are in some degree present in the Gallas.

the Gallas also they are still in the tribal state, broken up into an endless number of clans and septs, variously grouped by different writers. According to Captain Guillaum¹ there are three main divisions—the Aji on the north and north-east coast, the Hawiya on the south east coast, and the Rabbanwin in the interior. But these are reduced by James to two, Isak and Darode (apparently the Edur and Darrud of older observers), with several main branches as under—

- Isak {
 - Habr Gerhaji, south from Berberah, beyond the coast range.
 - Habr Tynich, east from Berberah, north of the coast range.
 - Habr Awal, Berberah district.
- Darode {
 - Mejertain, east coast from Guardafui to 4° north.
 - Dolbohanti, Nogat River.
 - Warsanguah, north coast, west from Guardafui.
 - Marchan, between the Mejertain and Ogadain.
 - Ogadain, Webbe basin, and widespread in interior.

To these, however, must be added the powerful Gadabirsi west from Berberah and the Isa (Issa) of the Hawash basin, besides the three low-caste tribes dispersed amongst the others,—Tomal (ironworkers), Ebur (dealers in charms), and Midgau (ostrich breeders).

The Somali, who are mainly Mohammedans of a somewhat fanatical type, are a fierce lawless people, impatient of control, and yielding a reluctant obedience even to their own rulers. Hence the tribal chiefs enjoy little more than a nominal authority, although some of the more powerful amongst them affect the title of sultan. At present the great Habr Gerhaji nation appears to be split into two sections, each under a chief claiming this rank. All go armed with spear, shield, and short sword, the latter exactly like that of the ancient Egyptians, whom the Somali are otherwise said to resemble more than any other African people. The weapons are freely used in their disputes, although the tribal laws against homicide are severe, heavy fines of camels or other property being imposed, which must be paid either by the criminal or the community. They are great talkers, keenly sensitive to ridicule, and quick tempered, although amenable to reason if they can be induced to argue the point. According to the character of the soil and climate they live a settled or nomad life, in some places breeding numerous herds of camels, goats, and fat tailed sheep, in others growing large crops especially of durrah, or collecting the gums—frankincense and myrrh—for which the land has always been famous. The Marehan (properly Murreyhan) tribe is said to have given its name to the myrrh, which is obtained in the greatest perfection in their district, although the term seems too old to admit of this derivation, and is more probably connected with a Semitic root *mar, mur*—bitter. Through the ports of Berberah and Zeyla a considerable export trade to Arabia, Egypt, and India is carried on with these articles and the other natural products of the country, such as hides, horns, ostrich feathers, coffee of a very fine quality, indigo, salt. But the natives take little part in this movement, which from remote times has been in the hands of the Indian Lantians settled at various points on the coast. In 1870-80 the total value of the exports is estimated at about £140,000.

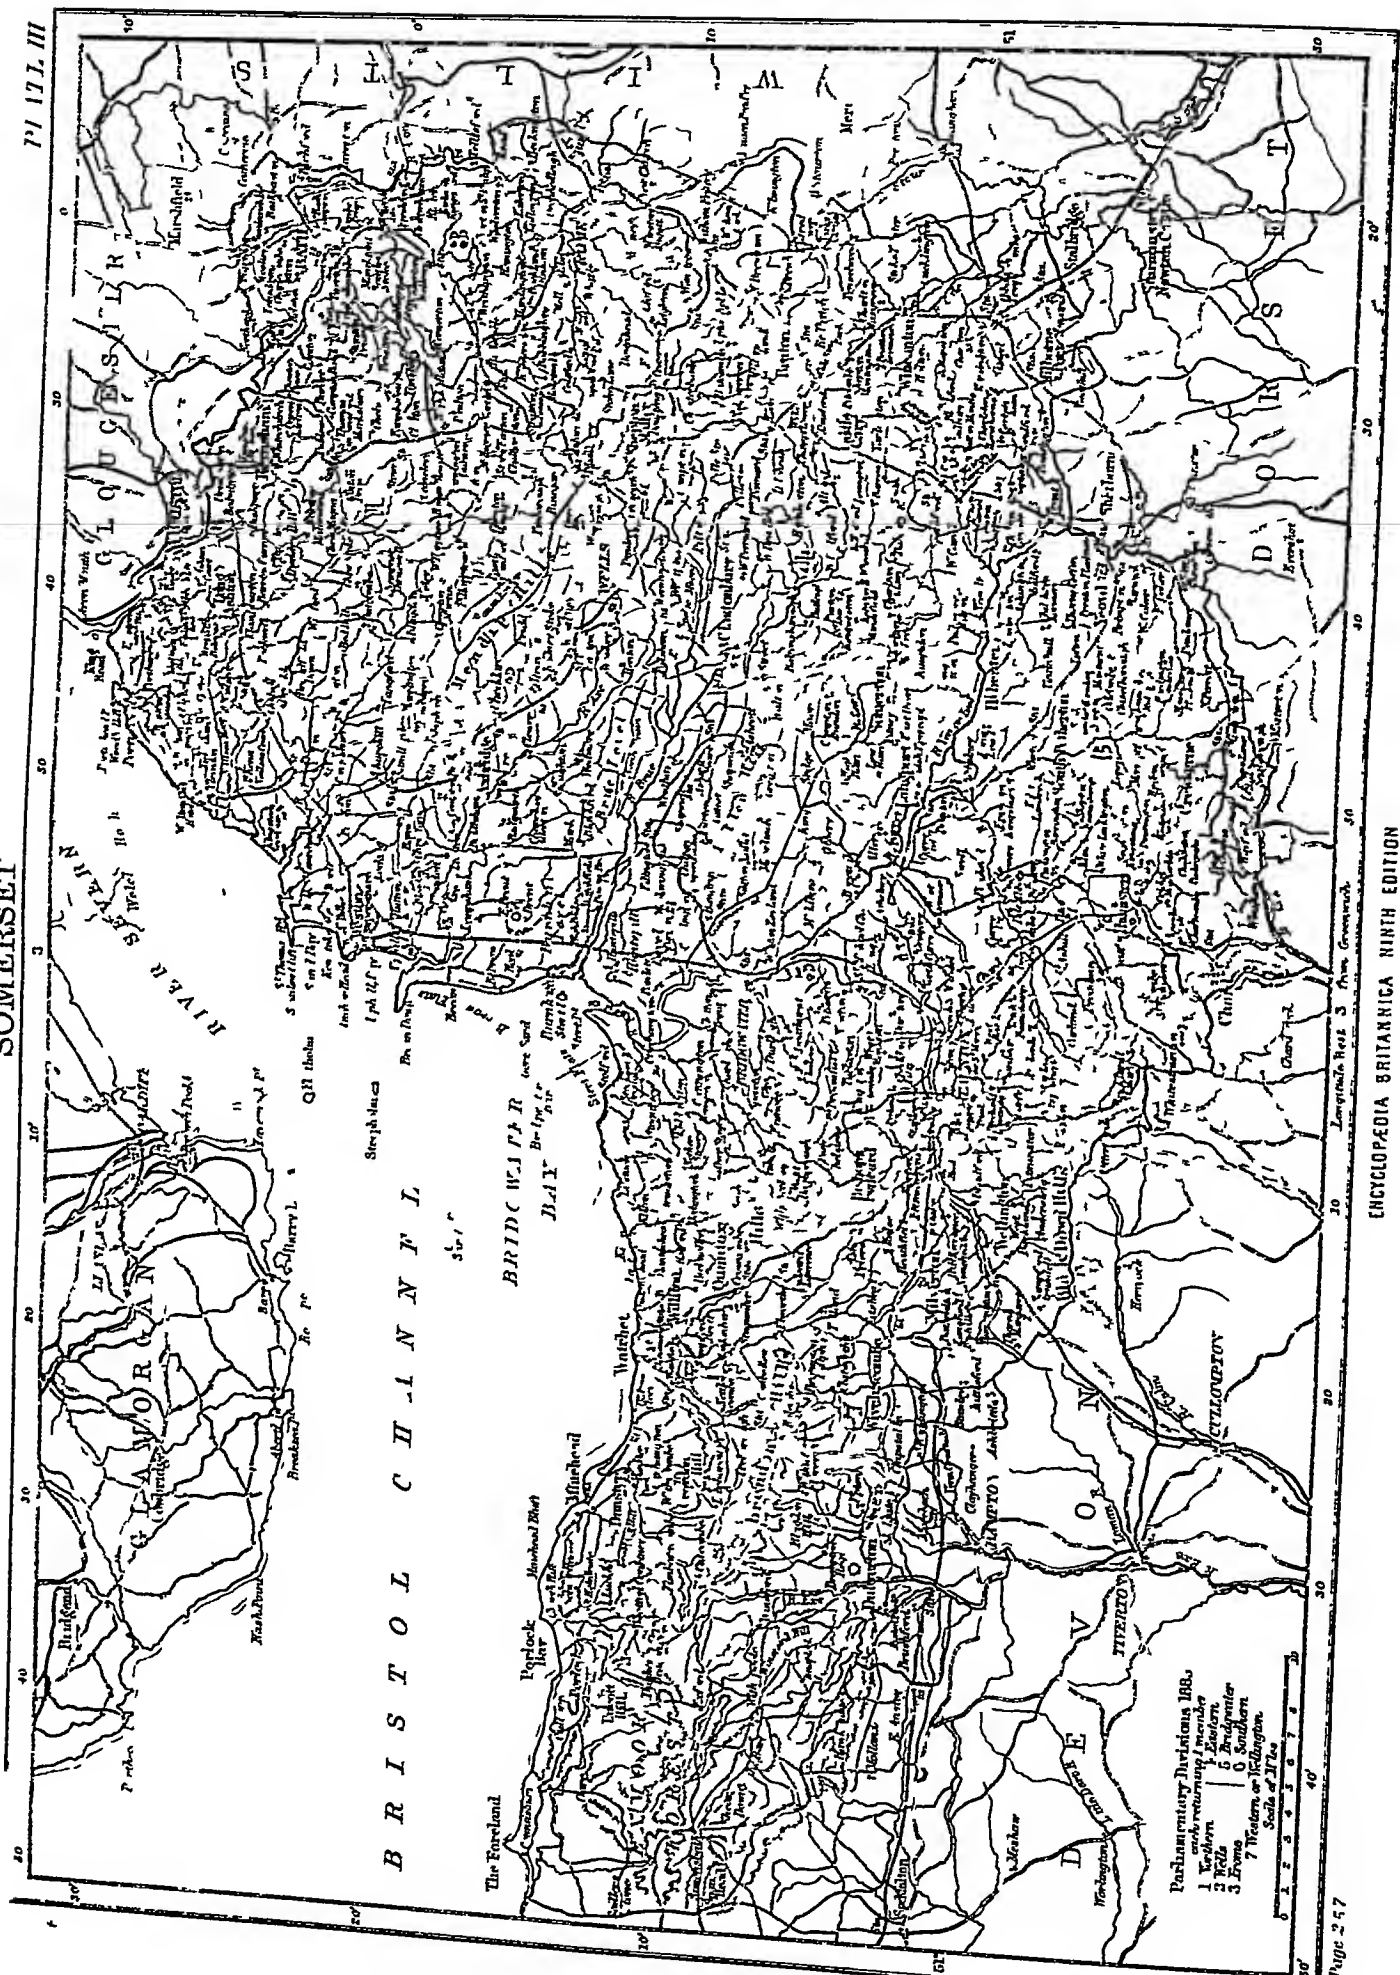

Like many other Mohammedan peoples, the Somali claim Arab descent, their progenitor having been a certain Sherif Ishak b. Ahmad, who crossed over from Hadramaut with forty followers about five hundred years ago. Other traditions go farther back, tracing their origin to the Himyaritic chiefs Samhah and Samamah, said to have been coeval with a King Afrisah, who is supposed to have conquered Africa about 400 A.D. These legends should perhaps be interpreted as pointing at a series of Arab immigrations, the last two of which are referred to the 13th and 15th centuries. But these intruders seem to have been successively absorbed in the Somali stock, and it is remarkable that the Arabs never succeeded in establishing permanent settled or nomad communities in this region, as they have done in so many other parts of the continent. Their influence has been very slight even on the Somali language, whose structure and vocabulary are essentially Hamitic, with marked affinities to the Galla on the one hand and to the Danhal (Afar) on the other. Captain Hunter's Grammar, with verses and vocabularies (Bombay, 1880), utilizing the materials published by General Rigby in the *Proceedings of the Bombay Geographical Society* (1849), is the only comprehensive treatise on the language, which appears to be spoken with great uniformity throughout the whole of Somali Land. Hunter mentions an eastern and a western dialect, differing, however, but little from one another, which is the more remarkable that there is no written standard and little oral literature, beyond some proverbial sayings, short stories inculcating certain moral teachings, and some simple love-songs. Although the rhythm is defective, these chants are

¹ Documents sur l'histoire, &c., de l'Afrique Orientale, 1856-59

not lacking in poetical ideas, and often betray an unexpected refinement of feeling not inferior to that of similar compositions amongst more civilized peoples. (A. H. K.)

SOMERS, JOHN (1652-1716), was born on March 4, 1652, at Worcester,—the eldest son of John Somers, an attorney in large practice in that town who had formerly fought on the side of the Parliament, and of Catherine Caeerne of Shropshire. After being at school at Worcester he was entered as a gentleman commoner at Trinity College, Oxford, and afterwards studied law under Sir Francis Winington, who became solicitor general, and joined the Middle Temple. He appears, in addition to his legal studies, to have written several poems and pamphlets. He soon became intimate with the leaders of the country party, especially with Essex, Russell, and Algernon Sidney, but never entered into their plans so far as to commit himself beyond recall. He was the author of the *History of the Succession of the Crown of England, collected out of Records, &c.*, and was reputed to have written the *Just and Modest Imputation of the Two Last Parliaments*, which was put forward as the answer to Charles II's famous declaration of his reasons for dissolving them. This, however, was by Sidney, though probably Somers was responsible for the final draft. When the grand jury of Middlesex threw out the bill against Shaftesbury, and were vehemently attacked for so doing, Somers wrote in defence of the rights of grand jurors. In 1683 he was counsel for the sheriffs Pilkington and Shute before the Court of King's Bench, and secured a reputation which continually increased until the trial of the seven bishops, in which he was junior counsel. "Somers rose last. He spoke little more than five minutes, but every word was full of weighty matter and when he sat down his reputation as an orator and a constitutional lawyer was established." In the secret councils of those who were planning the revolution Somers took a leading part, and in the Convention Parliament was elected a member for his native town. He was immediately appointed one of the managers for the Commons in the conferences between the Houses, and in arguing the questions whether James II had left the throne vacant by abdication and whether the Acts of the Convention Parliament were legal—that parliament having been summoned without the usual writs—he displayed great learning and legal subtlety. He was further distinguished by being made chairman of the committee which drew up the celebrated Declaration of Right. On May 9, 1689, Somers was made solicitor-general. He now became William III's most confidential adviser. In the controversy which arose between the Houses on the question of the legality of the decision of the Court of King's Bench regarding Titus Oates, and of the action of the Lords in sustaining this decision, Somers was again the leading manager for the Commons, and has left a clear and interesting account of the debates. He was next employed in January 1690 as chairman of the select committee of the House of Commons on the Corporation Bill, by which those corporations which had surrendered their charters to the crown during the last two reigns were restored to their rights, but he refused to associate himself with the violent measures of retaliation which the Whigs on that occasion endeavoured to include in the bill. In April a speech by him carried through the Lower House, without opposition, the bill which declared all the laws passed by the Convention Parliament to be valid. As solicitor general he had to conduct the prosecution of Preston and Ashton in 1691, and did so with a moderation and humanity which were in marked contrast to the customs of the former reigns. He was soon after appointed attorney-general, and in that capacity strongly

SOMERSET

opposed the bill for the regulation of trials in cases of high treason. On March 23, 1693, the great seal having meanwhile been in commission, Somers was appointed lord keeper, with a pension of £2000 a year from the day on which he should quit his office, and at the same time was made a privy councillor. He had previously been knighted. Somers now became the most prominent member of the Junto, the small council which comprised the chief members of the Whig party. When William left in May 1695 to take command of the army in the Netherlands, Somers was made one of the seven lords-justices to whom the administration of the kingdom during his absence was entrusted, and he was instrumental in bringing about a reconciliation between William and the princess Anne.

The question of improving the currency now became pressing, and Somers was the author of the bold suggestion that a proclamation should be issued simultaneously all over the kingdom, announcing that henceforth all clipped and hammered coins were to be reckoned only by weight. But all possessors of such coins might, by delivering them up on a certain day, receive a note entitling them to draw from the treasury at a future time the difference between the actual and nominal values. The difficulties of the plan, however, rendered its adoption impossible. In April 1697 Somers was made lord chancellor, and was created a peer by the title of Baron Somers of Evesham. When the discussion arose on the question of disbanding the army, he summed up the case against disbanding, in answer to Trenchard, in a remarkable pamphlet called "The Balancing Letter." In August 1698 he went to Tunbridge Wells for his health. While there he received the king's letter announcing the first Partition Treaty, and at once replied with a memorandum representing the necessity in the state of feeling in England of avoiding further war. When the king, on the occasion of the Disbanding Bill, expressed his determination to leave the country, Somers boldly remonstrated, while he clearly expressed in a speech in the Lords the danger of the course that was being taken. Hitherto Somers's character had kept him free from attack at the hands of political opponents, but his connexion in 1699 with the notorious Kidd, who, being sent out to put down the pirates in the Indian Ocean, turned pirate himself, and to the defraying of whose expedition Somers had given £1000, afforded an opportunity, the vote of censure, however, proposed upon him in the House of Commons for giving Kidd a commission under the great seal was rejected by 199 to 131. The attack was renewed shortly on the ground of his having accepted grants of crown property to the amount of £1600 a year, but was again defeated. On the subject of the Irish forfeitures a third attack was made in 1700, a motion being brought forward to request the king to remove Somers from his counsels and presence for ever, but this again was rejected by a large majority. In consequence, however, of the incessant agitation, William now requested Somers to resign, this he refused to do, but gave up the seals to William's messenger. In 1701 he was impeached by the Commons on account of the part he had taken in the negotiations relating to the Partition Treaty in 1698, and defended himself most ably before the House, answering the charges *seriatim*. The impeachment was voted and sent up to the Lords, but was there dismissed. On the death of the king Somers retired almost entirely into private life. He was, however, active in 1702 in opposing the Occasional Conformity Bill, and in 1706 was one of the managers of the union with Scotland. In the same year he carried a bill regulating and improving the proceedings of the law courts. He was made president of the council in 1708 upon the return of the Whigs to

power, and retained the office until their downfall in 1710. From this time his powers of mind rapidly declined, and after being almost imbecile for six years he died of apoplexy on April 26, 1716. Somers was never married, but left two sisters, of whom the eldest, Mary, married Charles Cocks, whose grandson, Sir Charles Cocks, Bart., became the second Lord Somers in 1784.

For a contemporary character of Somers Addison's paper in the *Freeholder* for May 14, 1710, should be referred to, and there is in Macaulay's *History* (vol. iv. p. 53) an eloquent and worthy tribute to his stainless character and comprehensive learning. A catalogue of his publications will be found in Walpole's *Royal and Noble Authors* (O. A.).

SOMERSET, a maritime county in the south west of ^{Plate} England, bounded E by Wiltshire, S E by Dorset, S W ^{III} and W by Devonshire, N W by the Bristol Channel, and N by Gloucestershire. The total area of land and water is 1,049,815 acres or 1610 square miles.

The shape of the county is determined by the nearly rectangular bend taken by the coast not far from Bridgewater. It falls into three natural divisions, which answer remarkably to the three waves of West-Saxon conquest and to the parliamentary divisions as they stood till the latest changes. The range of Mendip, breaking off from the high ground in the east of the county, completely shuts off the northern part, between Mendip and Bristol, itself hilly. Mendip itself, running slightly north-westward towards the Channel, has for its summit a tableland sloping much more gently to the north than to the south. Its most striking though not its highest points are towards the Channel, where it ends in the promontory of Brean Down, while the Steep Holm stands as an outpost between the hills of Somerset and those of Glamorgan. The sides of Mendip are broken by many passes or *combes*, the most marked of which are Ebbor rocks near Wells and the greater pass of Cheddar cliffs, whose varied outlines, in the many turns of the pass, are probably the most noteworthy of their kind in England. Between Mendip and the region of loftier hills in the south lies a great alluvial plain, known generally as Sedgemoor, but with different names in different parts. This plain, intersected by ditches known as *rhines*, and in some parts rich in peat, is broken by isolated hills and lower ridges, of which the most conspicuous are Brent Knoll near Burnham, the Isle of Avalon, rising with Glastonbury Tor as its highest point, and the long low ridge of Polden ending to the west in a steep bluff. In the south is Blackdown on the border of Devonshire, the higher range of Quantock (highest point 1262 feet) stretching to the sea, and to the west again the mountainous region of Brendon and Exmoor, commonly believed by tourists to be part of Devonshire. Here are hills of much greater height and bolder outline, the highest point being that of Dunkery (1709 feet) above Porlock. The two principal rivers are the Lower Avon and the Parrot. The Avon, after forming for a short distance the boundary with Wilts, crosses the north eastern corner of the county, encircling Bath, and forms the boundary with Gloucestershire till it reaches the sea 6 miles beyond Bristol. It is navigable for barges as far as Bath. The Parrot from South Perrott in Dorset, on the borders of Somerset, crosses the centre of the county north westwards by Bridgewater, receiving the Ivel or Yeo and Cary on the right, and the Isle and Tone on the left. Among other streams are the Axe, which rises at Wookey Hole in the Mendips and flows north-westward along their base to the Bristol Channel near Blackrock, the Brue, which rises to the east of Bruton, near the borders of Wiltshire, and enters the Bristol Channel near the mouth of the Parrot, and the Exe (with its tributary the Barle), which rises in Exmoor forest and passes southward into Devon.

The diversified surface of the county is accounted for by the variety and complexity of its geological structure. The Old Red Sandstone, composed of sandbanks and mudbanks of a land-locked lake, is met with in the Mendip Hills and on the banks of the Avon, but presents no feature of importance. The Devonian rocks, after plunging beneath the Triassic strata of the low ground between Williton and Taunton, rise again to the surface in the well-wooded Quantock Hills. The Carboniferous strata occupy a considerable area between Bristol and the Mendip Hills, forming a portion of the Bristol and Somerset coalfield. The Carboniferous limestone, built up mainly of petrified shells and corals, forms a truncated arch in the Mendip Hills, which owe their steepness and rugged contours to its compact and jointed structure, and their ravines and caves to atmospheric influences and to streams acting on the formation at and below the surface. It overlaps to the south the plain of Somerset, and plunges northwards under the coal measures and Triassic rocks, reappearing in isolated and picturesque masses. The coal-measures, which have a thickness of about 7000 feet, include an upper and a lower series, separated by beds of grit about 2000 feet in thickness, also containing beds of coal (see *COAL*, vol. VI. p. 52). It is supposed that similar beds underlie the marshes to the south at a depth of from 1000 to 1200 feet. A large portion of the Carboniferous rocks are covered unconformably with the New Red Sandstone and Liassic and Oolitic strata. Triassic rocks prevail over the whole western area, from the Mendips to Exmoor. The highly fossiliferous Rhætic strata rest on the grey marls of the Trias, and constitute the lower part of the bold scarp of the Lias limestone and clays of the ranges from the sea to the Poldens. Plunging beneath the Oolitic strata, they occupy a large but scattered area in the east between Yeovil and Bath, and these in their turn pass under the Cretaceous strata of the serried Blackdown Hills. A large extent of the county is occupied by alluvial deposits. Caves are common in the body of the

hills, among which the greatest are the bone cave near Banwell, the stalactite caves at Cheddar, and Wookey Hole. Hard by the last-named is the hyæna cave discovered in 1852, and explored in 1857-63, when, besides animal remains belonging to a great variety of species, flint and chert implements were also discovered.

Minerals.—Though the exposed area of the coalfield of Somerset is only about 14 square miles, it is estimated to extend over 238 square miles. The amount of coal raised within the county in 1884 was 843,437 tons, valued at £205,202. Spithouse iron ore has been long worked in the Brendon Hills, but the industry is declining,—26,041 tons, valued at £13,021, having been obtained in 1858 and only 3582 tons, valued at £2619, in 1884. Lead mining has been carried on in the Mendips from time immemorial, but the industry is of much less importance than it was in earlier times, the amount of dressed lead ore obtained in 1884 being only 664 tons, of lead obtained in smelting 178 tons, of silver obtained from the lead 2760 ounces, and the value of the ore at the mines £1055. Next to coal the most important mineral production is freestone from the Oolitic strata, the largest quarries being in the neighbourhood of Bath. Copper and manganese are obtained in small quantities, as well as fuller's earth, marl, cement from the Lias, and ochre.

Railways.—The county is so completely intersected by branches of the Great Western Railway in the north and west, and of the South Western in the south and east, that there is perhaps no hamlet more than seven miles from a railway station.

Manufactures.—Woollen and worsted goods are manufactured in a large number of towns, silk at Frome, Taunton, and Shepton Mallet, gloves at Yeovil, Taunton, and other places, crapes at Dulverton and Shepton Mallet. There are large potteries at Bridgwater and Weston super Mare, at the former town and at Bath there are extensive carriage works, and there are paper mills on several of the streams. Most of the commerce of the county passes through Bristol, which is situated mainly in Gloucestershire.

Agriculture.—In the hilly districts much of the land is uncultivated and barren, although affording some pasturage for sheep. There are large tracts of rich meadow land along the banks of the rivers, and the vale of Taunton is well adapted for wheat. On account of the extensive damage frequently caused in the lower grounds by floods, the Somerset Drainage Act was passed by parliament 11th June 1877, providing for the appointment of commissioners to take measures for the drainage of lands in the valleys of the Parret, Ille, Yeo, Brue, Axo, Cary, and Tone, where extensive damage is frequently caused by floods. The following table gives a classification of the holdings in 1875 and 1880—

	50 Acres and under		From 50 to 100 Acres		From 100 to 300 Acres		From 300 to 500 Acres		From 500 to 1000 Acres		Above 1000 Acres		Total	
	No.	Acres	No.	Acres	No.	Acres	No.	Acres	No.	Acres	No.	Acres	No.	Acres
1875	11,099	136,069	1,812	132,687	2,304	336,216	341	127,111	62	27,966	4	7,204	16,672	836,401
1880	13,200	140,212	1,760	129,939	2,349	402,421	303	152,740	72	43,169	4	6,786	17,933	804,570

Out of a total area of 1,049,815 acres there were 867,469 acres in 1885 under culture, of which 625,957 acres, or nearly three fourths, were in permanent pasture, 58,863 under clover and rotation grasses, 115,005 under corn crops, 61,650 green crops, 560 flax, and 5434 fallow. Of the corn crops the largest area—49,199 acres—was occupied by wheat, barley occupying 27,834 acres, oats 24,783, beans 11,349, pease 1576, and rye 164. About one half of the area under green crops was occupied by turnips, which covered 30,891 acres, mangold coming next with 10,867 acres, while vetches occupied 8881, potatoes only 7517, and carrots 212. Horses in 1885 numbered 34,848, of which 23,229 were used solely for purposes of agriculture. The number of cattle was 236,899, of which 110,068 were cows and heifers in milk or in calf. Cattle feeding and dairy farming are the principal branches of husbandry. Large numbers of cattle are brought from Dorset to be grazed on the rich Somersetshire meadows. The district east and west of Wells with that of Cheddar, is famed for the cheese of that name, and cheese is also extensively made in other districts. Sheep, chiefly Leicesters and Southdowns, are grazed, the number in 1885 being 601,020. The number of pigs in 1885 was 111,719, and of poultry 414,803. In the extent of its orchards, chiefly apple trees, Somerset comes next among the counties of England to Hereford and Devon, the area in 1885 being 23,660 acres. The apples are principally made into cider, which is the common drink of the peasantry. The area under market gardens was 759 acres, and under nursery grounds 170 acres. There were 39,850 acres in 1881 under wood.

According to the Landowners Return Somerset in 1873 was divided among 32,765 owners, possessing 940,483 acres, at an annual value of £2,705,393, 18s., or an average value all over of about £2, 17s. 6d. per acre. There were 20,370 proprietors, or about 62 per cent., who possessed less than one acre, and 19,246

acres were common land. The following possessed over 9000 acres each—Viscount Portman, 24,171, Sir T. D. Acland, 16,320, Sir J. H. G. Smyth, 13,543, Earl of Ilchester, 13,169, G. F. Luttrell, 12,732, Earl of Carnarvon, 12,732, Earl Poulett, 10,118, A. G. Lethbridge, 9103, and Sir A. A. Hood, 9008.

Administration and Population.—Somerset comprises forty hundreds, two liberties (Hampton and Claverton, Mells and Leigh), the cities of Bath (population 61,814 in 1881) and Wells (4634), part (38,181) of the city of Bristol, and the municipal boroughs of Bridgwater (12,007), Chard (2411), Glastonbury (3719), Taunton (16,614), and Yeovil (8479). For parliamentary purposes the county, which was formerly divided into East, Mid, and West Somerset, was by the Act of 1885 parted out in seven separate divisions—North, South, East, West (or Wellington), Bridgwater, Frome, and Wells. The borough of Frome was in 1885 merged in its county district. The city of Bath returns two members, and a portion of the East Division of Bristol is within the limits of the county. In addition to the boroughs the following urban sanitary districts are situated within the county—Burnham (1904), Clevedon (4869), a rising watering place, Frome (9377), Midsomer Norton (4422), Radstock (3074), Shepton Mallet (5322), Street (2514), Wellington (6360), Weston super Mare (12,884), a favourite watering place, and Wivoliscombe (1624). The county has one court of quarter sessions, and is divided into twenty-two petty and special sessions. The city of Bath and the borough of Bridgwater have commissions of the peace and separate courts of quarter sessions, and the city of Wells and the borough of Yeovil have commissions of the peace. The county contains 489 civil parishes, with parts of three others. Ecclesiastically it corresponds closely to the diocese of Bath and Wells. From 273,577 in 1801 the population had increased in 1831 to 403,795, in 1861 to 443,916, in 1871 to 463,483, and in 1881 to 469,109, of whom 220,582 were

males and 248,527 females. The number of persons to an acre in 1881 was 0.45 and of acres to a person 2.24.

History.—Somerset, the land of the *Sumorsetan*, is one of the West Saxon shires which grew by gradual conquest from the Welsh, as opposed to the Mercian shires mapped out round a town and called by its name. The name may well enough be what it seems at first sight, as it is called in Welsh *Wlad yr Haf*, and in Latin some times *præstera regis*. Anyhow the land bears the name of the folk. There has never been any central town or acknowledged capital, though Somerton bears a name cognate with the land. Assizes, elections, and the like have been held at different places at different times. There is no distinct name for the land earlier than the English conquest, it does not preserve the name of any British tribe, like the neighbouring *Danmonia* and *Durotriges*. But there are abundance of remains both of prehistoric and of Roman times, beginning with the stones which have given their name to *Stanton Drew* and the great giant's chamber at *Wollon*. Many of the hills are crowned with camps, as *Cadbury*, seven acres in extent, the remains on *Hampton Down*, near *Bath*, the fortress of *Macsbury Castle*, remarkably well preserved, the camp on *Worlebury Hill*, containing a number of hut circles, *Dolbury* camp on the Mendips, of great extent and surrounded by a stone ditch and rampart, and *Norton Fitzwarren*, near *Taunton*. At *Bath* the Romans had an important city, *Aqua Sulis*, on the line of the "fosse" which crossed the centre of Somerset, skirting the eastern ridges of the Mendips by *Shepton Mallet* and *Ilchester* (*Ichale*) to the ancient *Moridunum*. From *Ilchester* an other Roman road passed to *Durnovum* (*Dorchester*). From *Brean Down*, where there was a Roman port, a road crossed south eastwards by the Mendips and *Shepton Mallet* to *Sorbidunum* (*Salisbury*). The completeness of the Roman occupation is evidenced not only by the variety and importance of the relics which have been discovered, but by the wide area over which they are spread. That land was wrought by the Romans in the Mendips is evidenced by *laminae* found at various places bearing the imperial stamp, from the remains of old pottery kilns that have been discovered it would appear that this industry then as now was of considerable importance, the foundations of Roman villas are very common, and there are many remarkably fine specimens of Roman pavements. After the withdrawal of the Roman power, the district formed part of the British kingdom of *Dumonia* or *West Wales*, and it plays its part in the legends of *Arthur*, which seem to have grown out of the history of that kingdom. The religious history gathers round the *Isle of Avalon* and its monastery, known in Welsh as *Ynysvryn* and in English as *Glastonbury*, names of somewhat uncertain origin and use, and which must not be pressed too strongly. Wild legends connect the place with *Joseph of Arimathea* and a crowd of saints from *Ireland* and elsewhere. It is enough to say that it undoubtedly was a religious house, though perhaps of no very great antiquity, before the English conquest reached so far, and that it was the one great church (as *Exeter* was the one great city) which lived on uninterruptedly through the English conquest. That conquest began in 577 with the campaign of *Cerwin*, when, after the battle of *Deorham*, he took *Gloucester*, *Cirencester*, and *Bath* and advanced his frontier to the *Ave*. This was the last heathen conquest, before the second advance under *Cenwall* the West Saxons had become Christians. His two victories in 652 and 658 carried the English frontier to the *Parret*, and took in *Glastonbury*. The later stages are less clear, *Cenwall* in 672 "drove the Britons to the sea," and *Ine* fought with the Welsh king *Gorest* in 710 and made *Taunton* a border fortress at some time before 722. By this time the conquest was complete. In the Danish wars *Ælfred* in 878 found shelter at *Athelney* and then went forth to his victory at *Edington* (*Edington* in *Wiltshire*), after which peace was made with the Danes at *Wodmore*. We hear of several later Danish invasions, but the Danes never made any settlements. Under *Edward the Confessor* Somerset formed part of the earldom, first of *Swegen* and then of *Harold*. It probably submitted to the Norman Conqueror after the taking of *Exeter* in 1068, and an English revolt in the next year was put down. In 1088 *Ilchester* stood a siege in the cause of *William Rufus*, and the county plays its part in the wars of *Stephen*. During the Middle Ages onward to the period of the civil war the historical events of Somerset—with the exception of the episode of *Porkin Warbeck*, who seized and abandoned *Taunton* in 1497—are chiefly associated with *Bristol* (*q.v.*). The great mass of the people, especially those in the towns, took the *Parliament* side in the great conflict, but from 1643 to 1645 the shire was in the hands of the Royalists, with the exception of *Taunton*, which held out heroically under *Blake* till relieved by *Fairfax* on the 11th May of the latter year, which was followed by other successes until the whole district was regained by the *Cromwellian* party. The continuance of a strong *Puritan* feeling in the district was evidenced forty years later by the support given to the *Monmouth* rebellion, the latest historical event of special importance connected with the county.

The history of the county and its existing remains of antiquity have been largely affected by its ecclesiastical history. First part

of the single bishopric of *Wessex* at *Winchester*, then of that of *Shorborne*, the land of *Sumorsetan* became a distinct diocese in 900 with its bishopstool at *Wells*. The seat and style of the bishop have changed several times, but the boundaries of the diocese have changed remarkably little. Nowhere except in *Sussex* have the shire and the diocese been so nearly the same thing at all times. The great possessions of the bishopric and of the abbey of *Glastonbury* led to a remarkable lack of castles in the mid part of the county, and also tended to overshadow all other ecclesiastical foundations. Even in the other parts of the county castles are not a prominent feature, and no monastic church remains perfect except those of *Bath* and its cell *Dunster*. To *Bath* the bishopstool was removed in 1088, and after some shiftings, including a transfer to *Glastonbury*, the double style of *Bath* and *Wells* was established, the monks of *Bath* and the canons of *Wells* forming two separate chapters for the bishop. At the dissolution of monasteries *Bath* was suppressed, *Wells* became the sole chapter, but the name of *Bath* was still kept in the bishop's style. The monastery of *Glastonbury* was destroyed, as were most of the smaller monasteries also. Of those which have left any remains, *Woodspring*, *Montacute* (*Gloucester*), *Cleeve* (*Cistercian*), and *Michelney* are the most remarkable. *Athelney*, founded by *Ælfred* on the spot where he found shelter, has utterly perished. *Montacute* and *Dunster* fill a place in both ecclesiastical and military history. The castle of *Robert of Mortain*, the Conqueror's brother, was built on the peaked hill (*mons acutus*) of *Leodgaresburh*, where the holy cross of *Waltham* was found. The priory arose at the foot. *Dunster*, one of the few inhabited castles in England, stands on a hill crowned by an English mound. Besides these there are also remains at *Nunney* and *Castle Cary*, but castles are not a strong point in Somerset antiquities. In ecclesiastical architecture the two great churches of *Wells* and *Glastonbury* supply a great study of the development of the earlier Pointed style out of Romanesque. But the architectural strength of the county lies in its great parish churches, chiefly in the Perpendicular style, of which they present a characteristic variety. In the same style among greater churches are *Bath Abbey*, *Sherborne* minster in *Dorset*, and *Saint Mary Redcliffe* at *Bristol* (locally in Somerset and till lately in the diocese), a parish church on the type of a minster. Of earlier work there is little Norman, and hardly any Primitive Romanesque, but there is a characteristic local style in some of the smaller buildings of the 14th century. The earlier churches were often cruceiform, and sometimes with side towers. In domestic remains no district is richer, Somerset stands alongside of *Northamptonshire* owing to the abundance of good stone in both. *Clovedon Court* is a very fine inhabited manor house of the 14th century, and the houses, great and small, of the 15th, 16th, and 17th centuries are endless. Indeed, the style has never quite gone out, as the gable and the mullioned window have lingered on to this day. *Barrington Court* in the 16th century and *Montacute House* in the 17th are specially fine examples. There are also some very fine barns, as at *Glastonbury*, *Wells*, and *Pilton*.

Among the more illustrious natives of Somersetshire are *Dunstan*, *Roger Bacon*, *John Locke*, *Admiral Blake*, *Pym*, *Bishop Ken*, *Folding*, *Cudworth*, and the poet *Daniel*.

See *Collinson, History of Somersetshire* 7 vols., 1791; *Phelps, Modern Somersetshire* 1839, *Proceedings of the Somersetshire Archaeological and Natural History Society*; *Evton Somerset Survey*, 2 vols., 1850; *Hunt, Diocesan History of Bath and Wells*, 1880; *Breeman, English Towns and Districts*, pp. 103 sq.

SOMERSET, *Edward Seymour, Duke of* (c. 1500–1552), eldest brother of *Jane Seymour*, *Henry VIII's* third wife, was created earl of *Hertford* in 1537, on the birth of his nephew, afterwards *Edward VI*. In 1544 he commanded in the war with *Scotland*, and sacked *Edinburgh*. Next year he again commanded against the *Scots*, and he was employed by *Henry* in many important negotiations throughout the latter part of his reign. On the accession of *Edward VI* he was made protector by the council, and was soon afterwards created duke of *Somerset*. He at once made use of his power to encourage the extreme Reformers, and a general destruction of ecclesiastical works of art was the result. In September 1547, finding the *Scots* unwilling to listen to his proposals for a marriage between *Edward* and *Mary Stuart*, he marched an army into *Scotland* and won the battle of *Pinkie Clough*,—a worthless victory, which only threw *Scotland* into the arms of *France*. War with that country followed, and the result was the loss of *Boulogne*. Equally disastrous was the protector's domestic policy. He was animated by a dislike of arbitrary government, and by a desire to improve the condition of the poor, but was at the same time a slave to his own ambition. He

pushed on the Protestant Reformation with inconsiderate speed, repealed the Treason Acts of Henry VIII's reign, and issued a commission to inquire into agricultural distress. The agitation into which these measures threw the country produced insurrections in the west and east, which were with some difficulty suppressed. Irritated by his arrogance, rashness, and incapacity, the council, in October 1549, turned against him, deprived him of the protectorate, and confined him in the Tower. Released in 1550, he recovered much of his influence through the misgovernment of his successors, and contemplated a return to power at their expense. His plans being discovered, he was tried on a charge of felony, and executed on January 22, 1552. His popularity was immense, and in some respects deserved, but he aspired to a tyranny, and had he retained or recovered power he would have gone far towards ruining the nation.

SOMERSET, ROBERT CARR, EARL OF (c 1590-1645), came of a good Scottish family, the Kers of Inchmurchie. The date of his birth seems uncertain, but he was a lad when James I. ascended the English throne. When this event occurred Carr gave up the position which he had hitherto occupied as page at the Scottish court, and sought for a time to make his fortune in France. Returning to England he entered the service of Lord Hay, and soon attracted the attention of the king. Entirely devoid of all higher qualities, Carr was endowed with good looks, excellent spirits, and considerable personal accomplishments. These advantages were sufficient for James, who knighted the young man and at once took him into favour. In 1607 an opportunity enabled the king to confer upon him a more substantial mark of his affection. Sir W. Raleigh had through his attainder forfeited his life interest in the manor of Sherborne, but he had previously executed a conveyance by which the property was to pass on his death to his eldest son. This document was, unfortunately, rendered worthless by a flaw which gave the king eventual possession of the property. Acting on Salisbury's suggestion, James resolved to confer the manor on Carr. The case was argued at law, and judgment was in 1609 given for the crown. Lady Raleigh received some compensation, apparently inadequate, and Carr at once entered on possession. His influence was already such that in 1610 he persuaded the king to dissolve the parliament, which had shown signs of attacking the Scottish favourites. Next year Carr was made an English peer, and took his seat in the House of Lords as Viscount Rochester. Shortly afterwards he became a privy councillor, and in the autumn of 1613 he was created earl of Somerset. In 1614 he became lord chamberlain.

He was now at the zenith of his power, but the event had already occurred which was to prove his ruin. Before 1609, while still only Sir Robert Carr, he had commenced an intrigue with Lady Essex. In 1613 that lady set about procuring a divorce from her husband, with the object of afterwards marrying Carr. James favoured the cause of Lady Essex, the court pronounced a decree of divorce, and in December 1613 she married the earl of Somerset. Ten days before the court gave judgment, Sir Thomas Overbury, who apparently knew facts concerning Lady Essex which would have been fatal to her success, was poisoned in the Tower. No idea seems to have been entertained at the time that Lady Essex and her future husband were implicated. For two years more Somerset continued to exercise a paramount influence over James, and it was not till 1615 that his arrogant behaviour began to alienate the king. His fall was due, however,

not to the loss of the king's favour nor to the combination at court against him, but to the discovery of the circumstances of Overbury's death. In July 1615 Somerset obtained a full pardon from the king for all offences which he might have committed. Soon afterwards the truth about the murder came out. Coke and Bacon were set to unravel the plot. After four of the principal agents had been convicted and punished, the earl and countess were brought to trial. The latter confessed, and of her guilt there can be no doubt. Somerset's share is far more difficult to discover, and probably will never be fully known. The evidence against him rested on mere presumption, and he consistently declared himself innocent. Probabilities are on the whole in favour of the hypothesis that he was not more than an accessory after the fact. James let matters take their course, and both earl and countess were found guilty. The sentence was not carried into effect against either culprit. The countess was pardoned immediately. The earl appears to have refused to beg forgiveness by concession, and it was not till 1621 that he obtained his pardon. Thenceforward he disappears from public view. He died, without heirs, in 1645.

SOMERVILLE, previous to its recent incorporation with Boston a city of the United States, in Middlesex county, Massachusetts, lying on Mystic river, 2 miles north west of the Boston state house. It was named in honour of Richard Somers, a naval officer, and was incorporated as a city in 1872. The population was 24,973 in 1881. Glass works, bottle works, flour mills, a bleachery, and a brass-tubing factory are among the industrial establishments.

SOMERVILLE, MARY (1780-1872), scientific writer, was the daughter of Admiral Sir William George Fairfax, and was born 26th December 1780 in the manse of Jedburgh, the house of her mother's sister, wife of Dr Thomas Somerville, author of *My Own Life and Times*, whose son was her second husband. She received a rather desultory education, and mastered algebra and Euclid in secret after she had left school, and without any extraneous help. In 1801 she married her cousin Captain Samuel Graig who died in 1806, and in 1812 she married another cousin, Dr William Somerville, inspector of the army medical board, who encouraged and greatly aided her in the study of the physical sciences. After her marriage she made the acquaintance on the Continent and in London of the most eminent scientific men of the time, among whom her talents had attracted attention before she had acquired general fame, Laplace paying her the compliment of stating that she was the only woman who understood his works. Having been requested by Lord Brougham to translate for the Society for the Diffusion of Useful Knowledge the *Mécanique Céleste* of Laplace, she greatly popularized its form, and its publication in 1831 under the title of *The Mechanism of the Heavens* at once made her famous. She was elected an honorary member of the Royal Astronomical Society, and her bust by Chantrey was placed in the hall of the Royal Society of London. Her other works are the *Connection of the Physical Sciences* (1834), *Physical Geography* (1848), and *Molecular and Microscopic Science* (1869). Much of the popularity of her writings is due to their clear and crisp style, and the underlying enthusiasm for her subject which pervades them. In 1835 she received a pension of £300 from Government. She died at Naples 28th November 1872. In the following year there appeared her *Personal Recollections*, consisting of reminiscences written during her old age, and of great interest both for what they

reveal of her own character and life and the glimpses they afford of the literary and scientific society of bygone times

SOMME, a department of northern France, formed in 1790 of a large part of the province of Picardy (comprising Vermandois, Santerre, Aménois, Pontlueu, Vimeu, and Marquenterre) and a small portion of Artois. It is bounded on the N by Pas de Calais and Nord, E by Aisne, S by Oise, and SW by Seine-Inferieure, and its sea coast extends 28 miles along the English Channel. Two streams flowing into the Channel—the Authie on the north and the Bresle on the south-west—bound it in these directions. The surface consists of great rolling plains, generally well cultivated and very fertile. The highest point, hardly 700 feet above the sea, lies in the south-west, not far from Aumale. From the mouth of the Authie to the Bay of the Somme the coast is lined with a belt of sand dunes about 2 miles broad, behind which is the Marquenterre, a tract of 50,000 acres reclaimed from the sea by means of dykes and traversed by drainage canals. The Bay of the Somme, obstructed by dangerous sand-banks, but containing the three ports of Crotoy in the north, St Valery in the south, and Hourdel in the south-west, has also been considerably encroached upon by the same methods. Next come the shingle banks, behind which the low fields of Cayeux (25,000 acres) have been reclaimed, and then at the hamlet of Ault commence the chalk cliffs, which continue onwards into Normandy. The river Somme traverses the department from south east to north-west for a distance of 125 miles, through a marshy valley abounding in peat. Commanded by Ham, Péronne, Amiens, and Abbeville, this valley forms a northern line of defence for Paris. Apart from the water-power it supplies, the Somme is of great commercial value, being accompanied by a canal all the way from its source wherever it is not itself navigable. From Abbeville to St Valery its lower course forms a maritime canal 165 feet wide, 13 feet deep, and 8 to 9 miles long, capable of bearing at high tide vessels of 300 tons burden. From St Valery to the open sea the channel is bounded on the south by a towing path embankment 2 miles long, and on the north by a dyke, capable of being laid under water, 1 mile long, and there the current hells out a very variable bed accessible at certain tides for vessels of 500 tons. The most important affluents of the Somme—the Ancre from the north-east by way of Albert and Corbie, the Avre from the south east by Roye, and the Selle from the south by Conty—join the main stream at Amiens. The Authie and the Bresle are respectively 65 and 45 miles long. The latter ends in a maritime canal about 14 feet deep between Eu and Treport. The mean temperature is lower than that of Paris (49° Fahr at Abbeville). Rain falls on 175 days per annum (33 inches at Abbeville).

Of the total area of 1,522,520 acres, 1,178,184 acres are under tillage, 68,844 are under meadows and pasture land, 133,837 are occupied by wood, while 30,514 acres are heaths or uncultivated tracts. In 1881 the live stock included 78,069 horses, 940 mules, 6125 asses, 140,512 cattle, 449,675 sheep (wool clip 1117 tons), 82,755 pigs, 21,726 goats, there were also 27,902 hives (116 tons of honey and 36 of wax). The department, especially in the north east, is one of the best cultivated in France. Beetroot for sugar is the staple crop of the Péronne arrondissement, cereals, fodder, oil plants (especially the poppy), hemp, and potatoes are grown throughout the department, the latter more largely on the seaboard. No wine is grown, but the cider harvest of 1883 amounted to 8,904,100 gallons, and beer is a common beverage. In 1884 there were grown 7,072,106 bushels of wheat, 1,810,437 of meslin, 1,008,932 of rye, 1,789,089 of barley, 4207 of buckwheat, 11,197,392 of oats, 4,930,067 of potatoes, 1,161,665 tons of beetroot for sugar, and 208,686 tons of beetroot for fodder, 40 tons of hops, 242 tons of hempseed, 651 tons of hemp fibre, 1123 tons of flax, 5245 tons of colza seed, and 240,311 tons of fodder. Peat cutting (84,335 tons in 1882) gives employment to 2640 hands, the best qualities and the deepest workings being in the valley of the Somme, between

Amiens and Abbeville. The peat of inferior quality is burned on the spot and the ashes used as manure. Textile industries employ 36,000 hands. The linen and hemp manufacture is carried on in dressing establishments and spinning and weaving factories with 50,000 spindles, 2250 power looms, and 4000 hand looms, and the manufactures comprise canvas for packing and sail making, and linen (including damask). Cotton is spun by 72,800 spindles and woven by 745 power looms and 5000 hand looms. Moleskins and velvets for upholstery and other purposes are among the articles manufactured. Wool is wrought in 44 establishments with 124,000 spindles, 120 power looms, and 400 hand looms, producing yarns of all kinds, "Scotch cashmeres," "China satins," serges, merinos, repps, poplins, &c. Tulles, embroidery, laces, ribbons, plush, carpets, cotton, and woollen hose are also manufactured. The last industry employs half the population of Santerre. About 6400 workmen are engaged in the iron and copper industries, steam engine and boiler making, and the production of spinning mill machinery, railway plant, and umbrella frames. The arrondissement of Abbeville is the centre of a great lock manufacture, employing from 4000 to 5000 workmen. There are also chemical factories, bleacheries, tanneries, paper mills (470 hands, product 6108 tons in 1881), saw mills, and soap and candle works. Beetroot sugar is manufactured in 66 establishments (5090 horse power and 6450 workmen). In 1881 53,177 tons of sugar were produced and 2,247,146 gallons of spirit distilled from the molasses and the beet. The total number of hands employed in the industries of the department is 64,000, and the total horse power 13,181. Thirty seven decked boats with 400 hands are engaged in the deep sea fisheries, in the coast fishery 132 small boats with 300 hands. Cereals, horses of the Boulogne or Norman breed, cattle, hemp and linen, and the manufactured goods are the exports of the department. Vegetables and other food stuffs are sent to England, and shingle for the manufacture of earthenware. Besides the raw materials for the manufacturing industries, wines, timber, dyo stuffs, and coal (727,783 tons in 1882) are imported. There are 385 miles of national and 5083 miles of local roads, 119 miles of navigable river or canal, and 379 miles of railway. Administratively the department comprises 5 arrondissements (Amiens, Abbeville, Doullens, Montdidier, and Peronne), 41 cantons, and 836 communes. The population in 1881 was 550,837. The department constitutes the diocese of Amiens, which city (population in 1881, 67,874) is also the seat of a court of appeal and the headquarters of the 2d corps d'armée, in which the department is included.

SOMMERFELD, an industrial town of Prussia, in the province of Brandenburg, lies on the Lubis, 40 miles to the south east of Frankfort-on-the Oder. Its manufactures of woollen cloth are important,—the annual value of the goods produced being upwards of half a million sterling, and it also contains finishing and dye works, an iron foundry, boiler works, &c. The population in 1885 was 11,364, almost all Protestants.

SOMNAMBULISM. See *SLEEP*, *supra*, p 157.

SOMNATH, an ancient but decayed city of peninsular Guzerat, India, with a population in 1881 of 6644, mostly Mohammedans, is situated on a bay of the Arabian Sea, in 20° 53' N lat and 70° 24' E long. The port, which is called Veraval, is distinct from the city proper (Devapattan, Somnath-Pattan, or Prabhas). The latter occupies a prominence on the south side of the bay, is surrounded by massive fortifications, and retains in its ruins and numerous tombs many traces of its former greatness as a commercial port. But the city was most famous for the temple just outside its walls in which stood the great idol or rather columnar emblem of Mahadce called Somnath (Moon's lord), which was destroyed by Mahmud of Ghazni, see the details in vol. xv p 287. For the so-called "gates of Somnath," now at Agra, see GHAZNI, vol. x. p 560. The temple was again plundered by Alí el-Dín in 1300, and appears to have been converted into a mosque. See Yule's edition of Marco Polo, vol. ii p 389 *sq*.

SONDERSHAUSEN. See SCHWARZBURG SONDERSHAUSEN.

SONNET (Ital. *Sonetto*, dim of *Suono*, Fr. *Sonnet*). The sonnet in the literature of modern Europe is a brief peetic form of fourteen rhymed verses, ranged according to prescription. It does not, however, belong to what has been called, properly perhaps, under *RONDEAU* (*q v*), the poetry

of ingenuity. Although in a language like the English it does no doubt require considerable ingenuity to construct a satisfactory sonnet of octave and sestet running upon four rhymes, this ingenuity is only a means to an end, the end being properly that a single wave of emotion, when emotion is either too deeply charged with thought, or too much adulterated with fancy, to pass spontaneously into the movements of pure lyric, shall be embodied in a single metrical flow and return. Whether any given sonnet be composed like that of Pier delle Vigne (of two quatrains with rhymes running a, b, a, b, c, b, c, b, and of two tercets with rhymes running c, d, c, d, e), or whether the verses be arranged (on the authority of Shakespeare and Drayton) in three quatrains of alternate rhymes clinched by a couplet, or, as in the sonnet of Petrarch, in an octave of two rhymes and a sestet of either two or three rhymes,—in each case the peculiar pleasure which the ear derives from the sonnet as a metrical form lies in the number and arrangement of the verses being *prescribed*, and distinctly recognizable as being prescribed. That the impulse to select for the rendering of single phases of feeling or reflexion a certain recognized form is born of a natural and universal instinct is perhaps evidenced by the fact that even when a metrical arrangement discloses no structural law demanding a prescriptive number and arrangement of verses, the poet will nevertheless, in certain moods, choose to restrict himself to a prescribed number and arrangement, as in the cases of the Italian *stornello*, the Welsh *triban*, and the beautiful rhymed short ode of Japanese poetry, for the knowledge of which we are indebted to Mr Chamberlain. And perhaps if space permitted us to probe the matter deeply, we should find that the recognized prescription of form gives a sense of oneness that nothing else save the refrain can give to a poem which, being at once too long for a stanza in a series and too short to have the self-sustaining power of the more extended kinds of poetic art, suffers by suggesting to the ear a sense of the fragmentary and the inchoate. It is not then merely the number of the verses, it is also their arrangement as to rhymes,—an arrangement leading the ear to expect a prescribed sequence and then satisfying that expectation,—which entitles a form of fourteen verses to be called a sonnet.

Hence the so-called irregular sonnets of S. T. Coleridge, which lead the ear of the reader to expect the pleasure of a prescribed arrangement when what they have to offer is a pleasure of an exactly opposite kind—the pleasure of an absolute freedom from prescribed arrangement—are unsatisfactory, while (as the present writer has often pointed out) the same poet's fourteen line poem, "Work without Hope," in which the reader expects and gets freedom from prescription, is entirely satisfactory. This same little poem of Coleridge's also affords an excellent illustration of another point in connexion with the sonnet. If we trace the history and the development of the sonnet from Pier delle Vigne to Rossetti we shall find that the poet's quest from the very first has been to write a poem in fourteen verses so arranged that they should, better than any other number and arrangement of verses, produce a certain melodic effect upon the ear, and an effect, moreover, that should bear iteration and reiteration in other poems similarly constructed. Now if we ask ourselves whether, beautiful as is this poem, "Work without Hope," taken as a single and original metrical arrangement, we should get out of a series of poems modelled line for line upon it that pleasure of iteration which we get out of a series of Petrarchan sonnets, we shall easily see why the regular sonnet of octave and sestet on the one hand, and what is called the Shakespearean sonnet on the other, have survived all other competing forms.

In modern Europe the sonnet has always had a peculiar fascination for poets of the first class—poets, that is, in whom what we have called poetic energy (or *Poetia*) and plastic power are equally enlivened. It would seem that the very fact that the sonnet is a recognized structure suggestive of mere art—suggestive in some measure, indeed, of what Schiller would call "art" in art—has drawn some of the most passionate poets in the world to the sonnet as the medium of their sincerest utterance. Without being coldly artificial, like the rondeau, the *tristan*, the *ballade*, the *millonelle*, &c., the sonnet is yet so artistic in structure, its form is so universally known, recognized and admired as being artistic, that the too formal and artificial reality of the poet's emotion may be in a certain degree veiled, and the poet can win for a form which is in itself the deepest secrets of the heart which could otherwise only find expression in purely dramatic forms.

That the sonnet was invented, not in Provence as French critics pretend, but in Italy in the 13th century is pretty clear, but by whom it still remains an open question. Mr S. Waddington (*Sonnets of Young Waddington*) and several other contemporary critics attribute to Francesco the honour of having invented the form. But Mr F. A. Symonds has reminded us that the sonnet is *l'innanzi*, *Predich' amore*, attributed to Pier delle Vigne, secretary of state in the Sicilian court of Frederick, has claims which no student of early Italian poetry can ignore.

As regards English sonnets, whether the Petrarchan and the Shakespearean are really the best of all possible forms we need not inquire. But, inasmuch as they have become so vital and so dominant over other poetic forms that we never begin to read the first verse of an English sonnet we expect to find one or other of the prescribed rhyme arrangements, any departure from the prescribed arrangement—even though the result be such a magnificent poem as Shelley's "Ozymandias" disappoints the expectation, baffles the ear, and brings with it that sense of the fragmentary and the inchoate to which we have before alluded. If, however, some writer should arise with sufficient originality of metrical endowment and sufficient poetic power to do what Keats, in a famous experiment of his tried to do and failed,—impress the public ear with a new sonnet structure, impress the public ear so powerfully that a new kind of expectance is created the moment the first verse of a sonnet is recited,—then there will be three kinds of English sonnets instead of two.

With regard to the Petrarchan sonnet, all critics are perhaps now agreed that, while the form of the octave is invariable, the form of the sestet is absolutely free, so that the emotions should govern the arrangement of the verses. But as regards the division between octave and sestet, Mr Mark Pattison says, with great boldness, but perhaps with truth, that by blending octave with sestet Milton missed the very object and end of the Petrarchan scheme. Another critic, however, Mr Hall Caine, in his preface to *Sonnets of Three Centuries*, contends that by making "octave flow into sestet without break of music or thought" Milton consciously or unconsciously invented a new form of sonnet, that is to say, Milton, in his use of the Petrarchan octave and sestet for the embodiment of intellectual substance incapable of that partial disintegration which Petrarch himself always or mostly sought, invented a species of sonnet which is English in impetus, but Italian, or partially Italian, in structure. Hence this critic, like Mr William Sharp (*Sonnets of this Century*), divides all English sonnets into four groups—(1) sonnets of Shakespearean structure, (2) sonnets of octave and sestet of Miltonic structure, (3) sonnets of contemporary structure, i.e., all sonnets on the Petrarchan model in which the metrical and intellectual "wave of flow and

ebb" (as originally formulated by the present writer in a sonnet on the sonnet, which has appeared in most of the recent anthologies) is strictly observed, and in which, while the rhyme-arrangement of the octave is invariable, that of the sestet is free, (4) sonnets of miscellaneous structure

With regard to what is called the contemporary form, —a Petrarchan arrangement with the sestet divided very sharply from the octave,—the crowning difficulty and the crowning triumph of the sonnet writer has always been to so handle the rhythm of the prescribed structure as to make it seem in each individual sonnet the inevitable and natural rhythm demanded by the emotion which gives the individual sonnet birth, and thus can perhaps only be achieved when the richness and apparent complexity of the rhyme-arrangement is balanced by that perfect lucidity and simplicity of syntax which is the special quest of the "sonnet of flow and ebb"

The wave theory has found acceptance with most recent students of the sonnet, such as Rossetti and the late Mark Pattison, Mr J A Symonds, Mr Hall Caine, and Mr William Sharp. Mr Symonds, indeed, seems to hint that the very name given by the Italians to the two tercets, the volta or turn, indicates the metrical meaning of the form. "The striking metaphorical symbol," says he, "drawn from the observation of the swelling and declining wave can even in some examples be applied to sonnets on the Shakespearean model, for, as a wave may fall gradually or abruptly, so the sonnet may sink with stately volume or with precipitate subsidence to its close. Rossetti furnishes incomparable examples of the former and more desirable conclusion, Sydney Dobell, in *Home in Wan Time*, yields an extreme specimen of the latter"

And now as to the Shakespearean sonnet. Some very acute critics have spoken as if this form were merely a lawless succession of three quatrains clinched by a couplet, and as if the number of the quatrains might just as well have been two or four as the present prescribed number of three. If this were so, it would unquestionably be a serious impeachment of the Shakespearean sonnet, for save in the poetry of ingenuity no metric arrangement is otherwise than bad unless it be the result of a deep metrical necessity.

If the prescriptive arrangement of three quatrains clinched by a couplet is not a metrical necessity, if it is not demanded in order to prevent the couplet from losing its power, such an arrangement is idle and worse than idle, just as, in the case of the Petrarchan sonnet, if it can be shown that the solid unity of the outflowing wave can be maintained as completely upon three rhymes as upon two, then the restriction of the octave to two rhymes is simple pedantry. But he who would test the metrical necessity of the arrangement in the Shakespearean sonnet has only to make the experiment of writing a poem of two quatrains with a couplet, and then another poem of four quatrains with a couplet, in order to see how inevitable is the metrical necessity of the Shakespearean number and arrangement for the achievement of the metrical effect which Shakespeare, Drayton, and others sought. While in the poem of two quatrains the expected couplet has the sharp epigrammatic effect of the couplet in ordinary stanzas (such as that of *ottava rima*, and as that of the *Venus and Adonis* stanza), destroying that pensive sweetness which is the characteristic of the Shakespearean sonnet, the poem of four quatrains is just sufficiently long for the expected pleasure of the couplet to be dispersed and wasted.

The quest of the Shakespearean sonnet is not, like that of the sonnet of octave and sestet, sonority, and, so to speak, metrical counterpoint, but sweetness, and the sweetest of

all possible arrangements in English versification is a succession of decasyllabic quatrains in alternate rhymes knit together and clinched by a couplet—a couplet coming not so far from the initial verse as to lose its binding power, and yet not so near the initial verse that the ring of epigram disturbs the "linked sweetness long drawn out" of this movement, but sufficiently near to shed its influence over the poem back to the initial verse. A chief part of the pleasure of the Shakespearean sonnet is the expectation of the climacteric rest of the couplet at the end (just as a chief part of the pleasure of the sonnet of octave and sestet is the expectation of the answering ebb of the sestet when the close of the octave has been reached), and this expectation is gratified too early if it comes after two quatrains, while, if it comes after a greater number of quatrains than three, it is dispersed and wasted altogether.

The French sonnet has a regular Petrarchan octave with a sestet of three rhymes beginning with a couplet. The Spanish sonnet is also based on the pure Italian type, and is extremely graceful and airy. The same may be said of the Portuguese sonnet—a form of which the illustrious Camoens has left nearly three hundred examples. (T N)

SOPHIA DOROTHEA (1666–1726), the daughter and heiress of Duke George William of Brunswick-Lüneburg-Celle, was born on September 15, 1666. On November 21, 1682, she was married to Prince George Louis of Hanover, afterwards George I of England, to whom she bore in 1683 a son, afterwards King George II, and in 1687 a daughter, Sophia Dorothea, afterwards the wife of Frederick William I of Prussia and the mother of Frederick the Great. For her illicit relations with Count Philip Christopher von Königsmark (see vol x p 420) Sophia Dorothea was divorced from her husband the elector in December 1694, and the remainder of her life was spent in a dignified captivity under a military guard at her ancestral seat of Ahlden. She died on November 13, 1726. Her correspondence with Königsmark was discovered at Lund by Prof Palmblad, and published by him in 1847, see also the Count von Schulenburg's *Herzogin von Ahlden* (Leipzig, 1852).

SOPHISTS. Sophist, or "man of wisdom," was the name given by the Greeks about the middle of the 5th century B C to certain teachers of a superior grade who, distinguishing themselves from philosophers on the one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civic life. For nearly a hundred years the sophists held almost a monopoly of general or liberal education. Yet, within the limits of the profession, there was considerable diversity both of theory and of practice. Four principal varieties are distinguishable, and may be described as the sophistries of culture, of rhetoric, of politics, and of eristic or disputation. Each of these predominated in its turn, though not to the exclusion of others, the sophistry of culture beginning about 447, and leading to the sophistry of eristic, and the sophistry of rhetoric taking root in central Greece about 427, and merging in the sophistry of politics. Further, since Socrates and the Socratics were educators, they too might be, and in general were, regarded as sophists, but, as they conceived truth—so far as truth was attainable—rather than success in life, in the law court, in the assembly, or in debate, to be the right end of intellectual effort, they were at variance with their rivals, and are commonly ranked by historians, not with the sophists, who confessedly despaired of knowledge, but with the philosophers, who, however unavailingly, continued to seek it. With the establishment of the great philosophical schools—first, of

the Academy, next of the Lyceum—the philosophers took the place of the sophists as the educators of Greece

The sophistical movement was then primarily an attempt to provide a general or liberal education which should supplement the customary instruction in reading, writing, gymnastic, and music. But, as the sophists of the first period chose for their instruments grammar, style, literature, and oratory, while those of the second and third developments were professed rhetoricians, sophistry exercised an important influence upon literature. Then again, as the movement, taking its rise in the philosophical agnosticism which grew out of the early physical systems, was itself persistently sceptical, sophistry may be regarded as an interlude in the history of philosophy. Finally, the practice of rhetoric and eristic, which presently became prominent in sophistical teaching, had, or at any rate seemed to have, a mischievous effect upon conduct, and the charge of seeking, whether in exposition or in debate, not truth but victory—which charge was impressively urged against the sophists by Plato—grew into an accusation of holding and teaching immoral and unsocial doctrines, and in our own day has been the subject of eager controversy. In the present article the matters above indicated will be dealt with under the following heads—(1) the genesis and development of sophistry, (2) the relations of sophistry to education, literature, and philosophy, (3) the theory of Grotto

(1) *Genesis and Development of Sophistry*—Sophistry arose out of a crisis in philosophy. The earlier Ionian physicists, Thales, Anaximander, and Anaximenes,—in their attempts to trace the multiplicity of things to a single material element, had been troubled by no misgivings about the possibility of knowledge. But, when Heraclitus to the assumption of fire as the single material cause added the doctrine that all things are in perpetual flux, he found himself obliged to admit that things cannot be known. Thus, though, in so far as he asserted his fundamental doctrine without doubt or qualification, he was a dogmatist, in all else he was a sceptic. Again, the Eleatic Parmenides, deriving from the theologian Xenophanes the distinction between *επιστήμη* and *δόξα*, conceived that, whilst the One exists, and is the object of knowledge, the Multiplicity of things becomes, and is the object of opinion, but, when his successor Zeno provided the system with a logic, the consistent application of that logic resolved the fundamental doctrine into the single proposition "One is One," or, more exactly, into the single identity "One One." Thus Eleaticism, though professedly dogmatic, was inconsistent in its theory of the One and its attributes, and openly sceptical in regard to the world of nature. Lastly, the philosophers of the second physical succession,—Empedocles and Anaxagoras,—not directly attacking the great mystery of the One and the Many, but in virtue of a scientific instinct approaching it through the investigation of phenomena, were brought by their study of sensation to perceive and to proclaim the inadequacy of the organs of sense. Thus they too, despite their air of dogmatism, were in effect sceptics. In short, from different standpoints, the three philosophical successions had devised systems which were in reality sceptical, though they had none of them recognized the sceptical inference.

Towards the middle of the 5th century, however, Protagoras of Abdera, taking account of the teaching of the first, and possibly of the second, of the physical successions, and Gorgias of Leontini, starting from the teaching of the metaphysical succession of Elea, drew that sceptical inference from which the philosophers had shrunk. If, argued Protagoras in a treatise entitled *Truth*, all things are in flux, so that sensation is subjective, it

follows that "Man is the measure of all things, of what is, that it is, and of what is not, that it is not", in other words, there is no such thing as objective truth. Similarly, Gorgias, in a work *On Nature, or on the Nonent*, maintained (a) that nothing is, (b) that, if anything is, it cannot be known, (c) that, if anything is and can be known, it cannot be expressed in speech, and the summaries which have been preserved by Sextus Empiricus (*Adv. Math.*, vii 65–87) and by the author of the *De Melisso*, &c. (cc 5, 6), show that, in defending these propositions, Gorgias availed himself of the arguments which Zeno had used to discredit the popular belief in the existence of the Many, in other words, that Gorgias turned the destructive logic of Zeno against the constructive ontology of Parmenides, thereby not only reducing Eleaticism to nothingness, but also, until such time as a better logic than that of Zeno should be provided, precluding all philosophical inquiry whatsoever. Thus, whereas the representatives of the three successions had continued to regard themselves as philosophers or seekers after truth, Protagoras and Gorgias, plainly acknowledging their defeat, withdrew from the ungrateful struggle.

Meagre as were the results which the earlier thinkers had obtained, the extinction of philosophy just at the time when the liberal arts became more technical, and consequently less available as employments of leisure, threatened to leave a blank in Hellenic life. Accordingly Protagoras, while with the one hand he put away philosophy, with the other offered a substitute. Emphasizing the function of the teacher, which with the philosophers had been subordinate, and proclaiming the right end of intellectual endeavour to be, not "truth" (*ἀλήθεια*) or "wisdom" (*σοφία*), which was unattainable, but "virtue" or "excellence" (*ἀρετή*), he sought to communicate, not a theory of the universe, but an aptitude for civic life. "The lesson which I have to teach," Plato makes him say (*Prot.*, 318 E), "is prudence or good counsel, both in respect of domestic matters, that the man may manage his household aright, and in respect of public affairs, that he may be thoroughly qualified to take part, both by deed and by word, in the business of the state. In other words, I profess to make men good citizens." As instruments of education Protagoras used grammar, style, poetry, and oratory. Thus, whereas hitherto the young Greek, having completed his elementary training in the schools of the *γραμματιστής*, the *κισιριστής*, and the *ραδιοπίβης*, was left to prepare himself for his life's work as best he might, by philosophical speculation, by artistic practice, or otherwise, one who passed from the elementary schools to the lecture room of Protagoras received from him a "higher education." The programme was exclusively literary, but for the moment it enabled Protagoras to satisfy the demand which he had discovered and evoked. Wherever he went, his lecture room was crowded with admiring pupils, whose homage filled his purse and enhanced his reputation.

After Protagoras the most prominent of the literary sophists was Prodicus of Ceos. Establishing himself at Athens, he taught "virtue" or "excellence," in the sense attached to the word by Protagoras, partly by means of literary subjects, partly in discourses upon practical ethics. It is plain that Prodicus was an affected pedant. Yet his simple conventional morality found favour, and Plato (*Rep.*, 600 C) couples him with Protagoras in his testimony to the popularity of the sophists and their teaching.

At Athens, the centre of the intellectual life of Greece, there was soon to be found a host of sophists, some of them strangers, others citizens, some of them bred under Protagoras and Prodicus, others self-taught. In the teaching of the sophists of this younger generation

two points are observable. First, their independence of philosophy and the arts being assured, though they continued to regard "civic excellence" as their aim, it was no longer necessary for them to make the assertion of its claims a principal element in their exposition. Secondly, for the sake of novelty they extended their range, including scientific and technical subjects, but handling them, and teaching their pupils to handle them, in a popular way. In this stage of sophistry then, the sophist, though not a specialist, trenched upon the provinces of specialists, and accordingly Plato (*Prot.*, 318 E) makes Protagoras pointedly refer to sophists who, "when young men have made their escape from the arts, plunge them once more into technical study, and teach them such subjects as arithmetic, astronomy, geometry, and music." The sophist of whom the Platonic Protagoras is here thinking was Hippias of Elis, who gave popular lectures, not only upon the four subjects just mentioned, but also upon grammar, mythology, family history, archaeology, Homerology, and the education of youth. In this polymath we see at once the degradation of the sophistry of culture and the link which connects Protagoras and Prodicus with the eristics, who at a later period taught, not, like Hippias, all branches of learning, but a universally applicable method of disputation.

Meanwhile, Gorgias of Leontini, who, as has been seen, had studied and rejected the philosophy of western Greece, gave to sophistry a new direction by bringing to the mother country the technical study of rhetoric,—especially forensic rhetoric (Plato, *Gorg.*, 454 B, cf. Aristotle, *Rhet.*, 1354 b 26),—which study had begun in Sicily with Corax and Tisias nearly forty years before. Gorgias was already advanced in years and rich in honours when, in 427, he visited Athens as the head of an embassy sent to solicit aid against Syracuse. Received with acclamation, he spent the rest of his long life in central Greece, winning applause by the display of his oratorical gifts and acquiring wealth by the teaching of rhetoric. There is no evidence to show that at any period of his life he called himself a sophist, and, as Plato (*Gorg.*, 449 A) makes him describe himself as a *πρῶτος*, it is reasonable to suppose that he preferred that title. That he should do so was only natural, since his position as a teacher of rhetoric was already secure when Protagoras made his first appearance in the character of a sophist, and, as Protagoras, Prodicus, and the rest of the sophists of culture offered a comprehensive education, of which oratory formed only a part, whilst Gorgias made no pretence of teaching "civic excellence" (Plato, *Meno.*, 95 C), and found a substitute for philosophy, not in literature generally, but in the professional study of rhetoric alone, it would have been convenient if the distinction between sophistry and rhetoric had been maintained. But, though, as will be seen hereafter, these two sorts of education were sometimes distinguished, Gorgias and those who succeeded him as teachers of rhetoric, such as Thrasymachus of Chalcedon and Polus of Agrigentum, were commonly called by the title which Protagoras had assumed and brought into familiar use.

Rhetorical sophistry, as taught by Gorgias with special reference to the requirements of the law courts, led by an easy transition to political sophistry. During the century which had elapsed since the expulsion of the Pisistratids and the establishment of the democracy, the Athenian constitution had developed with a rapidity which produced an oligarchical reaction, and the discussion of constitutional principles and precedents, always familiar to the citizen of Athens, was thus abnormally stimulated. The Peloponnesian War too not only added a deeper interest to ordinary questions of policy, but also caused the

relations of dissentient parties, of allied and belligerent states, of citizens and aliens, of bond and free, of Greeks and barbarians, to be eagerly debated in the light of present experience. It was only natural then that some of those who professed to prepare young Athenians for public life should give to their teaching a distinctively political direction, and accordingly we find Isocrates recognizing teachers of politics and discriminating them at once from those earlier sophists who gave popular instruction in the arts and from the contemporary eristics. To this class, that of the political sophists, may be assigned Lycophrone, Alcidas, and Isocrates himself. For, though that celebrated personage would have liked to be called, not "sophist," but "political philosopher," and tried to fasten the name of "sophist" upon his opponents the Socratics, it is clear from his own statement that he was commonly ranked with the sophists, and that he had no claim, except on the score of superior popularity and success, to be dissociated from the other teachers of political rhetoric. It is true that he was not a political sophist of the vulgar type, that as a theorist he was honest and patriotic, and that, in addition to his fame as a teacher, he had a distinct reputation as a man of letters, but he was a professor of political rhetoric, and, as such, in the phraseology of the day, a sophist. He had already reached the height of his fame when Plato opened a rival school at the Academy, and pointedly attacked him in the *Gorgias*, the *Phædrus*, and the *Republic*. Thenceforward there was a perpetual controversy between the rhetorician and the philosopher, and the struggle of educational systems continued until, in the next generation, the philosophers were left in possession of the field.

While the sophistry of rhetoric led to the sophistry of politics, the sophistry of culture led to the sophistry of disputation. It has been seen that the range of subjects recognized by Protagoras and Prodicus gradually extended itself, until Hippias professed himself a teacher of all branches of learning, including in his list subjects taught by artists and professional men, but handling them from a popular or non professional point of view. The successors of the polymath claimed to possess and to communicate, not the knowledge of all branches of learning, but an aptitude for dealing with all subjects, which aptitude should make the knowledge of any subject superfluous. In other words, they cultivated skill in disputation. Now skill in disputation is plainly a valuable accomplishment, and, as the Aristotelian logic grew out of the regulated discussions of the eristics and their pupils, the disputant sophistry of the 4th century deserves more attention and more respect than it usually receives from historians of Greek thought. But when men set themselves to cultivate skill in disputation, irrespective of the matter debated,—when men regard the matter discussed, not as a serious issue, but as a thesis upon which to practise their powers of controversy,—they learn to pursue, not truth, but victory, and, their criterion of excellence having been thus perverted, they presently prefer ingenious fallacy to solid reasoning, and the applause of bystanders to the consciousness of honest effort. Indeed, the sophists generally had a predisposition to error of this sort, not only because sophistry was from the beginning a substitute for the pursuit of truth, but also because the successful professor, travelling from city to city, or settling abroad, could take no part in public affairs, and thus was not at every step reminded of the importance of the "material" element of exposition and reasoning. Paradox, however, soon becomes stale, and fallacy wearisome. Hence, despite its original popularity, eristical sophistry could not hold its ground. The man of the world who had cultivated it in his youth regarded it in ripe years as a

foolish pedantry, or at best as a propædæutic exercise, while the serious student, necessarily preferring that form of disputation which recognized truth as the end of this as of other intellectual processes, betook himself to one or other of the philosophies of the revival.

In order to complete this sketch of the development of sophistry in the latter half of the 5th century and the earlier half of the 4th, it is necessary next to take account of Socrates and the Socratics. A foe to philosophy and a renegade from art, Socrates took his departure from the same point as Protagoras, and moved in the same direction, that of the education of youth. Finding in the cultivation of "virtue" or "excellence" a substitute for the pursuit of scientific truth, and in disputation the sole means by which "virtue" or "excellence" could be attained, he resembled at once the sophists of culture and the sophists of eristic. But, inasmuch as the "virtue" or "excellence" which he sought was that of the man rather than that of the official, while the disputation which he practised had for its aim, not victory, but the elimination of error, the differences which separated him from the sophists of culture and the sophists of eristic were only less considerable than the resemblances which he bore to both, and further, though his whole time and attention were bestowed upon the education of young Athenians, his theory of the relations of teacher and pupil differed from that of the recognized professors of education, inasmuch as the taking of fees seemed to him to entail a base surrender of the teacher's independence. The principal characteristics of Socrates's theory of education were accepted, *mutatis mutandis*, by the leading Socratics. With these resemblances to the contemporary professors of education, and with these differences, were Socrates and the Socratics sophists or not? To this question there is no simple answer, yes or no. It is certain that Socrates's contemporaries regarded him as a sophist, and it was only reasonable that they should so regard him, because in opposition to the physicists of the past and the artists of the present he asserted the claims of higher education. But, though according to the phraseology of the time he was a sophist, he was not a typical sophist,—his principle that, while scientific truth is unattainable by man, right opinion is the only basis of right action, clearly differentiating him from all the other professors of "virtue." Again, as the Socratics—Plato himself, when he established himself at the Academy, being no exception—were, like their master, educators rather than philosophers, and in their teaching laid especial stress upon discussion, they too were doubtless regarded as sophists, not by Isocrates only, but by their contemporaries in general, and it may be conjectured that the disputatious tendencies of the Megarian school made it all the more difficult for Plato and others to secure a proper appreciation of the difference between dialectic, or discussion with a view to the discovery of truth, and eristic, or discussion with a view to victory. Changing circumstances, however, carry with them changes in the meaning and application of words. Whereas, so long as philosophy was in abeyance Socrates and the Socratics were regarded as sophists of an abnormal sort, as soon as philosophy revived it was dimly perceived that, in so far as Socrates and the Socratics dissented from sophistry, they preserved the philosophical tradition. This being so, it was found convenient to revise the terminology of the past, and to include in the philosophical succession those who, though not philosophers, had cherished the sacred spark. As for Socrates, he ranked himself neither with the philosophers, who professed to know, nor with the sophists, who professed to teach, and, if he sometimes described himself as a φιλόσοφος, he was careful to indicate that he pretended to no other knowledge than that of his own limitations.

It would seem then, (1) that popular nomenclature included under the term "sophist" all teachers—whether professors, or, like Socrates, amateurs—who communicated, not artistic skill, nor philosophical theory, but a general or liberal education, (2) that, of those who were commonly accounted sophists, some professed culture, some forensic rhetoric, some political rhetoric, some oristic, some (i.e., the Socratics) dialectic, (3) that the differences between the different groups of sophists were not inconsiderable, and that in particular the teaching of the rhetoricians was distinct in origin, and, in so far as its aim was success in a special walk of life, distinct in character, from the more general teaching of the sophists of culture, the eristics, and the dialecticians, while the teaching of the dialecticians was discriminated from that of the rest, in so far as the aim of the dialecticians was truth, or at least the bettering of opinion, and, consequently, (4) that, in awarding praise and blame to sophistry and its representatives, the distinctive characteristics of the groups above enumerated must be studiously kept in view.

Lapso of time and change of circumstances brought with them, not merely changes in the subjects taught, but also changes in the popular estimate of sophistry and sophists. The first and most obvious sentiment which sophistry evoked was an enthusiastic and admiring interest. The sophist seemed to his youthful hearers to open a new field of intellectual activity and thereby to add a fresh zest to existence. But in proportion to the fascination which he exercised upon the young was the distrust which he inspired in their less pliable elders. Not only were they dismayed by the novelty of the sophistical teaching, but also they vaguely perceived that it was subversive of authority, of the authority of the parent over the child as well as of the authority of the state over the citizen. Of the two conflicting sentiments, the favour of the young, gaining as years passed away, naturally prevailed, sophistry ceased to be novel, and attendance in the lecture rooms of the sophists came to be thought not less necessary for the youth than attendance in the elementary schools for the boy. The lively enthusiasm and the furious opposition which greeted Protagoras had now burnt themselves out, and before long the sophist was treated by the man of the world as a harmless, necessary pedagogue.

That sophistry must be studied in its historical development was clearly seen by Plato, whose dialogue called the *Sophist* contains a formal review of the changing phases and aspects of sophistical teaching. The subject which is discussed in that dialogue and its successor the *Statesman* being the question "Are sophist, statesman, and philosopher identical or different?" the Eleate who acts as protagonist seeks a definition of the term "sophist" by means of a series of divisions or dichotomies. In this way he is led to regard the sophist successively—(1) as a practitioner of that branch of mercenary persuasion in private which professes to impart "virtue" and exacts payment in the shape of a fee, in opposition to the flatterer who offers pleasure, asking for sustenance in return, (2) as a practitioner of that branch of mental trading which purveys from city to city discourses and lessons about "virtue," in opposition to the artist who similarly purveys discourses and lessons about the arts, (3) and (4) as a practitioner of those branches of mental trading, retail and wholesale, which purvey discourses and lessons about "virtue" within a city, in opposition to the artists who similarly purvey discourses and lessons about the arts, (5) as a practitioner of that branch of eristic which brings to the professor pecuniary emolument, eristic being the systematic form of antilogic, and dealing with justice, injustice, and other abstractions, and antilogic being that form of disputation which uses question and answer in private, in opposition to forensic, which uses continuous discourse in the law-courts, (6) as a practitioner of that branch of education which purges away the vain conceit of wisdom by means of cross examination, in opposition to the traditional method of reproof or admonition. These definitions being thus various, the Eleate notes that the sophist, in consideration of a fee, disputes, and teaches others to dispute, about things divine, cosmical, metaphysical, legal, political, technical,—in fact, about everything,

—not having knowledge of them, because universal knowledge is unattainable, after which he is in a position to define the sophist (7) as a conscious impostor who, in private, by discontinuous discourse, compels his interlocutor to contradict himself, in opposition to the *δημοσολογιστής*, who, in public, by continuous discourse, imposes upon crowds.

It is clear that the final definition is preferred, not because of any intrinsic superiority, but because it has a direct bearing upon the question "Are sophist, statesman, and philosopher identical or different?" and that the various definitions represent different stages or forms of sophistry as conceived from different points of view. Thus the first and second definitions represent the founders of the sophistry of culture, Protagoras and Prodicus, from the respective points of view of the older Athenians, who disliked the new culture, and the younger Athenians, who admired it, the third and fourth definitions represent imitators to whom the note of itinerancy was not applicable, the fifth definition represents the earlier eristics, contemporaries of Socrates, whom it was necessary to distinguish from the teachers of forensic oratory, the sixth is framed to meet the anomalous case of Socrates, in whom many saw the typical sophist, though Plato conceives this view to be unfortunate, and the seventh and final definition, having in view eristical sophistry fully developed, distinguishes it from *δημοσολογική*, i.e., political rhetoric, but at the same time hints that, though *σοφιστική* and *δημοσολογική* may be discriminated, they are nevertheless near akin, the one being the ape of philosophy, the other the ape of statesmanship. In short, Plato traces the changes which, in less than a century, had taken place in the meaning of the term, partly through changes in the practice of the sophists, partly through changes in their surroundings and in public opinion, so as to show by a familiar instance that general terms which do not describe natural kinds cannot have a stable connotation.

Now it is easy to see that in this careful statement Plato recognizes three periods. The first four definitions represent the period of Protagoras, Prodicus, and their immediate successors, when the object sought was "virtue," "excellence," "culture," and the means to it was literature. The fifth and sixth definitions represent the close of the 5th century, when sophistry handled eristically, and perhaps, though Plato demurs to the inclusion, dialectically, questions of justice, injustice, and the like, *δικαιική* or forensic rhetoric being its proximate rival. The seventh definition represents the first half of the 4th century, when sophistry was eristical in a wider field, having for its rival, not forensic rhetoric, but the rhetoric of the assembly. Plato's classification of educational theories is then substantially the classification adopted in this article, though, whereas here, in accordance with well attested popular usage, all the educational theories mentioned are included under the head of sophistry, Plato allows to rhetoric, forensic and political, an independent position, and hints that there are grounds for denying the title of sophist to the dialectician Socrates. Incidentally we gather two important facts,—(1) that contemporary with the dialectic of Socrates there was an eristic, and (2) that this eristic was mainly applied to ethical questions. Finally, we may be sure that, if Plato was thus careful to distinguish the phases and aspects of sophistical development, he could never have fallen into the modern error of bestowing upon those whom the Greeks called sophists either indiscriminate censure or indiscriminate laudation.

(2) *Relations of Sophistry to Education, Literature, and Philosophy*—If then the sophists, from Protagoras to Isocrates, were before everything educators, it becomes necessary to inquire whether their labours marked or promoted an advance in educational theory and method. At the beginning of the 5th century B.C. every young Greek of the better sort already received indumentary instruction, not only in music and gymnastics, but also in reading and writing. Further, in the colonies, and especially the colonies of the West, philosophy and art had done something for higher education. Thus in Italy the Pythagorean school was, in the fullest sense of the term, an educational institution, and in Sicily the rhetorical teaching of Corax and Tisias was presumably educational in the same sense as the teaching of Gorgias. But in central Greece, where, at any rate down to the Persian Wars, politics, domestic and foreign, were all engrossing, and left the citizen little leisure for self-cultivation, the need of a higher education had hardly made itself felt. The overthrow of the Persian invaders changed all this. Henceforward the best of Greek art, philosophy, and literature gravitated to Athens, and with their concentration and consequent development came a general and

growing demand for teaching. As has been seen, it was just at this period that philosophy and art ceased to be available for educational purposes, and accordingly the literary sophists were popular precisely because they offered advanced teaching which was neither philosophical nor artistic. Their recognition of the demand and their attempt to satisfy it are no small claims to distinction. That, whereas before the time of Protagoras there was little systematic education in the colonies and less in central Greece, after his time attendance in the lecture-rooms of the sophists was the customary sequel to attendance in the elementary schools, is a fact which speaks for itself.

But this is not all. The education provided by the sophists of culture had positive merits. When Protagoras included in his course grammar, style, interpretation of the poets, and oratory, supplementing his own continuous expositions by disputations in which he and his pupils took part, he showed a not inadequate appreciation of the requisites of a literary education, and it may be conjectured that his comprehensive programme, which Prodicus and others extended, had something to do with the development of that versatility which was the most notable element in the Athenian character.

There is less to be said for the teachers of rhetoric, politics, and eristic, who, in limiting themselves each to a single subject,—the rhetoricians proper or forensic rhetoricians to one branch of oratory, the politicians or political rhetoricians to another, and the eristics to disputation,—ceased to be educators and became instructors. Nevertheless, rhetoric and disputation, though at the present day strangely neglected in English schools and universities, are, within their limits, valuable instruments, and, as specialization in teaching does not necessarily imply specialization in learning, many of those who attended the lectures and the classes of a rhetorician or an eristic sought and found other instruction elsewhere. It would seem then that even in its decline sophistry had its educational use. But in any case it may be claimed for its professors that in the course of a century they discovered and turned to account most of the instruments of literary education.

With these considerable merits, normal sophistry had one defect, its indifference to truth. Despairing of philosophy,—that is to say, of physical science,—the sophists were prepared to go all lengths in scepticism. Accordingly the epideictic sophists in exposition, and the argumentative sophists in debate, one and all, studied, not matter but style, not accuracy but effect, not proof but persuasion. In short, in their hostility to science they refused to handle literature in a scientific spirit. That this defect was serious was dimly apprehended even by those who frequented and admired the lectures of the earlier sophists, that it was fatal was clearly seen by Socrates, who, himself commonly regarded as a sophist, emphatically reprehended, not only the taking of fees, which was after all a mere incident, objectionable because it seemed to preclude independence of thought, but also the fundamental disregard of truth which infected every part and every phase of sophistical teaching. To these contemporary censures the modern critic cannot refuse his assent.

To literature and to oratory the sophists rendered good service. Themselves of necessity stylists, because their professional success largely depended upon skilful and effective exposition, the sophists both of culture and of rhetoric were professedly teachers of the rules of grammar and the principles of written and spoken discourse. Thus, by example as well as by precept, they not only taught their hearers to value literary and oratorical excellence,

but also took the lead in fashioning the style of their time. Their influence in these respects was weighty and important. Whereas when sophistry began prose composition was hardly practised in central Greece, the sophists were still the leaders in literature and oratory when Plato wrote the *Republic*, and they had hardly lost their position when Demosthenes delivered the *Philippics*. In fact, it is not too much to say that it was the sophists who provided those great masters with their consummate instrument, and it detracts but little from the merit of the makers if they were themselves unable to draw from it its finer tones.

The relation of sophistry to philosophy was throughout one of pronounced hostility. From the days of Protagoras, when this hostility was triumphant and contemptuous, to the days of Isocrates, when it was jealous and bitter, the sophists were declared and consistent sceptics. But, although Protagoras and Gorgias had examined the teaching of their predecessors so far as to satisfy themselves of its futility and to draw the sceptical inference, their study of the great problem of the day was preliminary to their sophistry rather than a part of it, and, as the overthrow of philosophy was complete and the attractions of sophistry were all-powerful, the question, "What is knowledge?" ceased for a time to claim or to receive attention. There is then no such thing as a "sophistical theory of knowledge." Similarly, the recognition of a "sophistical ethic" is, to say the least, misleading. It may have been that the sophists' preference of seeming to reality, of success to truth, had a mischievous effect upon the morality of the time, but it is clear that they had no common theory of ethics, and there is no warrant for the assumption that a sophist, as such, specially interested himself in ethical questions. When Protagoras asserted "civic excellence" or "virtue" to be the end of education, he neither expressed nor implied a theory of morality. Prodicus in his platitudes reflected the customary morality of the time. Gorgias said plainly that he did not teach "virtue." If Hippias, Polus, and Thrasymachus defied conventional morality, they did so independently of one another, and in this, as in other matters, they were disputants maintaining paradoxical theses, rather than thinkers announcing heretical convictions. The morality of Isocrates bore a certain resemblance to that of Socrates. In short, the attitude of the sophists towards inquiry in general precluded them, collectively and individually, from attachment to any particular theory. Yet among the so-called sophists there were two who had philosophical leanings, as appears in their willingness to be called by the title of philosopher. First, Socrates, whilst he conceived that the physicists had mistaken the field of inquiry, absolute truth being unattainable, maintained, as has been seen, that one opinion was better than another, and that consistency of opinion, resulting in consistency of action, was the end which the human intellect properly proposes to itself. Hence, though an agnostic, he was not unwilling to be called a philosopher, in so far as he pursued such truth as was attainable by man. Secondly, when sophistry had begun to fall into contempt, the political rhetorician Isocrates claimed for himself the time honoured designation of philosopher, "herein," says Plato, "resembling some tinker, bald pated and short of stature, who, having made money, knocks off his chains, goes to the bath, buys a new suit, and then takes advantage of the poverty and desolation of his master's daughter to urge upon her his odious addresses" (*Rep.*, 11 495 E). It will be seen, however, that neither Socrates nor Isocrates was philosopher in any strict sense of the word, the speculative aims of physicists and metaphysicians being foreign to the practical theories both of the one and of the other.

As for the classification of sophistical methods, so for their criticism, the testimony of Plato is all important. It may be conjectured that, when he emerged from the purely Socratic phase of his earlier years, Plato gave himself to the study of contemporary methods of education and to the elaboration of an educational system of his own, and that it was in this way that he came to the metaphysical speculations of his maturity. It may be imagined further that, when he established himself at the Academy, his first care was to draw up a scheme of education, including arithmetic, geometry (plane and solid), astronomy, harmonics, and dialectic, and that it was not until he had arranged for the carrying out of this programme that he devoted himself to the special functions of professor of philosophy. However this may be, we find amongst his writings,—intermediate, as it would seem, between the Socratic conversations of his first period of literary activity and the metaphysical disquisitions of a later time,—a series of dialogues which, however varied their ostensible subjects, agree in having a direct bearing upon education. Thus the *Protagoras* brings the educational theory of Protagoras and the sophists of culture face to face with the educational theory of Socrates, so as to expose the limitations of both; the *Gorgias* deals with the moral aspect of the teachings of the forensic rhetorician Gorgias and the political rhetorician Isocrates, and the intellectual aspect of their respective theories of education is handled in the *Phaedrus*, the *Meno* on the one hand exhibits the strength and the weakness of the teaching of Socrates, and on the other brings into view the makeshift method of those who, despising systematic teaching, regarded the practical politician as the true educator, the *Euthydemus* has for its subject the eristical method, finally, having in these dialogues characterized the current theories of education, Plato proceeds in the *Republic* to develop an original scheme. Plato's criticisms of the sophists are then, in the opinion of the present writer, no mere *obiter dicta*, introduced for purposes of literary adornment or dramatic effect, but rather the expressions of profound and reasoned conviction, and, as such, entitled at any rate to respect. For the details of Plato's critique, the reader should go, not to the summaries of commentators, but to the dialogues themselves. In this place it is sufficient to say that, while Plato accredits no education satisfactory which has not knowledge for its basis, he emphatically prefers the scepticism of Socrates, which, despairing of knowledge, seeks right opinion, to the scepticism of the sophists, which, despairing of knowledge, abandons the attempt to better existing beliefs.

(3) *The Theory of Grote*—The post Platonic historians and critics, who, while they knew the earlier sophistry only through tradition, were eye witnesses of the sophistry of the decadence, were more alive to the faults than to the virtues of the movement. Overlooking the differences which separated the humanists from the eristics, and both of these from the rhetoricians, and taking no account of Socrates, whom they regarded as a philosopher, they forgot the services which Protagoras and Prodicus, Gorgias and Isocrates, had rendered to education and to literature, and included the whole profession in an indiscriminate and contemptuous censure. This prejudice, establishing itself in familiar speech, has descended from antiquity to modern times, colouring, when it does not distort, the narratives of biographers and the criticisms of commentators. "The sophists," says Grote, "are spoken of as a new class of men, or sometimes in language which implies a new doctrinal sect or school, as if they then sprang up in Greece for the first time—ostentatious impostors, flattering and duping the rich youth for their own personal gain, undermining the morality of Athens, public and private, and encouraging their pupils to the unscrupulous prosecution of ambition and cupidity. They are even affirmed to have succeeded in corrupting the general morality, so that Athens had become miserably degenerated and vicious in the latter years of the Peloponnesian War, as compared with what she was in the time of Miltiades and Aristides," and, although amongst the pre-Grotian scholars there were some who saw as clearly as Grote himself that "the sophists are a much-calumniated race" (G. H. Lewes), it is certain that historians of philosophy, and editors of Plato, especially the "acumen plumbeum Stallbaum," had given ample occasion for the energetic protest contained in the famous sixty-seventh chapter of Grote's *History of Greece*. Amongst the many merits of that admirable

scholar, it is one of the greatest that he has laid "the fiend called *die Sophistik*," that is to say, the theory that sophistry was an organized conspiracy against law and morals. Nevertheless, in this matter he is always an advocate, and it may be thought that, while he successfully disposes of the current slander, his description of his clients needs correction in some important particulars. Hence the following paragraphs, while they will resume and affirm his principal results, will qualify and impregnate some of his positions.

In so far as he is critical, Grote leaves little to be desired. That the persons styled sophists "were not a sect or school, with common doctrines or method," is clear. Common doctrine, that is to say, common doctrine of a positive sort, they could not have, because, being sceptics, they had nothing which could be called positive doctrine, while there was a period when even their scepticism was in no wise distinctive, because they shared it with all or nearly all their contemporaries. Neither were they united by a common educational method, the end and the instruments of education being diversely conceived by Protagoras, Gorgias, and Isocrates, to say nothing of the wider differences which separate these three from the eristics, and all the four normal types from the abnormal type represented by Socrates.

Again, it is certain that the theoretical and practical morality of the sophists, regarded as a class, was "neither above nor below the standard of the age." The taking of fees, the pride of professional success, and the teaching of rhetoric are no proofs either of conscious charlatanism or of ingrained depravity. Indeed, we have evidence of sound, if conventional, principle in Prodicus's apologue of the "Choice of Heracles," and of honourable, though eccentric, practice in the story of Protagoras's treatment of defaulting pupils. But, above all, it is antecedently certain that defection from the ordinary standard of morality would have precluded the success which the sophists unquestionably sought and won. In fact, public opinion made the morality of the sophists, rather than the sophists the morality of public opinion. Hence, even if we demur to the judgment of Grote that "Athens at the close of the Peloponnesian War was not more corrupt than Athens in the days of Miltiades and Aristides," we shall not "consider the sophists as the corruptors of Athenian morality," but rather with Plato lay the blame upon society itself, which, "in popular meetings, law courts, theatres, armies, and other great gatherings, with uproarious applause and clamorous applause" (*Rep.*, vi 492), educates young and old, and fashions them according to its pleasure.

Nor can we regard "Plato and his followers as the authorized teachers of the Greek nation and the sophists as the dissenters." On the contrary, the sophists were in quiet possession of the field when Plato, returning to Athens, opened the rival school of the Academy, and, while their teaching in all respects accommodated itself to current opinion, his, in many matters, ran directly counter to it.

But if thus far Grote's protest against prevalent assumptions carries an immediate and unhesitating conviction, it may be doubted whether his positive statement can be accounted final. "The appearance of the sophists," he says, "was no new fact." The paid teachers—whom modern writers set down as the sophists, and denounce as the modern pestilence of their age—were not distinguished in any marked or generic way from their predecessors. Now it is true that before 447 B.C., besides the teachers of writing, gymnastic, and music, to whom the young Greek resorted for elementary instruction, there were artists and artisans who not only practised

their crafts but also communicated them to apprentices and pupils, and that accordingly the Platonic Protagoras recognizes in the gymnast Iccus, the physician Herodicus, and the musicians Agathocles and Pythochides forerunners of the sophists. But the forerunners of the sophists are not to be confounded with the sophists themselves, and the difference between them is not far to seek. Though some of those who resorted to the teachers of rudiments and the artists derived from them such substitute for "higher education" as was before 447 generally obtainable, it was only incidentally that the teachers of rudiments and the artists communicated anything which could be called by that name. Contrariwise, the sophists were always and essentially professors of the higher education, and, although in process of time specialization assimilated sophistry to the arts, at the outset at any rate, its declared aim—the cultivation of the civic character—sufficiently distinguished sophistical education both from rudimentary instruction and from artistic training. It is true too that in some of the colonies philosophy had busied itself with higher education, but here again the forerunners of the sophists are easily distinguished from the sophists, since the sophists condemned, not only the scientific speculations of their predecessors, but also their philosophical aims, and offered to the Greek world a new employment for leisure, a new intellectual ambition.

Nor is it altogether correct to say that "the persons styled sophists had no principles common to them all and distinguishing them from others." Various as were the phases through which sophistry passed between the middle of the 5th century and the middle of the 4th, the sophists—Socrates himself being no exception—had in their declared antagonism to philosophy a common characteristic, and, if in the interval, philosophical speculation being temporarily suspended, scepticism ceased for the time to be peculiar, at the outset, when Protagoras and Gorgias broke with the physicists, and in the sequel, when Plato raised the cry of "back to Parmenides," this common characteristic was distinctive.

Further, it may be doubted whether Grote is sufficiently careful to distinguish between the charges brought against the sophists personally and the criticism of their educational methods. When the sophists are represented as conscious impostors who "poisoned and demoralized by corrupt teaching the Athenian moral character," he has, as has been seen, an easy and complete reply. But the question still remains—Was the education provided by Protagoras, by Gorgias, by Isocrates, by the eristics, and by Socrates good, bad, or indifferent? And, though the modern critic will not be prepared with Plato to deny the name of education to all teaching which is not based upon an ontology, it may nevertheless be thought that normal sophistry—as opposed to the sophistry of Socrates—was in various degrees unsatisfactory, in so far as it tacitly or confessedly ignored the "material" element of exposition or reasoning.

And if Grote overlooks important agreements he seems also to understate important differences. Regarding Protagoras, Gorgias, and Isocrates as types of one and the same sophistry (pp 487, 493, 495, 499, 544, 2d edition), and neglecting as slander or exaggeration all the evidence in regard to the sophistry of eristic (p 540), he conceives that the sophists undertook "to educate young men so as to make them better qualified for statesmen or ministers," and that "that which stood most prominent in the teaching of Gorgias and the other sophists was, that they cultivated and improved the powers of public speaking in their pupils." Excellent as a statement of the aim and method of Isocrates, and tolerable as a statement of those of Gorgias, these phrases are inexact if applied to

Protagoras, who, making "civic virtue" his aim, regarded statesmanship and administration as parts of "civic virtue," and consequently assigned to oratory no more than a subordinate place in his programme, while to the eristics—whose existence is attested, not only by Plato, but also by Isocrates and Aristotle—and to Socrates—whom Grote himself accounts a sophist—the description is plainly and palpably inappropriate.

Grote's note about the eristical sophists is perhaps the least satisfactory part of his exposition. That "there were in Athens persons who abused the dialectical exercise for frivolous puzzles" he admits, but "to treat Euthydemus and Dionysodorus as samples of 'The Sophists' is," he continues, "altogether unwarrantable." It would seem then that, while he regards rhetoric as the function of normal sophistry, taking indifferently as his types Protagoras, Gorgias, and Isocrates, he accounts Euthydemus and Dionysodorus (together with Socrates) as sophists, but as sophists of an abnormal sort, who may therefore be neglected. Now this view is inconsistent with the evidence of Plato, who, in the *Sophist*, in his final and operative definition, gives prominence to the eristical element, and plainly accounts it the main characteristic, not indeed of the sophistry of the 5th century, but of the sophistry of the 4th. It must be presumed then that, in virtue of his general suspicions of the Platonic testimony, Grote in this matter leaves the *Sophist* out of account. There is, however, another theory of the significance of Plato's allusions to eristical sophistry, that of Prof. H. Sidgwick, whose brilliant defence of Grote is an indispensable supplement to the original document. Giving a hearty general assent to Grote's theory, Sidgwick nevertheless introduces qualifications similar to some of those which are suggested in this article. In particular he allows that "there was at any rate enough of charlatanism in Protagoras and Hippias to prevent any ardour for their historical reputation," that the sophists generally "had in their lifetime more success than they deserved," that it was "antagonism to their teaching which developed the genius of Socrates," and, above all, that, "in his anxiety to do justice to the *Sophist*, Grote laid more stress than is at all necessary on the partisanship of Plato." Now this last admission precludes Sidgwick from neglecting, as Grote had done, the evidence of the *Euthydemus*. Pointing out that the sophists of that dialogue "profess εἰς ἀπὸρρίαν ἐπιμελείαν προσηφίας by means of dialogue," that "they challenge the interlocutor νῆξεν λόγον," that "their examples are drawn from common objects and vulgar trades," that "they maintain positions that no known to have been held by Megarians and Cynics," he infers that "what we have here presented to us as 'sophistic' is neither more nor less than a caricature of the Megarian logic," and further, on the ground that "the whole conception of Socrates and his effect on his contemporaries, as all authorities combine to represent it, requires us to assume that his manner of discourse was quite novel, that no one before had systematically attempted to show men their ignorance of what they believed themselves to know," he is "disposed to think that the art of disputation which is ascribed to sophists in the *Euthydemus* and the *Sophistes* (and exhaustively analysed by Aristotle in the *μετὰ Σοφιστικῶν Ελέγχων*) originated entirely with Socrates, and that he is altogether responsible for the form at least of this second species of sophistry." To this theory the present writer is unable to subscribe. That Plato was not careful to distinguish the Megarians and the Cynics from the eristical sophists, and that the disputants of the 4th century affected some of the mannerisms of the greatest disputant of the 5th century, he willingly concedes. But he cannot allow either that the Megarians and the Cynics were the only eristics, or that eristical sophistry began with Socrates. Plainly this is not the place for a full examination of the question, yet it may be remarked—(1) that the previous history of the sophists of the *Euthydemus*, who had been professors of tactics (Xenophon, *Mem.*, iii. 1, 1), swordsmanship, and forensic argumentation, implies that they came to eristic, not from the sophistry of Socrates, but from that of the later humanists, polymaths of the type of Hippias, (2) that the fifth and sixth definitions of the *Sophist*, in which "that branch of eristic which brings pecuniary gain to the practitioner" is opposed to the "patience-trying, purgative elenchus" of Socrates, indicate that contemporary with Socrates there were eristics whose aims were not his, (3) that, whereas the sophist of the final definition "disputes, and teaches others to dispute, about things divine, cosmical, metaphysical, legal, political, technical, in fact, about all things," we have no ground for supposing that the Megarians and the Cynics used their eristic for any purpose except the defence of their logical heresies.

Nor is it possible to accept the statements that "the splendid genius, the lasting influence, and the reiterated polemics of Plato have stamped the name sophist upon the men against whom he wrote as if it was their

recognized, legitimate, and peculiar designation," and that "Plato not only stole the name out of general circulation, in order to fasten it specially upon his opponents the paid teachers, but also connected with it express discreditable attributes which formed no part of its primitive and recognized meaning and were altogether distinct from, though grafted upon, the vague sentiment of dislike associated with it." That is to say, Grote supposes that for at least eight and forty years, from 447 to 399, the paid professors had no professional title, that, this period having elapsed, a youthful opponent succeeded in fastening an uncomplimentary title, not only upon the contemporary teachers, but also, retrospectively, upon their predecessors, and that, artfully enhancing the indignity of the title ascribed, he thus obscured, perverted, and effaced the records and the memories of the past. Manifestly all three propositions are antecedently improbable. But more than this whereas in the nomenclature of Plato's contemporaries Protagoras, Gorgias, Socrates, Dionysodorus, and Isocrates were all of them sophists, Plato himself in his careful investigation summarized above limits the meaning of the term so that it shall include the humanists and the eristics only. Now, if his use of the term was stricter than the customary use, he can hardly be held answerable for the latter.

Nor is Grote altogether just in his account of Plato's attitude towards the several sophists, or altogether judicious in his appreciation of Plato's testimony. However contemptuous in his portraiture of Hippias and Dionysodorus, however severe in his polemic against Isocrates, Plato regards Protagoras with admiration and Gorgias with respect. While he emphasizes in the later sophists the consequences of the fundamental error of sophistry,—its indifference to truth,—he does honour to the genius and the originality of the leaders of the movement. Indeed, the author of this article finds in the writings of Plato a grave and discriminating study of the several forms of sophistry, but no trace whatsoever of that blind hostility which should warrant us in neglecting his clear and precise evidence.

In a word, the present writer agrees with Grote that the sophists were not a sect or school with common doctrine or method, that their theoretical and practical morality was neither above nor below that of their age, being, in fact, determined by it, and that Plato and his followers are not to be regarded as the authorized teachers of the Greek nation, nor the sophists as the dissenters, but *vice versa*. At the same time, in opposition to Grote, he maintains that the appearance of the sophists marked a new departure, in so far as they were the first professors of "higher education" as such, that they agreed in the rejection of "philosophy," that the education which they severally gave was open to criticism, inasmuch as, with the exception of Socrates, they attached too much importance to the form, too little to the matter, of their discourses and arguments, that humanism, rhetoric, politics, and disputation were characteristic, not of all sophists collectively, but of sections of the profession, that Plato was not the first to give a special meaning to the term "sophist" and to affix it upon the professors of education, and, finally, that Plato's evidence is in all essentials trustworthy.

Bibliography.—On the significance of the sophistical movement, see E. Zeller, *Philosophie d. Griechen*, 4th ed., Leipzig, 1876, i. 832-1041 (*Presocratic Philosophy*, London, 1881, ii. 394-516), G. Grote, *History of Greece*, London, 1851, &c., ch. lxvii., E. M. Cope, "On the Sophists," and "On the Sophistical Rhetoric," in *Four Glass and Sac. Philol.*, Cambridge, ii. 1855, and iii. 1857, an erudite but inconclusive reply to Grote, H. Sidgwick, "The Sophists," in *Four of Philol.*, Cambridge, iv. 1872, and v. 1874, a brilliant defence of Grote, A. W. Benn, *The Greek Philosophers*, London, 1882, i. 50-107. Compare E. Zeller, vol. i. pp. 576-577.

For lists of treatises upon the life and teaching of particular sophists, see Ueberweg, *Grundriss d. Gesch. d. Philos.*, i §§ 27-32 (*History of Philosophy*, London, 1880). On the later use of the term "sophist," see RHETORIO (H J.A.)

SOPHOCLES, the most perfect, and next to Æschylus the greatest, of Greek tragic poets, was born 495 B.C. and died 406 B.C. As in the case of other Athenian celebrities, various particulars of his life are handed down, few of which, however, deserve much attention, even the reports attributed to contemporaries being mostly trivial if not puerile. He is known to have reached old age, and his career as a dramatist is believed to have extended over more than sixty years (468-406). His father's name was Sophillus, of the deme Colonus Hippius, the aristocratic quarter, where the Government of the Four Hundred was afterwards constituted. The family burial-place is said by the anonymous biographer to have been ten stadia from the city, on the Decelæan Way. These facts run counter to the tradition, which seems to have been already discredited by Alexandrian critics, that Sophillus was an artisan. The date assigned for the poet's birth is in accordance with the tale that young Sophocles, then a pupil of the musician Lamprus, was chosen to lead the chorus of boys (ἡθέων λεκτοί, *Æd. Tyr.*, 18) in the celebration of the victory of Salamis (480 B.C.). The time of his death is fixed by the allusions to it in the *Frogs* of Aristophanes and in the *Muses*, a lost play of Phrynichus, the comic poet, which were both produced in 405 B.C., shortly before the capture of the city. And the legend which implies that Lysander allowed him funeral honours is one of those which, like the story of Alexander and Pindar's house at Thebes, we can at least wish to be founded on fact, though we should probably substitute Agis for Lysander. Apart from tragic victories, the event of Sophocles's life most fully authenticated is his appointment at the age of fifty-five as one of the generals who served with Pericles in the Samian War (440-439 B.C.). Conjecture has been rife as to the possibility of his here improving acquaintance with Herodotus, whom he probably met some years earlier at Athens (see HERODOTUS). But the distich quoted by Plutarch—

Ἦιδὸν Ἡροδότῳ τεύξει Σοφοκλῆς ἐτέων ἄν
Πέντ' ἐπὶ πεντήκοιτα—

is a slight ground on which to reject the stronger tradition according to which Herodotus was ere this established at Thuri, and the coincidences in their writings may be accounted for by their having drawn from a common source. The fact of Sophocles's generalship is the less surprising if taken in connexion with the interesting remark of his biographer (whose *Life*, though absent from the earliest MS. through some mischance, bears marks of an Alexandrian origin) that he took his full share of civic duties, and even served on foreign embassies—*Καλῶς τ' ἐπαιδεύθη καὶ ἐτράφη ἐν κύριοις, καὶ ἐν πολιτείᾳ καὶ ἐν πρεσβείαις ἐξητάζετο*. The large acquaintanceship which this implies, not only in Athens, but in Ionic cities generally, is a point of main importance in considering the opportunities of information at his command. And, if we credit this assertion, we are the more at liberty to doubt the other statement, though it is not incredible, that his appointment as general was due to the political wisdom of the *Antigone*.

The testimony borne by Aristophanes to the amiability of the poet's temper (ὁ δ' εὐκόλος μὲν εἰ θάδ', εὐκόλος δ' ἐκεῖ) agrees with the record of his biographer that he was universally beloved. And the anecdote recalled by Cephælus in Plato's *Republic*, that Sophocles welcomed the release from the passions which is brought by age, accords with the spirit of his famous Ode to Love in the *Antigone*. The Sophocles who, according to Aristotle (*Rhet.*,

ii 18), said of the Government of the Four Hundred that it was the better of two bad alternatives (probably the same who was one of the *probuli*) may or may not have been the poet. Other gossiping stories are hardly worth repeating,—as that Pericles rebuked his love of pleasure and thought him a bad general, though a good poet, that he humorously boasted of his own "generalship" in affairs of love, or that he said of Æschylus that he was often right without knowing it, and that Euripides represented men as they are, not as they ought to be. Such trifles rather reflect contemporary or subsequent impressions of a superficial kind than tell us anything about the man or the dramatist. The gibe of Aristophanes (*Par.*, 695 sq.), that Sophocles in his old age was become a very Simonides in his love for gain, may turn on some perversion of fact,¹ without being altogether fair to either poet. It is certainly irreconcilable with the remark (*Vit. Anon.*) that in spite of pressing invitations he refused to leave Athens for kings' courts. And the story of his indictment by his son Iophon for incompetence to manage his affairs,—to which Cicero has given some weight by quoting it in the *De Senectute*,—appears to be really traceable to Satyrus (*flor. c.* 200 B.C.), the same author who gave publicity to the most ridiculous of the various absurd accounts of the poet's death,—that his breath failed him for want of a pause in reading some passage of the *Antigone*. Satyrus is at least the sole authority for the defence of the aged poet, who, after reciting passages from the *Æd. Col.*, is supposed to have said to his accusers, "If I am Sophocles I am no dotard, and if I dote I am not Sophocles." On the other hand, we need not the testimony of biographers to assure us that he was devoted to Athens and renowned for piety. He is said to have been priest of the hero Alcon (or Halon) in his old age, and himself to have received divine honours after death.

That the duty of managing the actors as well as of training the chorus belonged to the author is well known. But did Æschylus act in his own plays? This certainly is implied in the tradition that Sophocles, because of the weakness of his voice, was the first poet who desisted from doing so. In his *Thamyra*, however, he is said to have performed on the lyre to admiration, and in his *Nausicaa* (perhaps as coryphæus) to have played gracefully the game of ball. Various minor improvements in decoration and stage carpentry are attributed to him,—whether truly or not who can tell? It is more interesting, if true, that he wrote his plays having certain actors in his eye, that he formed an association (*θίασοι*) for the promotion of liberal culture, and that he was the first to introduce three actors on the stage.² It is asserted on the authority of Aristoxenus that Sophocles was also the first to employ Phrygian melodies. And it is easy to believe that *Al.*, 693 sq., *Trach.*, 205 sq., were sung to Phrygian music, though there are strains in Æschylus (*eg.*, *Choeph.*, 152 sq., 423 sq.), which it is hard to distinguish essentially from these. Ancient critics had also noted his familiarity with Homer, especially with the *Odyssey*, his power of selection and of extracting an exquisite grace from all he touched (whence he was named the "Attic Bee"), his mingled felicity and boldness, and, above all, his subtle delineation of human nature and feeling. They observed that the balanced proportions and fine articulation of his work are such that in a single half line or phrase he often conveys the impression of an entire character.

¹ If any of Sophocles's elegies or odes were "pot boilers," this might be due rather to his easy temper (*ευκόλια*) in yielding to a *pu vale* habit of the time than to any *meum s.* (*βασιλίστα* or *γλισχρότης*).

² If this was so, it must have been previous to the appearance of the Orestean trilogy.

Nor is this verdict of antiquity likely to be reversed by modern criticism. The object of the present article, however, is not to praise Sophocles, but rather to describe him. And it is time to turn from Alexandrian or Byzantine fancies and judgments to the poet's extant works.

His minor poems, elegies, pæans, &c., have all perished, and of his hundred and odd dramas only seven remain. These all belong to the period of his maturity (he had no decline), and not only the titles (as Lessing said) but some scanty fragments of more than ninety others have been preserved. Several of these were, of course, satyric dramas. And this recalls a point of some importance, which has been urged on the authority of Suidas, who says that "Sophocles began the practice of pitting play against play, instead of the tetralogy." If it were meant that Sophocles did not exhibit tetralogies, this statement would have simply to be rejected. For the word of Suidas (950 A D) has no weight against quotations from the lists of tragic victories (*διδασκαλίας*) which there is no other reason for discrediting. The remark might be due to the impression made on some critics by the greater complexity and completeness of a play of Sophocles—say the *Œdipus Tyrannus* or *Antigone*—as compared, say, with the *Perseus* or the *Septem contra Thebas*. It is distinctly asserted, for example, on the authority of the *διδασκαλίας*, that the *Bacchæ* of Euripides, certainly as late as any play of Sophocles, was one of a trilogy or tetralogy. And if the custom was thus maintained for so long it was clearly impossible for any single competitor to break through it. But it seems probable that the trilogy had ceased to be the continuous development of one legend or cycle of legends,—“presenting Thebes or Pelops’ line,”—if, indeed, it ever was so exclusively, and if, as Schöhl and others have suggested, a Sophoclean tetralogy was still linked together by some subtle bond of tragic thought or feeling, this would not affect the criticism of each play considered as an artistic whole. At the same time it appears that the satyric drama lost its grosser features and became more or less assimilated to the milder form of tragedy. And these changes, or something like them, may have given rise to the statement in Suidas.¹

If the diction of Sophocles sometimes reminds his readers of the *Odyssey*, the subjects of his plays were more frequently chosen from those later epics which subsequently came to be embodied in the epic cycle,—such as the *Æthiopis*, the *Little Iliad*, the *Ilupersis*, the *Cypria*, the *Nosti*, the *Telegonia* (all revolving round the tale of Troy), the *Thebæica*, the *Oixaliās alwais*, and others, including probably, though there is no mention of such a thing, some early version of the Argonautic story. In one or other of these heroic poems the legends of all the great cities of Hellas were by this time embodied, and, though there must also have been a cloud of oral tradition floating over many a sacred spot, the dramatic poet does not seem, unless in the *Œdipus Coloneus*, to have directly drawn from this. He was content to quarry from the epic rhapsodies the materials for his more concentrated art, much as Shakespeare made use of Hollingshed or Plutarch, or as the subjects of Tennyson's *Idylls of the King* have been taken from Sir Thomas Malory. As Sophocles has been accused of narrowing the range of tragic sympathy from Hellas to Athens, it deserves mention here that, of some hundred subjects of plays attributed to him, fifteen only are connected with Attica, while exactly the same

number belong to the tale of Argos, twelve are Argonautic, and thirty Trojan. Even Corinthian heroes (Bellerophon, Polydus) are not left out. It seems probable on the whole that, within the limits allowed by convention, Sophocles was guided simply by his instinctive perception of the tragic capabilities of a particular fable. This was evidently Lessing's view, and may be confirmed by quoting his striking remarks upon the subject of one of the lost tragedies, the *Thyestes at Siryon*—

“Nach der abentheuerlichen Wahlzeit, die ihm sein Bruder bereite, flog er nach Siryon. Und hier war es wo er, auf Befragung des Orakels, wie er sich an seinem Bruder rächen sollte, die Antwort bekam, er sollte seine eigne Tochter entehren. Er überfiel dies auch unbekannter Weise, und aus diesem Beischlafe ward Egesth, der den Atreus hernach umbrachte, erzeugt. Die Verzeihung einer gezeichneten Prinzessin! Von einem Unbekannten! In welchem sie endlich ihren Vater erkennt! Eine von ihrem Vater entehrte Tochter! Und aus Rache entehrt! Gezeichnet einen Mörder zu gehören! Welche Situationen! welche Scenen!”

To say that subsidiary or collateral motives were never present to Sophocles in the selection of a subject would, however, be beyond the mark. His first drama, the *Triptolemus*, must have been full of local colouring, the *Ajax* appealed powerfully to the national pride, and in the *Œdipus Coloneus* some faint echoes even of oligarchical partisanship may be possibly discerned. But, even where they existed, such motives were collateral and subsidiary, they were never primary. All else was subordinated to the dramatic, or, in other words, the purely human, interest of the fable. This central interest is even more dominant and pervading in Sophocles than the otherwise supreme influence of religious and ethical ideas. The idea of destiny, for example, was of course inseparable from Greek tragedy. Its prevalence was one of the conditions which presided over the art from its birth and, unlike Æschylus who wrestles with gods, our poet simply accepts it, both as a *datum* of tradition and a *fact* of life. But in the free handling of Sophocles even fate and providence are adumbrated to tragic art. They are instruments through which sympathetic emotion is awakened, deepened, intensified. And, while the vision of the eternal and unwritten laws was holier yet, for it was not the creation of any former age, but rose and culminated with the Sophoclean drama, still to the poet and his Periclean audience this was no abstract notion, but was inseparable from their impassioned contemplation of the life of man—so great and yet so helpless, aiming so high and falling down so far, a plaything of the gods and yet essentially divine. This lofty vision subdued with the serenity of awe the terror and pity of the scene, but from neither could it take a single tremor or a single tear. Emotion was the element in which Greek tragedy lived and moved, albeit an emotion that was curbed to a serene stillness through its very depth and intensity.

The final estimate of Sophoclean tragedy must largely depend upon the mode in which his treatment of destiny is conceived. That Æschylus had risen on the wings of faith to a height of prophetic vision, from whence he saw the triumph of equity and the defeat of wrong as an eternal process moving on toward one divine event,—that he realized sin, retribution, responsibility, as no other ancient did,—may be gladly conceded. But it has been argued² that because Sophocles is saddened by glancing down again at actual life,—because in the fatalism of the old fables he finds the reflexion of a truth,—he in so far takes a step backward as a tragic artist. Now is this altogether just? His value for what is highest in man is none the less because he strips it of earthly rewards, nor is his reverence for eternal law less deep because he knows that its workings are sometimes pitiless. Nor, once more,

¹ The advantages and defects of the trilogy as a dramatic form are admirably stated by G. Gunther, *Grundzüge der Tragischen Kunst*, Berlin, 1885. The small number of victories attributed to Sophocles, in proportion to the number of his plays, is only intelligible on the supposition that these were presented in groups.

² Gunther, *op. cit.*

does he disbelieve in providence, because experience has shown him that the end towards which the supreme powers lead forth mankind is still unseen. We miss something of the exultant energy of the Marathonian man, but under the grave and gentle guidance of his successor we lose nothing of the conviction that, "because right is right, to follow right were wisdom in the scorn of consequence." Not only the utter devotion of Antigone, but the lacerated innocence of Oedipus and Deianira, the tempted truth of Neoptolemus, the essential nobility of Ajax, leave an impress on the heart which is ineffaceable, and must elevate and purify while it remains. In one respect, however, it must be admitted that Sophocles is not before his age. There is an element of unrelieved vindictiveness, not merely inherent in the fables, but inseparable from the poet's handling of some themes, which is only too consistent with the temper of the "tyrant city." Aeschylus represents this with equal dramatic vividness, but he associates it, not with heroism, but with crime.

Sophocles is often praised for skilful construction. But the secret of his skill depends in large measure on the profound way in which the central situation in each of his fables has been conceived and felt. Concentration is the distinguishing note of tragedy, and it is by greater concentration that Sophocles is distinguished from other tragic poets. In the *Septem contra Thebas* or the *Prometheus* there is still somewhat of epic enlargement and breadth, in the *Ileuba* and other dramas of Euripides separate scenes have an idyllic beauty and tenderness which affect us more than the progress of the action as a whole, a defect which the poet sometimes tries to compensate by some novel denouement or catastrophe. But in following a Sophoclean tragedy we are carried steadily and swiftly onward, looking neither to the right nor to the left, the more elaborately any scene or single speech is wrought the more does it contribute to enhance the main emotion, and if there is a deliberate pause it is felt either as a welcome breathing space or as the calm of brooding expectancy.

The result of this method is the union, in the highest degree, of simplicity with complexity, of largeness of design with absolute finish, of grandeur with harmony. Superfluities are thrown off without an effort through the burning of the fire within. Crude elements are fused and made transparent. What look like ornaments are found to be inseparable from the organic whole. Each of the plays is admirable in structure, not because it is cleverly put together, but because it is so completely alive.

The spectator of a Sophoclean tragedy was invited to witness the supreme crisis of an individual destiny, and was possessed at the outset with the circumstances of the decisive moment. Except in the *Trachiniae*, where the retrospective soliloquy of Deianira is intended to emphasize her lonely position, this exposition is effected through a brief dialogue, in which the protagonist may or may not take part. In the *Oedipus Tyrannus* the king's entrance and his colloquy with the aged priest introduce the audience at once to the action and to the chief person. In the *Ajax* and *Philoctetes* the entrance or discovery of the hero is made more impressive by being delayed. Immediately after the prologos the chorus enter, numbering fifteen, either chanting in procession as in the *Antigone* and *Oed. Tyr.*, or dispersedly as in the *Oed. Col.* and *Philoctetes*, or, thirdly, as in the *Electra*, where, after entering silently during the monody of the heroine, and taking up their position in the orchestra, they address her one by one. With a remarkable exception, to be noted presently, the chorus having once entered remain to the end. They always stand in some carefully adjusted

relation to the principal figure. The elders of Thebes, whose age and coldness throw into relief the fervour and the desolation of Antigone, are the very men to realize the calamity of Oedipus, and, while horror-stricken, to lament his fall. The rude Salaminian mariners are loyal to Ajax, but cannot enter into his grief. The Trachinian maidens would gladly support Deianira, who has won their hearts, but they are too young and inexperienced for the task. The noble Argive women can sympathize with the sorrows of Electra, but no sympathy can soothe her distress.

The parodos of the chorus is followed by the first scene or episode, with which the action may be said to begin. For in the course of this the spectator's interest is strongly roused by some new circumstance involving an unforeseen complication,—the awakening of Ajax (*Aj*), the burial of Polyneices (*Ant*), the dream of Clytemnestra (*El*), the dark utterance of Tiresias (*Oed. Tyr.*), the arrival of Lichas with Iole (*Trach.*), the report of Ismene announcing Creon's coming (*Oed. Col.*), the sudden entreaty of Philoctetes crossed by the entrance of the pretended mariner (*Phil*). The action from this point onwards is like a steadily flowing stream into which a swift and turbulent tributary has suddenly fallen, and the interest advances with rapid and continuous climax until the culmination is reached and the catastrophe is certain. The manner in which this is done, through the interweaving of the *ῥῆσις* and *στυχονυθία* of the dialogue with the *στάσιμα* of the chorus, and the *κομμοί* and *κομματικά* (where there is interchange between the chorus and the persons), is very different in different dramas, one of the principal charms of Sophocles being his power of ingenious variation in the employment of his resources. Not less admirable is the strength with which he sustains the interest after the *περὶ πύματα*,¹ whether, as in the *Antigone*, by heaping sorrow upon sorrow, or, as in the first *Oedipus*, by passing from horror to tenderness and unlocking the fountain of tears. The extreme point of boldness in arrangement is reached in the *Ajax*, where the chorus and Tecmessa, having been warned of the impending danger, depart severally in quest of the vanished hero, and thus leave not only the stage but the orchestra vacant for the soliloquy that precedes his suicide.

No such general description as has been here attempted can give even a remote impression of the march of Sophoclean tragedy,—by what subtle yet firm and strongly marked gradations the plot is unfolded, how stroke after stroke contributes to the harmonious totality of feeling, what vivid interplay, on the stage, in the orchestra, and between both, builds up the majestic, ever moving spectacle. Examine, for example, the opening scene or *πρόλογος* of the *Oedipus Tyrannus*. Its function is merely to propound the situation, yet it is in itself a miniature drama. First there is the silent spectacle of the eager throng of suppliants at the palace gate,—young children, youths, and aged priests. To them the king appears, with royal condescension and true public zeal. The priest expresses their heartfelt loyalty, describes the distress of Thebes, and, extolling Oedipus's past services, implores him to exercise his consummate wisdom for the relief of his people. The king's reply unveils yet further his incessant watchfulness and anxious care for his subjects. And he discloses a new object to their expectancy and hope. Creon, a royal person, had been sent to Delphi, and should ere then have returned with the response of Apollo. At this all hearts are trembling in suspense, when a figure is seen approaching. He is wreathed with Apollo's laurel, he looks cheerfully. What has Phoebus said? Another moment of suspense is interposed. Then the oracle is repeated,—so thrilling to

¹ A tragic action has five stages, whence the five acts of the modern drama—the start, the rise, the height, the change, the close.

the spectator who understands the story, so full of doubt and hope and dread to all the persons of the drama. "It is for the blood of Laius—his murderers are harboured in the land of Thebes. The country must be purged." That is the culminating point of the little tragedy. While Œdipus asks for information, while in gaiety of heart he undertakes the search, while he bids the folk of Cadmus to be summoned thither, the spectators have just time to take in the full significance of what has passed, which every word that is uttered sends further home. All this in 150 lines!

Or, once more, consider the employment of narrative by this great poet. The *Tyrannus* might be again adduced, but let us turn instead to the *Antigone* and the *Trachinæ*. The speech of the messenger in the *Antigone*, the speeches of Hyllus and the Nurse in the *Trachinæ*, occur at the supreme crises of the two dramas. Yet there is no sense of any retardation in the action by the report of what has been happening elsewhere. Much rather the audience are carried breathlessly along, while each speaker brings before their mental vision the scene of which he had himself been part. It is a drama within the drama, an action rising from its starting point in rapid climax, swift, full, concentrated, until that wave subsides, and is followed by a moment of thrilling expectation. Nor is this all. The narrative of the messenger is overheard by Eurydice, that of Hyllus is heard by Deianira, that of Nurse by the chorus of Maidens. And in each case a poignancy of tragic significance is added by this circumstance, while the *poiesis* in the *Antigone*, and that of Hyllus in a yet higher degree, bind together in one the twofold interest of an action which might otherwise seem in danger of distracting the spectator.

So profound is the contrivance, or, to speak more accurately, such is the strength of central feeling and conception, which secures the grace of unity in complexity to the Sophoclean drama.

The proportion of the lyrics to the level dialogue is considerably less on the average in Sophocles than in Æschylus, as might be expected from the development of the purely dramatic element, and the consequent subordination of the chorus to the protagonist. In the seven extant plays the lyrical portion ranges from one-fifth to nearly one-third, being highest in the *Antigone* and lowest in the *Œdipus Tyrannus*. The distribution of the lyrical parts is still more widely diversified. In the *Electra*, for instance, the chorus has less to do than in the *Œdipus Tyrannus*, although in the former the lyrics constitute one-fourth, and in the latter only one-fifth of the whole. But then the part of *Electra* is favourable to lyrical outbursts, whereas it is only after the tragic change that Œdipus can appropriately pass from the stately *senarius* to the broken language of the dochmiac and the "lamenting" anapaest. The protagonists of the *Ajax* and the *Philoctetes* had also large opportunities for vocal display.

The union of strict symmetry with freedom and variety which is throughout characteristic of the work of Sophocles is especially noticeable in his handling of the tragic metres. In the iambs of his dialogue, as compared with those of Æschylus, there is an advance which may be compared with the transition from "Marlowe's mighty line" to the subtler harmonies of Shakespeare. Felicitous pauses, the linking on of line to line, trisyllabic feet introduced for special effects, alliteration both hard and soft, length of speeches artfully suited to character and situations, adaptation of the *cæsura* to the feeling expressed, are some of the points which occur most readily in thinking of his *senarii*. A minute speciality may be noted as illustrative of his manner in this respect. Where a line is broken by a pause towards the end, and the latter

phrase runs on into the following line, elision sometimes takes place between the lines, e.g. (*Œd. Tyr.*, 332-3) —

Εγω οὐτ' ἐμάντων οὐτε σ' ἀλγυνᾷ τι ταῦτ'
ἔλλας ἀλέγχεις,

This is called *synapheia*, and is peculiar to Sophocles.

He differentiates more than Æschylus does between the metres to be employed in the *κορμοί* (including the *λορμα-ια*) and in the choral odes. The dochmius, cretic, and free anapaest are employed chiefly in the *κορμοί*. In the stasima he has greatly developed the use of logaedic and particularly of glyconic rhythms, and far less frequently than his predecessor indulges in long continuous runs of dactyls or trochees. The light trochaic line $\underline{\text{—}} \text{—} \underline{\text{—}} \text{—}$, so frequent in Æschylus, is comparatively rare in Sophocles. If, from the very severity with which the choral element is subordinated to the purely dramatic, his lyrics have neither the magnificent sweep of Æschylus nor the "linked sweetness" of Euripides, they have a concinnity and point, a directness of aim, and a truth of dramatic keeping, more perfect than is to be found in either. And even in grandeur it would be hard to find many passages to bear comparison with the second stasimon, or central ode, either of the *Antigone* (*εἰδαίμοις οἶοι κακῶν*) or the first *Œdipus* (*εἰ μοι ξυεῖν φέροι-τι*). Nor does anything in Euripides equal in grace and sweetness the famous eulogy on Colonus (the poet's birthplace) in the *Œdipus Coloneus*.

Sophocles was edited (probably from the Venetian MSS.) by Aldus Manutius, with the help of Musurus, in 1502. The Junine editions, in which the text of Aldus was slightly modified with the help of Florentine MSS., were published in 1522, 1547, respectively. An edition of the Scholia, very nearly corresponding to those on the margin of the Medicean or chief Laurentian MS (La or L) had previously appeared at Rome in 1518. The first great modification of the text was due to Turnebus, who had access to the Parisian MSS., but he was not fortunate in his selection. The earliest editors had been aware that the traditional arrangement of the metres was faulty, but little way had been made towards a readjustment. Now it so happens that the Parisian MS T, which is a copy of the recension of Triclinius, an early 14th-century scholar, contains also the metrical views of the same editor, and, having found (as he erroneously supposed) a sound authority, Turnebus blindly adopted it, and was followed in this by H. Stephanus (1568), Capparoner, and Vauvillers in France, and Canter in Holland (who was the first to mark the correspondence of *strophe* and *antistrophe*). This error was to a large extent corrected by Brunel (1786), who rightly preferred Par A (2712), a 13th-century MS, belonging as it happened, to the same family with Ven. 467, which Aldus had mainly followed. Thus after nearly three centuries the text returned (though with many conjectural variations some of which were due to Saenger, Auratus, and other earlier scholars) into nearly the same channel as at first. Meanwhile the study of Greek metres had greatly advanced, and, while much licence was given to conjecture (in which Valckenaeer and Porson were especially happy), documentary evidence was also better weighed and sifted. The collation of the Laurentian MS. by Peter Elmsley in 1825 (with his transcription of the Scholia) may be said to mark the most important epoch in the textual criticism of Sophocles. But the great work of Gottfried Hermann, whose editions (1823-1830), which are critical in every sense of the word, are adorned with an ample Latin commentary, made perhaps the longest step in advance. Since Hermann the editors of Sophocles have been very numerous. The list, from Schneider to Wecklein and Pappageorgius amongst Continental scholars and from Linwood to Jebb (who is last, not least) amongst our own, is too long for insertion here.

(L.C.)

SOPHRON of Syracuse, next to Epicharmus the greatest representative of Sicilian comedy, flourished about 430 B.C. He was the author of mimes, written in prose, containing both male and female characters—*Μῦμοι ἀνδρῶν* and *Μῦμοι γυναικῶν*—and depicting scenes from the daily life of the Sicilian Greeks. From the extremely scanty fragments which remain of his writings we can only see that he used the local dialect, frequently sacrificing refinement to vigour, he sometimes reminds us of Plautus in his employment of bold and expressive figures and turns of expression. But we can judge of the dramatic power

and vivacity of his compositions from the story that Plato first introduced them to Athens, and studied them in order to give animation to his own dialogues, and some idea of the general character of his imitations may be derived from the 2d and 15th idyls of Theocritus, which are said to have been imitated from the *Ἀλέστρια* and *Ἰσθμιαῖοι* of his Syracusan predecessor.

The fragments of Sophron, most of which have been preserved to illustrate some point of grammar or dialect, are collected in Athens, *De Græci Litteræ Dialectis*, vol. II pp. 461-470.

SOPRON See OIMNABUR.

SORA, a city of Italy, at the head of a circondario in the province of Caserta (Terra di Lavoro), is built in a plain on the banks of the Garigliano and on the highway from Rome to Tivoli and Avezzano to Naples. It is the seat of important manufactures,—wool spinning, cloth weaving, and paper making,—this last industry dating from the time of Murat. The original cathedral, consecrated by Pope Adrian IV in 1155, was destroyed by the earthquake of 1631. The population of the city was 8768 in 1861 and 5111 (commune 13,208) in 1881.

Sora, an ancient Volscian town, was three times captured by the Romans, in 345, 311, and 305 B.C., before they married, in 303, by means of a colony 4000 strong, to confirm its annexation. In 209 it was one of the colonies which refused further contributions. By the lex Julia it became a municipium, but under Augustus it was colonized by soldiers of the 4th legion. The castle of Sorella, built on the rocky hill above the town, was in the Middle Ages a stronghold of some note, on one occasion it held out successfully against a whole year's vigorous siege by William II. of Sicily. Alfonso of Aragon made Sora a duchy for the Cantelmo, it was afterwards seized by Pius II., but, being restored to the Cantelmo by Sixtus IV., it ultimately passed to the Della Rovere of Urbino. Against Cesar Borgia the city was heroically defended by Giovanni di Montefeltro. Captured by the marquis of Pescara for Charles V., it was by him bestowed on Carlo Caracciolo, duke of Crocy and Arceot, but Caracciolo being afterwards bought out, the duchy was restored to the duke of Salaparuta. By Gregory XIII. it was purchased for 11,000 ducats and bestowed on his son Buoncompagni, the ancestor of the line of Buoncompagni Ludovisi. In ancient times Sora was the birthplace of the Deici, Attillus Regulus, and Lucius Mummius, and of its modern celebrities Cardinal Baronius is one. The now ruined abbey church of San Domenico, founded in 1104 on the left bank of the Liri above the town, is believed to occupy the site of Cicero's family villa and birthplace. It consisted of a nave and two aisles, all ending in circular apses.

SORAU, an industrial town and railway junction in the south of Brandenburg, Prussia, is situated 51 miles to the south east of Frankfurt-on the Oder, and not far from the Silesian border. Said to be one of the oldest towns in Lower Lusatia, Sorau contains a number of ancient buildings, among which the most prominent are several of the churches (one dating from 1201), the town house, built in 1260, and the old palace of 1207. The new palace was erected in 1711. The varied manufactures of the town comprise cloth, linen, wax, candles, starch, bone meal, &c. The population, 3764 in 1816, was 13,668 in 1885, upwards of 12,000 of them being Lutherans.

Sorau is said to have existed in 840 and to have belonged to the abbey of Fulda till the 12th century. It received town rights in 1260. With the surrounding district, known as the barony of Sorau, it became the seat of successive noble families, and in 1400 it was united with the barony of Triebel. The last count of Prohnitz, whose ancestor had purchased both baronies from Frederick of Bohemia in 1556, sold them to the elector of Saxony for an annuity of 12,000 thalers (41800). In 1816 Saxony had to cede them to Prussia, after holding them for fifty years.

SORBONNE, the name formerly borne by the old faculty of theology in Paris, and now applied to the seat of the *académie* of that city and of the three faculties of theology, science, and literature. (See *LITTÉRATURE*, vol. IX, p. 513, *PARIS*, vol. VIII, p. 281, and *UNIVERSITIES*.) The Sorbonne owes its origin and its name to Robert de Sorbon, a poor priest of Champagne, who, arriving in Paris about the beginning of the reign of St Louis, attained high repute by his sanctity and eloquence, and was

appointed by the king to be his chaplain. Assisted by royal liberality, he built upon Mont Sainte Geneviève a modest establishment in which were accommodated seven priests charged with the duty of teaching theology gratuitously, to this he added a college of preparatory studies, all under the direction of a provisor, under whom was an annual prior who had the actual management. The new institution was authorized by letters patent of 1255, and canonically sanctioned by Pope Alexander IV in 1259. Destined originally for poor students, the Sorbonne soon became a meeting place for all the students of the university of Paris, who resorted thither to hear the lectures of the most learned theologians of the period,—Guillaume de Saint-Amour, Landes de Domai, Laurent l'Anglais, Pierre d'Ailly. At the close of the century it was organized into a full faculty of theology, and under this definitive form it conferred bachelor's, licentiate's, and doctor's degrees, and the severity of its examinations gave an exceptional value to its diploma. The so called "thèse Sorbonique," instituted towards the beginning of the 14th century, became the type of its order by the length and difficulty of its tests. Ultimately the professors of the Sorbonne came to be resorted to, not only for lectures and examinations, but also for dogmatic decisions and judgments in canon law, the clergy of France and of the whole Catholic world had recourse to them in difficult cases, and the Curia Romana itself more than once laid its doubts before them, giving them the title of "Concilium in Galia subsistens." The Sorbonne took a leading part in the religious discussions which agitated France during the 16th and 18th centuries, and its influence thus inevitably extended to political questions. During the insanity of Charles VI it helped to bring about the absolution of Jean Sans Peur for the assassination of the duke of Orleans. Shortly afterwards it demanded and supported the condemnation of Joan of Arc, during the Reformation it was the animating spirit of all the persecutions directed against Protestants and unbelievers without having advised the massacre of St Bartholomew, it did not hesitate to justify it, and it inflamed the League by its vigorous anathemas against Henry III and the king of Navarre, hesitating to recognize the latter even after his abjuration. From this point dates the beginning of its decadence, and, when Richelieu in 1629 ordered the reconstruction of its church and buildings, the following prophetic couplet was circulated—

*Instaurata ruet jamjam Sorbona Caduca
Dum fuit, inconvulsa stetit, renovata peribit*

The declaration of the clergy in 1682, which it subscribed, proved fatal to its authority with the Curia Romana, it revived for a short time under Louis XV during the struggle against Jansenism, but this was its last exploit, it was suppressed like the old universities in 1790. To the Sorbonne belongs the glory of having introduced printing into France in 1469 within its precincts it assigned quarters for Ulric Gering and two companions in which to set up their presses.

When the university of France was organized in 1808 the Sorbonne became the seat of the *académie* of Paris, and between 1816 and 1821 the faculties of theology, science, and literature were installed there with their libraries. All the great university functions are held within its great amphitheatre. Since 1861 there has annually been held in the Sorbonne at Easter an official congress in which are represented the learned societies of the départements, there are five sections—those of archeology, history, the moral and political sciences, the physical sciences, geography,—which hold separate sittings. The fine arts form a sixth section, with a special organization.

A reconstruction of the buildings of the Sorbonne, pro-

jected by Napoleon III, was begun in 1884, under the architectural direction of Nenot. The old church, containing the tomb of Richelieu is to be retained on account of its artistic merit.

SORGHUM See **MILLET**

SORIA, a province of Spain, in Old Castile, bounded on the N. by Logroño, E. by Saragossa, S. by Guadalajara, and W. by Segovia and Burgos, the area is 3836 square miles. It is a bleak and lofty region, being bounded on three sides by mountains. A range of low sierras on the north, and the great Sierra de Moncayo on the east, separate the valley of the Duero (Douro) from that of the Ebro, while on the south it is divided from that of the Tagus by a continuation of the Sierra Guadarrama. The whole of the province belongs to the region watered by the Duero and its affluents. This river rises in the northern mountains, and traverses the province in a circuitous course, first to the south and then to the west. The other rivers are mostly affluents of the Duero, such as the Tuerto, San Pedro, &c., but a few of the tributaries of the Ebro have their sources within the limits of the province. The soil is not remarkable for fertility, on the contrary, a large proportion of the area is occupied with barren mountains, which are covered with snow for a great part of the year. There are, however, in some places extensive forests of pine, oak, and beech, while in others there are large tracts of pasture land, on which numbers of cattle, sheep, and swine are reared. Grain and vegetables are raised, but neither of very good quality nor in sufficient quantities to supply the wants of the population. The climate is cold and dry, and the scenery grand, but not very pleasing in its character. Most of the people are employed in farming and rearing cattle, but the cutting and sawing of timber and the preparation of charcoal also occupy a considerable number. There is a great want of roads in this part of the country, and commerce is consequently very limited. Fine wool was formerly an important production of the province, but of late years it has considerably fallen off. The only important article of trade at present is timber, which is sent to Madrid and Aragon. Soria is divided into five partidos judiciales and 345 ayuntamientos. The population was returned in 1877 as 153,654. There is a bishop (suffragan of Burgos), resident at Osma. The only town of more than 5000 inhabitants is Soria.

SORIA, the capital of the above province, on a hill on the right bank of the Duero, 113 miles north east of Madrid, is an ancient town, still surrounded by walls which were built in the 13th century. It contains several squares, in one of which stand the court-house and prisons and in another the spacious palace of the dukes of Gomara. The churches of Santo Domingo and San Nicolas, the cloisters of the convent of San Juan, and several other ecclesiastical buildings are fine specimens of Romanesque work of the 12th and 13th centuries. The population is chiefly agricultural, but there are also flour-mills, tanneries, potteries, &c., and some trade in timber, wool, and fruit is carried on. Three and a half miles distant is the site of the ancient Numantia. But few traces of the old city, however, remain. A railway has long been projected between Soria and Calatayud, upon the Madrid and Saragossa line. The population in 1877 was 6286.

SORREL See **HORTICULTURE**, vol. xii. p. 288

SORRENTO, a city of Italy, in the province of Naples, on the north side of the peninsula that separates the Bay of Naples from the Bay of Salerno, about $1\frac{1}{2}$ miles to the east of Capo di Sorrento, crowned by the ruins of a temple of Neptune. Sorrento contains only a few unimportant remains of the magnificent buildings which made it in the time of Augustus a finer city than Naples, and its present

prosperity depends mainly on the reputation it enjoys as a summer watering-place, with a delightful and healthy climate, and situated amid picturesque coast scenery. The chief local industry is the inlaying of wood. In ancient times the Surrentine wines had a great repute. The population was 4254 in 1861 and 6089 in 1881.

Surrentum was of very ancient origin, but it does not appear frequently in history. A famous temple of Minerva stood on the Promontorium Surrentinum (now Punta della Campanella). In 1558 the corsair Piali attacked the town and carried off 2000 prisoners. Statins celebrated the delights of the Surrentine villa owned by his friend Pollius Felix, it was at Sorrento that Bernardo Tasso wrote his *Amadigi*, and Torquato Tasso was born in the town in 1544.

SOSIGENES, the astronomer who was employed by Julius Cæsar to reform the Roman calendar, 46 B.C. (see **CALENDAR**). Of his life nothing further is known, with the exception of two references to him by Pliny, which show that he left some astronomical treatises. The chief one is as follows —

"Tres autem snere sectæ Chaldaea, Ægyptia, Græca. His addidit quartam apud nos Cæsar dictator annos ad solis cursum redigens singulos, Sosigene perito scientiæ ejus adhibito, et ea ipsa ratio postea comperto errore correctæ est, ita ut XII annis continuis non interlaretur, quia cæperat sidera annus morari qui prius antecederat. Et Sosigenes ipse trinis commentationibus, quamquam diligentior ceteris, non cessavit tamen addubitare ipse semet corrigendo." — *H. N.*, xviii. 25.

From another passage (*H. N.*, ii. 8) we infer that Sosigenes maintained that Mercury moved in an epicycle about the sun, this doctrine is referred to by his contemporary Cicero, and it was also that of the Egyptians (see **PTOLEMY**). Sosigenes is commonly called an Egyptian and a Peripatetic, but this has arisen from his having been confounded with a Peripatetic philosopher of the same name who lived in the 2d century of the Christian era, and who will be briefly noticed below. It is most probable, however, that he was a Greek of Alexandria, for the following reasons: (1) Cæsar had just returned victorious from his Alexandrian expedition, which occupied parts of the years 48 and 47 B.C., when, with the assistance of Sosigenes, he settled the chronological question. (2) We learn from Plutarch (*Cæs.*, 59) that "Cæsar laid the problem (viz, the correction of the calendar) before the ablest philosophers and mathematicians," and at that time the school of Alexandria was world-famous. (3) We know that Cæsar was himself a diligent student of astronomy. Lucan, in a passage which refers to his correction of the calendar, represents him as saying that even in the midst of his campaigns he had always found time for astronomical pursuits —

"media inter prælia semper
Stellarum cælique plagis supersæpe vacavi,
Nec meas Endoxi vincitur Fastibus annus." — *l.* 185-7

(4) Macrobius says that Cæsar wrote a work on the motion of the stars, and expressly states, moreover, that he derived from the Egyptian schools his information on this subject, and also what he required for the correction of the calendar.¹ (5) Cæsar's arrangement was substantially the same as the reform of the Egyptian calendar in the year 238 B.C. under Ptolemy III. Evergetes, a fact which remained unknown until the discovery of the Decree of Canopus by Lepsius at Sanor Tanis in Egypt in the year 1866.

Zeller (*Phil. d. Gr.*, vol. iii. part 1, 2d ed., p. 705-6, note of p. 703, and p. 694, note 3), and after him, but in a more complete manner, Th. H. Martin (*Annales de la Faculté des Lettres de Bordeaux*, 2^e fasc., 1879), have shown, in opposition to the prevailing opinion, which had been formerly held by Zeller himself, that

¹ "Nec mirum si hæc digeries morsum repellençionis evasis, cui accessita est ab Ægypto postremæ correctionis auctoritas. Nam Julius Cæsar, ut siderum motus, de quibus non indoctos libros reliquit, ab Ægyptiis disciplinis hausit, ita hoc quoque ex eadem institutione mutuatus est, ut ad solis cursum finiendi anni tempus extenderet." — *Sat.*, i. 16.

the subject of this article has nothing in common but the name with Sosigenes the Peripatetic philosopher, author of a work on reituent spheres (*Σωσιγένης περί τῶν ἀνελιπτουσῶν σφαيرῶν*), which is referred to by Proclus (*Hypotyp.*, p. 111, ed. Halma) and followed by Simplicius in his *Commentary* on the treatise of Aristotle, *De Caelo*, author also of some other works, and master of Alexander of Aphrodisias, who lived at the end of the 2d and beginning of the 3d century after Christ, and who was the most celebrated of the commentators on Aristotle

SOTO See DE SOTO

SOUBISE, BENJAMIN DE ROHAN, DUC DE (c. 1589–1641), was the second son of René II, Vicomte de Rohan, and Catherine de Parthenay, and the younger brother of the soldier-writer Henri de ROHAN (q.v.). The seigneurie of Soubise came to the Rohans through Catherine, and Benjamin took the title as her second son. The exact date of his birth does not seem to be known, but it is believed to be 1589. He served his apprenticeship as a soldier under Prince Maurice of Orange in the Low Countries. But he hardly becomes an historical character before 1621, when the religious wars once more broke out in France. He and his brother Rohan were the soul of the Huguenot party,—the elder brother chiefly taking command on land and in the south, Soubise in the west and along the sea coast. His exploits in the conflict have been sympathetically related by his brother, who, if he was not quite an impartial witness, was one of the best military critics of the time. Soubise's chief performance was a singularly bold and well-conducted attack (in 1625) on the royalist fleet in the river Blavet (which included the cutting of a boom in the face of superior numbers after a style suggestive of the best days of the English navy) and the occupation of Oleron. Soubise commanded at Rochelle during the famous siege, and if we may believe his brother the failure of the defence and of the English attack on Rhé was mainly due to the alternate obstinacy of the townsfolk and the English commanders in refusing to listen to Soubise's advice. When surrender became inevitable he fled to England, which he had previously visited in quest of succour. He died in 1641, and his title afterwards served as the chief second designation (not for heirs apparent, but for the chief collateral branch for the time being) of the house of Rohan-Chabot, into which the older Rohan honours were carried by his niece Marguerite four years after his death.

SOUBISE, CHARLES DE ROHAN, PRINCE DE (1715–1787), peer and marshal of France, grandson of the Princesse de Soubise, who is known to history as one of the mistresses of Louis XIV., was born in Paris on July 15, 1715. He accompanied Louis XV. in the campaign of 1744–48, and attained high military rank, which he owed more to his courtiership than to his generalship. Soon after the beginning of the Seven Years' War, through the influence of Madame de Pompadour, he was put in command of a corps of 24,000 men, and on 4th November 1757 he sustained the crushing defeat of Rossbach (see vol. ix. pp. 588–591, where also some subsequent and more favourable episodes of his military career are briefly indicated). After 1763 he lived the life of an ordinary courtier in Paris, dying on July 4, 1787.

SOUDAN, or SŪDÂN (Bilād es-Sūdān, "Country of the Blacks"), a term applied by medieval Arab geographers to the region of Africa south of the Sahara mainly inhabited by peoples of Negro blood, hence corresponding to the expressions Nigritia, Negroland, at one time current amongst European writers. It lies mainly between 5° and 18° N. lat., consequently entirely within the tropics, and in its widest sense stretches right across the continent from Cape Verd on the Atlantic to Massowah on the Red Sea. But the term is more usually restricted to the region bounded N. by the Sahara, S. by Upper Guinea and the

lands draining to the Congo basin, W. and E. by Senegambia and the Abyssinian highlands respectively (see vol. i. plate II). Within these limits it has an extreme length of about 3000 miles between the Senegal river and Abyssinia, extending southwards at some points 660 miles, with a total area of perhaps 2,000,000 square miles, and a population approximately estimated at from 80 to 90 millions. From the arid and sandy northern wastes to the well-watered and arable Soudanese lands the transition is effected by an intermediate zone of level grassy steppes, partly overgrown with mimosa and acacias, with a mean breadth of about 60 miles, between 17° and 18° N. lat., but towards the centre reaching as far south as 15° N. Excluding this somewhat uniform transitional zone, the Soudan, properly so called, may be described as a moderately elevated region, diversified with extensive open or rolling plains, level plateaus, and even true highlands, especially in the south-west. It constitutes three distinct hydrographic systems, corresponding to the three main physical divisions of Western Soudan, draining through the Niger southwards to the Atlantic, Central Soudan, draining to the great central depression and landlocked basin of Lake Tchad, and Eastern (Egyptian) Soudan, draining through the Nile northwards to the Mediterranean. Between these systems the chief water-partings are—(1) the Marrah Mountains of Dar-Fur, whence flow the Bahr es-Salāmāt west to the Shari, and numerous intermittent wadies east to the Nile, (2) the Monbuttu uplands (Mount Baginze), separating the western head-streams of the White Nile from the Welle (Bahr Keta), which, according to the latest information, flows, not to the Shari as Schweinfurth supposed, but to the Congo through the Mbangi, (3) the so-called "Kong" Mountains, dividing the Niger basin from the Volta and other streams flowing in independent channels south to the Gulf of Guinea. The Adamawa highlands, culminating in Mount Alantika (9000 to 10,000 feet), do not form a divide, as was supposed, between the Binue (the main eastern tributary of the Niger) and the Logon and other streams flowing east to the Shari (the great southern affluent of Lake Tchad). Flegel, who has recently explored the upper course of the Binue, found that it sweeps right round the east foot of Mount Alantika, and is even navigable round this bend and some way southwards. On the other hand, the central hydrographic system of Lake Tchad has been greatly reduced in size since Lupton, Grenfell, and other recent explorers have made it evident that the Bahr Keta (Welle) flows not to the Shari but to the Congo basin. The Shari basin, which is now known not to reach farther south than about 6° N. lat., may even be almost considered, physically as well as politically, as subsidiary to the Niger hydrographic system, for there are indications that the Logon once flowed into the Binue by the Mayo-Kebbi. The Mayo-Kebbi is a long flat trough or valley in 9° 30' N. lat., with a level swamp at the bottom receiving as a backwater the overflow of the Logon, and also draining through the Binue to the Niger. By canalizing the Mayo-Kebbi the Binue and Shari basins might be permanently connected, in which case the Niger system would afford a navigable waterway from the Gulf of Guinea to the southernmost limits of Baghirmi.

From the Kong highlands, some of whose peaks appear to attain elevations of 6000 to 7000 feet, Western Soudan falls gradually towards the north and north-east down to the Great Desert, where the city of Timbuktu still maintains an altitude of 770 feet above sea level (Ibnr). South-east of the Niger the land rises in terraces of 1000 and even 3000 feet, above which isolated crests range from 5000 to 9000 feet. This little known western highland region, comprised between the Binue and the lower Niger

and extending from Adamawa to the Cameroons on the Bight of Biafra, corresponds with the eastern highland region of Abyssinia, lying between the Blue Nile and the Tagazze and dominating the Red Sea. North of Adamawa the land falls rapidly down to the vast depression of Central Sudan, whose lowest part is flooded with the waters of Lake Tchad (Chad or Tsad), the largest area of inland drainage, next to the Aral-Caspian basin, in the eastern hemisphere. This freshwater lacustrine depression, usually 10,000 square miles in extent, expands to 40,000 and even 50,000 square miles when swollen by the flood waters of its great feeders,—the Logon Shari from the south and the Koma lugu from the west. From the Tchad depression, which is still 1150 feet above the sea, the ground rises again eastwards in the direction of Wadai and Dar Fur, to heights of 3000 feet and upwards, culminating in the volcanic Jebel Marrah (6000 feet), which forms the natural eastern limit of Central Sudan, and the great divide between the Tchad and Nile basins. But politically the line between Central and Eastern Sudan is usually drawn more to the west along the conventional frontiers of Wadai and Dar-Fur, the latter province, although never completely reduced, being claimed as part of Egyptian Sudan. This region constitutes two distinct physical divisions,—the first comprising the provinces of Dar Fur and Kordofan, bounded E by the White Nile and S by the Bahr el-Arab, a tableland in which the steppe formation predominates, while the second is skirted east by the Bahr el Jebel and stretches from the Bahr el Arab southwards to the Monbuttu uplands, a vast plain watered by the numerous south-western headstreams of the White Nile. This plain rises gradually towards the south and south-west to the highlands, which appear to culminate in Mount Baginze, and which form the water-parting between the Nile and Congo basins. Included in Eastern Sudan is also the extensive plain of Sennar, stretching from the Nile eastwards to the Abyssinian uplands, and rising southwards to the Fazokl and Berta highlands.

The prevailing geological formations are the crystalline rocks, such as granites, diorites, slates, gneiss, underlying the old and new alluvia of the plains, and found associated with sandstones in the highlands. In the Kong Mountains the granites underlie the sandstones, but in the Lagale group (South Kordofan) they pass over to porphyries and syenites, interspersed with extensive diorites and auriferous quartz veins. Volcanic rocks (basalts, lavas, tufas) appear to be restricted to the isolated Defasaung and Alakika Mountains (Adamawa), although solfataras occur in the Tagalo district, where sulphur abounds. Mineral waters are also found in Dar Fur and Adamawa. The most widely diffused minerals are iron and copper, the oxides of iron occurring almost everywhere from the White Nile to the Niger, while pure copper is met especially in Dar Fur and Ferit. Gold is chiefly restricted to the Tagale and Kong Mountains, Bambarra, and Adamawa, and lead, natron, and tin are confined to a few isolated districts. Characteristic is the apparently total absence of limestones, coal, salt, and natron, the supplies of salt being imported mainly from the Sahara. Report, however, speaks of a large lake in the Jebel Marrah, from which salt is obtained.

The climate of Sudan is distinctly tropical, with two well-defined seasons, hot and rainy from April or May to October, warm and dry for the rest of the year. The former is accompanied by tremendous thunderstorms and continuous downpours flushing all the khors, wadies, and other watercourses, flooding large tracts along the lower courses of the Shari, Logon, Komadugu, and Niger, and interrupting the communications for weeks together in Baghirmi and Bornu. Before the rains set in the glass seldom falls below 98° or 100° F., rising at noon to 104°, while the mean annual temperature at Kaka (Bornu) is about 82° F. But in the dry season it is often lowered to 58° or 60°, and under the influence of the cool north-east winds water often freezes on the uplands, snow falls in Dar Fur, and fires are kept up in the houses in the central districts of Kano. The chief ailments are ague and other marsh fevers in the low lying tracts subject to inundations, the Guinea worm, cutaneous diseases, and leprosy. The fevers are dangerous alike to Europeans and natives.

An exuberant forest vegetation is favoured by the rich alluvial soil and tropical heat wherever moisture abounds. Of large growths the

most characteristic and widespread are—the baobab (*Adansonia*), reaching north to the 13th parallel and attaining a girth of 80 feet, the superb date palm, covering extensive tracts especially in the east, where it grows to a height of over 120 feet, the shea or butter tree (*Dansia butyrosa*), in the Niger basin and Kong uplands, the cotton tree, dum palm, tamarind, several varieties of euphorbias, acacias, and mimosas, the hehly (*Balanites aegyptiaca*), and jerjak of Wadai, which yields a kind of vegetable honey. Owing to the absence of salt the date-palm is very rare. The chief cultivated plants are cotton, maize, several kinds of durrah (*Sorghum vulgare*, *S. ceruum*, &c.), hemp, tobacco, gourds, water melons, indigo (of excellent quality and growing everywhere, wild and cultivated), and lastly the guru or kola nut (*Stereulia acuminata* and *S. macrocarpa*), which in Sudan takes the place of the coffee berry. Cotton of the finest quality has been raised on the rich alluvial plain of Lake and Sennar.

The beasts of prey, nowhere very numerous, are chiefly represented by the lion, panther, hyana, and jackal. Elephants in herds of 400 or 500 frequent the swampy districts about Lake Tchad, but are not found farther north than the 12th or 13th parallel. The ordinary African rhinoceros is common, and the rare one-horned species appears to have been met with in Wadai. The wild ass, zebra, giraffe, and antelopes in considerable variety abound on the eastern steppe lands, and endless species of monkeys in the forest districts. Crocodiles, some of great size, from 16 to 18 feet long, infest all the large rivers, the sangha, —a web-footed variety, occurring in the Niger. The hippopotamus also abounds in these waters, which teem with fish, mostly of unknown species. These attract numerous flocks of waterfowl,—palmers, spoonbills, cranes, ducks, and many unknown species. In the Tchad, Lotra, and other districts the fish are captured, dried, and exported in large quantities to Fezzan and the countries beyond the Niger. Flies and mosquitoes swarm in the marshy, and locusts in the dry districts, and in the woodlands insect life is represented by myriads of termites and some very large species of bees, wasps, and ants, besides beetles and butterflies in considerable variety.

The term Khad es Sudan is fully justified by the ethnical conditions of this region, which may be regarded as the true home of the Negro variety of mankind. Here this still everywhere forms the substratum of the population, constituting the distinct aboriginal element, in many places exclusively, in others intermingled with foreign intruders from the north and east. As far as can now be determined, these intruders belong to two separate branches of the Caucasian stock—the Hamitic and the Semitic. The Hamitic is represented by three divisions—Fulahs, Tibus, and Berbers—all of whom arrived in remote prehistoric times, the Semitic by one division—the Arabs, who arrived at various periods since the spread of Islam in North Africa. The bulk of the Arab tribes appear to have penetrated from the Nile basin through Kordofan to Dar Fur and Wadai, or from the Mediterranean seaboard through Fezzan and across the Sahara to the Tchad basin, and hence are still mostly restricted to the central and eastern districts. Owing to their later appearance and stronger racial sentiment they have kept more aloof from the surrounding populations than the Hamites, who have everywhere intermingled with the aboriginal Negro element. The result is that the present inhabitants of Sudan are of a very mixed character,—more or less pure Negro peoples predominating in the Niger basin, in Adamawa, Baghirmi, Wadai, parts of Dar Fur and Kordofan, and in the Nile basin south of 10° north latitude, half-caste Negroes and Fulahs especially in Western Sudan, half-caste Negroes and Berbers in the northern districts of Western and Central Sudan, half-caste Negroes and Tibus (Dasas) mainly in Kanem and Bornu, true Fulahs scattered in isolated groups between the Niger and Tchad basins, true Berbers (Tuaregs) in the Timbuktu and Moassur districts, true Arabs chiefly in Baghirmi, Wadai, Dar Fur, and Kordofan.

In the subjoined table of the chief Sudanese races the Negro divisions have little more than a linguistic value.

Negro and Negroid Peoples

Mandingoes. Mandinka, Malinka, and in the east Yangarawa, the dominant race between the Joliba (Upper Niger) and Kong Mountains, where their simple and harmonious speech is everywhere current as the chief medium of intercourse. The Negro type tall, very dark complexion, from coffee-brown to black, long frizzly and woolly hair, agriculturists and traders, mostly Mohammedans, whose population six to eight millions. Chief subdivision the Bombarras whose capital is Segou on the Joliba. Population 2,000,000.

Most ethnologists adopting Dr Müller's general classification, group the Fulahs with the Nubians in a separate division ("Nubio-Fulahi family") and class the Tibus as Negroes. But more recent research has shown—(1) that the Fulahs and Nubians differ fundamentally in speech and physique, the former being of Caucasian and the latter of Negro type (Krause, Rüppell) and (2) that the Tibus are not Negroes but Hamites akin to the Tuaregs of the Western Sahara, although the two languages are totally distinct (Nachtigal). The Tibu language has been described as a Negro form of speech, but this is also a mistake. It is that of the Northern Teda. From Tibu it appears to have spread southwards to Kanem and Bornu, where the Dasa, Hamar, and other dialects have been exposed to Negro influences. Had Tibu been originally a Negro language, its progress would have been thence northwards, not from the Sahara southwards.

Sonrhai or Songhai An historical race whose empire stretched in the 16th century from the northern bend of the Niger to the Atlantic and Morocco, speech of a monosyllabic type, still current in the Timbuktu district and oases of Western Sahara, population 2,000,000

Tombo, Mossi, Gurma Three little known Negro peoples west of the Niger, within the great bend, affinities uncertain, form semi-independent petty states, apparently tributary to Moassina and Gando

Auwa or Awe Large Negro nation along both sides of the Niger from Rabba to the Benue confluence, subject to Gando

Yoruba Powerful Negro people between lower Niger and Dahomey, capital Ilesin, Mohammedans pagans, and Christians (Protestant)

Batta The chief Negro people in Adamawa, now subject to the Fulahs; pagans and Mohammedans

Hausa Largest, most widespread, and intelligent of all the Sudanese Negro peoples, mainly between the Niger and Bornu, speech very musical, the chief commercial medium in Western and Central Sudan and current in parts of Tripolitania, shows distinct traces of Hamitic influences (Arauc), mostly Mohammedans

Mossi or Masa Widespread Negro family between Lake Tchad and Adamawa and stretching east to the Shari, chief subdivisions—Mandara, Margi, Logon, Gamorgu, Murgom, Kerblina, mostly pagans and uncultured

Ledina (Buduma) and **Kuri** Predatory Negro tribes in the islands of Lake Tchad, appear to be related to the Kolokos or Mekari of Logon and Bornu, nominal Mohammedans, population 30,000

Baghirni The dominant people in Baghirni cultured Mohammedans, very industrious and skilled in weavers and dyers population over a million

Alaba The chief Negro nation in Wadai, mainly in the Wara and Abachir districts, about the headstreams of the Balba

Fir or For The dominant race in Dar Fur, which takes its name from them, akin to the Nubas, chief subdivision Kunjara

Nubas Large Negro nation, Jebel Nuba, and other parts of Kordofan, the original stock of the Nubians chief subdivisions—Kargo, Kulfan, Kolah, Tumali

Ayolite Negroes Shilluk, Dinkas, Bongos, Bani A Madi (Miliin) and many others about the Bahr el-Jebel and south western tributaries of the White Nile

Funi A very mixed Negroid race, Senaar

Hamites—Pue and Afired

Tuaregs A main branch of the Berber race, dominant throughout the Western Sahara and southern steppes, powerful, especially in the Timbuktu district and on the north frontier of Bornu

Sorinka or Assuank Called also Serehull or Serrakolat *te*, "white people", half-caste Tuareg and Negro nation scattered in small communities from the Niger to the Atlantic, and numerous especially in Senegambia and Moassina, cultured Mohammedans, and active traders

Fulahs The most powerful intelligent, and widespread of all the Sudanese peoples, from their original home in Senegambia (Kia Toro Futa Jalla) have spread since the 18th century throughout Western and Central Sudan and as far east as Dar Fur, everywhere propagating Islam, overthrowing the native Haussas and other states, and founding new kingdoms in the Niger basin, in Adamawa and Central Sudan, are called Fellani by the Haussas *Fulda* by the Arabs, *Fellidia* by the Kanuri, the term meaning "fair" or "light coloured", pure type, distinctly Caucasian, regular features, long black hair brown or ruddy complexion, slim well proportioned figures, but a long nose, which presents several remarkable features shows only faint traces of Berber influence and appears on the whole to be essentially a Negro form of speech, adopted probably during residence from the remotest times in Negroland population seven to eight millions

Dasa The southern branch of the Tibus, chiefly in Kanem and northern Bornu type and speech show distinct Negro influences

Kanembu The people of Kanem, with settlements in eastern Bornu also originally Tibus, but betraying still more decided Negro influence

Kanuri The ruling race in Bornu, speech a development of the Dasa and Kanem type half-caste Tibu and Negro

Zoghawa Baele, Ennedi Mixed Tibu and Negro tribes, northern Dar Fur, originally from Borku and Wanganva, Eastern Sahara, speech akin to Dasa

Semites

Aulad Soleiman Arabs In Kanem

Aulad Rashid, Mahamid South east of Borku, and in Dar Fur

Salami, Aulad Hamid Between the lower Shari and Bahr el Ghazal

Hami, Hamid Kordofan

Kababish "Goatherds", widespread along west side Nile, from Kordofan to Dongola

Bakkara "Cowherds", south of the Kababish to left bank of Bahr el Atab

Politically Western and Central Sudan are divided into eight independent and semi-independent states, which in their order from west to east are as under—

Bambarra, divided into two nearly equal sections of the Joliba, which traverses it from south west to north east, is ruled by the Negro Bambaras of Mandingo stock. It has recently been brought under the influence of the French penetrating eastwards from their possessions on the Senegal. The capital is Sego, on the right bank of the Joliba

Moassina, Gando, Sokoto, Adamawa, the four so called "Fulah States," occupy the Niger basin between Bambarra and the Benue confluence, the whole of the Benue basin, and the region lying between the Niger and Bornu. **Moassina** (Massina) lies on both banks of the Niger from Bambarra to Kabara, the port of Timbuktu, and is peopled by Fulahs, Bambaras, and Sourhais, capital Hamda Alalu, on the right bank of the Niger, below Jenne, which is its chief trading place. Timbuktu, with surrounding district constitutes a separate territory governed by a kadri, or hereditary mayor, who lately sent an envoy to Paris for the purpose of seeking French protection against the rival Tuareg and Fulah tribes. **Gando**, so called from its capital on an eastern tributary of the Niger, stretches along the main stream southwards to the Benue confluence, including the Nife territory and part of Yoruba. The lower part is extremely fertile, abounding in cotton, indigo, rice, and all varieties of African grains. It comes within the limits of the region over which the British protectorate has recently been extended. Besides the capital, there are several large towns, such as Bida (30,000 to 50,000 inhabitants) in the north, Rabba (40,000 to 50,000), head of the steam navigation on the Niger, and a chief station on the great trade route running from Lagos on the

Guinea Coast northwards to Gando and Sokoto, Egga (8000), on the left bank of the Niger, centre of the British trade, Lokoja, facing the Benue confluence, an English factory, headquarters of an Anglican mission and seat of a Negro bishop. **Soko**, sometimes spoken of as the "empire of Sokoto," is the largest and most powerful of all the Sudanese states, stretching from Gando to Bornu, and from the Benue northwards to the Sahara (see Sokoto). In it are absorbed all the former "Hausa States," and to it Adamawa is also tributary. The inhabitants are chiefly Fulahs and Haussas, intermixed with many aboriginal Negro peoples, especially in the south and south east. The land is generally fertile, yielding rich crops of cereals, cotton, tobacco, indigo, sugar, yams, black pepper, ginger, melons. The capital and residence of the sultan is Sokoto, in the extreme north west. Other large towns are—Katsena, before the Fulah invasion a place of 100,000 inhabitants, now reduced to 7000, Kano, in Barth's time the "London of Sudan," and still with 50,000 souls (Mattienei), Wurnu (15,000), Goinbe, in the province of Calam (20,000), Yakoba, or Gari in Bahr el Jebel (150,000), Koffi Abd es Senga (30,000), in Zegzeg, a great centre of the ivory trade, and converging point of the two great caravan routes from the north (Kano) and the west (Egga). **Adamawa**, so named from its Fulah conqueror Adama, and formerly known as Fumbina, or "Southland," is ruled by a Fulah vassal of Sokoto, who keeps in subjection the Battas and innumerable other Negro peoples, it lies between Sokoto, Bornu, and Baghirni, merging southwards in the unexplored equatorial region back of the Cameroons. The capital is Yola, at the northern foot of Mount Alantika. Adamawa appears to be one of the finest and healthiest regions in Africa, splendidly diversified with lofty highlands, fertile valleys, and grassy plains, overgrown in some places with forests of bananas, baobabs, and plantains, in others yielding abundant harvests of cereals, cotton, and indigo. The horses and cattle introduced by the Fulahs thrive well on the rich pastures, and elephants abound in the woodlands.

Bornu, with **Kanem**, in the north, now reduced, and the tributary state of **Logon** in the south, completely encircles Lake Tchad, except at the south east corner, where Baghirni is wedged in between Logon and Wadai, it is mostly a flat low lying region with fertile plains yielding durrah, maize, cotton, and indigo, watered by the Komadugu, Logon, and Shari, all of which flood their banks for miles during the rainy season. The ruling race are the Kanuri, cultured but fanatical Mohammedans of mixed Tibu and Negro stock. The capital of Bornu is Kuka (50,000 to 60,000 inhabitants), near the west coast of Lake Tchad, a great centre of the Sudanese trade with the Sahara and Tripolitania, and terminus of the main caravan route from Murzuk (Fezzan) across the desert to the Tchad basin, the capital of Logon is Logon birni, residence of a vassal prince. Population of Bornu estimated at 5,000,000

Baghirni, a Negro state, since 1871 tributary to Wadai, comprises the rich and well watered plains of the lower Shari, with undefined southern limits. Capital Masena, population about 1,500,000, of whom three fourths Baghirni, the rest Kolokos, Fulahs, and Arabs

Wadai, a powerful Mohammedan state occupying the whole region between Baghirni and Kanem in the west and Dar Fur in the east, and claiming exclusive ivory and slave hunting rights in the southern (upper) Shari basin. The capital is Abesir, on a head stream of the Batha. The country is mainly a hilly plateau rising to 3000 feet above the sea, and yielding good crops of maize, durrah, durrah, cotton, indigo. Population four to six millions, chiefly Nubas and other Negroes, and numerous Arab tribes, with some scattered Baghirni, Fulah, and Kanuri settlements

Eastern Sudan, comprising Dar Fur, Kordofan, Senaar, Taka, and the Negro countries on the White Nile and its south western tributaries, respectively called the Equatorial and Bahr Gazal Provinces, belonged politically to Egypt till the rebellion of the late Mahdi. Since his death in 1885 most of these provinces appear to have lapsed into a state of anarchy and barbarism, in which few vestiges remain of the peace and order introduced by the European officers of the Khedive. The Equatorial Province, however, and the Suakin district have been exempt from these troubles, the former being still held till 1886 by the governor, Emin Bey, for the Khedive, while in the latter the natives themselves succeeded in the same year in putting down the "rebels" or party of Osman Digma. For details of Eastern Sudan, see articles NILE, NUBIA, and SLAVAL

SOULT, NICOLAS JEAN DE DIEU, duke of Dalmatin and marshal of France (1769–1851), was born at Saint Amand la-Bastide (now in department of the Tarn), on March 29, 1769, and was the elder son of a country notary at that place. He was fairly well educated, and intended for the bar, but his father's death when he was still a boy made it necessary for him to seek his fortune, and he enlisted as a private in the regiment of royal infantry in 1785. His superior education ensured his promotion to the rank of sergeant after six years' service, and in July

1791 he became instructor to the first battalion of volunteers of the Bas-Rhin. He served with his battalion in 1792, and rapidly rose to the position of adjutant-general, colonel, and chief of the staff to General Lefebvre. Soult it was who practically directed the operations of Lefebvre's division in 1794, and after the battle of Fleurus he was promoted general of brigade by the representatives on mission. For the next five years he was constantly employed in Germany under Jourdan, Moreau, Kléber, and Lefebvre. The attack of the French left at the battle of Altenkirchen, which won the day, was directed by Soult, and in 1799 he was promoted general of division and ordered to proceed to Switzerland. It was at this time that he laid the foundations of his military fame, and he particularly distinguished himself in Masséna's great Swiss campaign, and especially at the battle of Zurich. He accompanied Masséna to Genoa, and acted as his principal lieutenant throughout the protracted siege of that city, during which he operated with a detached force without the walls, and after many successful actions he was wounded and taken prisoner at Monte Cretto on 13th April 1800. The victory of Marengo restoring his freedom, he received the command of the southern part of the kingdom of Naples, and in 1802 he was appointed one of the four generals commanding the guard of the consuls. Though he was one of those generals who had served under Moreau, and who therefore, as a rule, disliked and despised Napoleon, Soult had the wisdom to show his devotion to the ruling power, in consequence he was in August 1803 appointed to the command in chief of the camp of Boulogne, and in May 1804 he was made one of the first marshals of France. When Napoleon decided to lead the troops of the camp of Boulogne into Germany, Soult took the command of the right wing, and it was by his capture of the heights of Pratzen that the great battle of Austerlitz was decided. He played a great part in all the famous battles of the grand army, except the battle of Friedland, and after the conclusion of the peace of Tilsit he returned to France and was created duke of Dalmatia. In the following year he was appointed to the command of the 2d corps of the army with which Napoleon intended to conquer Spain, and after winning the battle of Gamonal he was detailed by the emperor to pursue Sir John Moore, whom he only caught up at Coruña. For the next four years Soult remained in Spain, but it is impossible to do more than allude to his most important feats of arms. In 1809, after his defeat by Sir John Moore, he invaded Portugal and took Oporto, but, deluded by the idea of becoming king of Portugal, he neglected to advance upon Lisbon, and was eventually dislodged from Oporto by Sir Arthur Wellesley. After the battle of Talavera he was made major general of French troops in Spain, and on 12th November 1809 won the great victory of Ocaña. In 1810 he invaded Andalusia, which he speedily reduced, with the exception of Cadiz. In 1811 he marched north into Estremadura, and took Badajoz, and when the Anglo-Portuguese army laid siege to it he marched to its rescue, and fought the famous battle of Albuera (16th May). In 1812, however, he was obliged, after Wellington's great victory of Salamanca, to evacuate Andalusia, and was soon after recalled from Spain at the request of Joseph Bonaparte, with whom he had always disagreed. In March 1813 he assumed the command of the 4th corps of the grand army and commanded the centre at Lützen and Bautzen, but he was soon sent, with unlimited powers, to the south of France to try and repair the damages done by the great defeat of Vittoria. His campaign there is the finest proof of his genius as a general, although he was repeatedly defeated by the English under Wellington, for his soldiers were but raw conscripts, while those of Wellington were the veterans of many campaigns.

Such was the military career of Marshal Soult. His political career was by no means so creditable. After the first abdication of Napoleon he declared himself a royalist, received the order of St Louis, and acted as minister for war from 3d December 1814 to 11th March 1815. When Napoleon returned from Elba Soult at once declared himself a Bonapartist, and acted as major-general to the emperor in the campaign of Waterloo. For this conduct he was exiled, but not for long, for in 1819 he was recalled and in 1820 again made a marshal of France. He once more tried to show himself a fervent royalist and was made a peer in 1827. After the revolution of 1830 he made out that he was a partisan of Louis Philippe and constitutional royalty, and served as minister for war from 1830 to 1834, as ambassador extraordinary to London for the coronation of Queen Victoria in 1838, and again as minister for war from 1840 to 1844. In 1848, when Louis Philippe was overthrown, Soult again declared himself a republican. He died at his castle of Soultberg near his birthplace in 1851.

SOUND See ACOUSTICS

SOUNDING to ascertain the depth of the sea has been practised from very early times for purposes of navigation, but it is only since the introduction of submarine telegraphy that extensive efforts have been made to obtain a complete knowledge of the contour of the ocean bed. As early as the middle of last century a few deep soundings were recorded in various parts of the world. Ellis made one in 1749 of 891 fathoms off the north west coast of Africa. But these early results must be accepted only with great caution, for the methods then in use were not such as to ensure accuracy at any depth greater than a few hundred fathoms. Sir John Ross, the arctic explorer, was much in advance of his times as regarded such investigations, he invented a "deep-sea clamm" for bringing up a portion of the bottom, and on September 1, 1819, in Possession Bay, made a successful sounding at a depth of 1000 fathoms, which is especially memorable because it was clear, from the organisms which came up entangled in the line, that animal life existed at that depth.

The operation of sounding is readily performed in shallow water by letting down a weight attached to a cord, which is marked off into fathoms by worsted tucked under the strands, the tens and hundreds being indicated by different colours. The bottom of the weight usually presents a hollow, which is filled with tallow, so that a portion of the material from the bottom may be brought up and give an indication of its nature. Some times a valved cavity is used instead of the tallow. It is easy to see that the longer the line let out the greater will be its friction in passing through the water, the more slowly the weight will descend, and the slighter will be the shock transmitted to the upper extremity when it reaches the bottom, indeed, at what are now considered very moderate depths this becomes quite imperceptible, hence in deep sea sounding the line is carefully watched as it runs out, and the time each 100 fathom mark enters the water is noted down. Owing to the increasing friction these intervals gradually lengthen, but any sudden increment indicates that the bottom has been reached, for it shows that the weight has ceased to act, and that further descent of the line is due merely to its own gravitation. For instance, in one of the "Challenger" soundings, with a line 1 inch in circumference, and with a weight of 4 cwt. attached, the time occupied in descending from 2900 to 3000 fathoms was 2 m 10 s, from 3000 to 3100 fathoms 2 m 13 s, and from 3100 to 3200 fathoms 3 m. 14 s, this sudden increase showing that the bottom had been reached in the interval.

Furthermore, the weight required to sink a line in deep

water with sufficient rapidity for purposes of accurate observation is so great that it is found impracticable to bring it up again without putting an undue strain upon the rope or seriously prolonging the operation. Hence in 1854 Brooke, an American, devised an apparatus by which the weight was detached when it reached the bottom and only a small tube containing a sample of the bottom was brought up. This was in fact a modification of an apparatus which had been devised by Hooke in the 17th century, he made an arrangement in which a light sphere was sunk by a heavy weight, but was liberated on reaching the bottom,—the depth being then deduced from the time which elapsed between the sinking of the globe and its reappearance at the surface. Of the various modifications of Brooke's sounding machine, perhaps the most famous is that constructed by the blacksmith of H.M.S. "Hydra," and commonly known as the "Hydra sounding rod." It was used on the cruises of the "Lightning" and "Porcupine" and during the earlier part of the "Challenger" expedition. This apparatus is shown in fig 1, where AB is the rod, terminating in a tube below so that it may bring up a sample of the bottom, the weights F fit loosely round it and are supported by the wire E which passes over the stud D, where a spring presses against it, the strength of which is so adjusted that it is unable to displace the wire as long as the strain of the weights

Fig 1

Fig 2

Fig 3

Fig 4

Fig 5

is upon it, but so soon as this is relieved by their resting on the bottom the wire is thrust off the stud, and

when the line is hauled in the weights and wire are left behind.

An improved apparatus has recently been invented by Mr J Y Buchanan, and used by him on board the telegraph ships "Dacia" and "Buccaneer," which can be used either in shallow or deep water, and has the advantage of bringing up samples both of the water and of the mud from the bottom. It consists of a hollow cylinder A, fig 2, at the top and bottom of which are india rubber valves H, K, opening upwards, so that water passes freely through them during the descent but is retained as soon as a plug of mud occupies the tube B. The weight EE which surrounds the cylinder is supported by a wire F passing over a peculiar hook D, shown separately in figs 3, 4, 5, when sounding in shallow water it is not necessary to detach the weight, and the wire is therefore placed as in fig 3, when working at greater depths the wire rests on the other side of the hook, as in fig 4,—the result being that on the bottom being reached it falls into the upper part of the notch, fig 5, and continues to press the tube into the mud, but when hauling up commences the wire slips out altogether and the weight is left at the bottom. A valve L, M, N is sometimes used to retain the sample of the bottom.

At the present time deep sea sounding is extensively practised for telegraphic purposes, and is almost entirely conducted by means of wire instead of rope, a method introduced by Sir William Thomson. The friction of the wire in passing through the water is of course very much less than that of rope, and hence it runs out and can be hauled in much more rapidly, a smaller sinker may be used, and in very many instances it can be recovered. It is customary in sounding for cables to make very frequent observations (once in from 1 to 50 miles), for it is found that the laying can be accomplished with much less risk of accident if the contour of the ocean bed be accurately known. The saving of time by the use of wire is very considerable, but the advantage is not so obvious in running out as in hauling in, because a heavier weight is used to increase the rate, this of course involving a loss of iron sinkers. For instance, an apparatus similar to that mentioned above as being used by the "Challenger" took on an average 24 m 22 s to sink 2000 fathoms, whilst in a recent sounding by the "Albatross" the weight ran out 2000 fathoms in 20 m 30 s and was hauled in in 21 m 0 s,—a rate which would have been quite unattainable by the aid of rope. The saving in the matter of sinkers is by no means inconsiderable, instead of 3 or 4 cwt, only 50 to 60 lb are used, and Sigsbee has calculated that this difference is sufficient to pay for any extra loss there may be by the breaking of the wire. Captain Magnaghi of the Italian navy and Captains Sigsbee and Belknap of the American Survey have successfully developed the method of sounding with wire, and owing to its use the last mentioned officer was able to survey the route from San Francisco to Japan, doing all his sounding by hand, which would have been quite impossible had hempen rope been used. When soundings are made for scientific purposes it is customary to ascertain the temperature, both at the bottom and at intermediate depths, by a thermometer of special construction.

"Challenger"* (London 1887), Sigsbee, *Deep-Sea Sounding and Dredging* (Washington 1887), *Wille's Norwegian North Atlantic Expedition* pt iv "Apparatus" and how a "Norwegian North Atlantic Expedition" (Edinburgh 1887) and for an improved apparatus used on board the "Tallman" *La Nature* xlv p 111 for 1876-78. Also the annual Reports of the U.S. Fish Commission (W.F. 110).

SOUTH, ROBERT (1633-1716), one of the wittiest of English divines, was the son of a London merchant, and was born at Hackney, Middlesex, in 1633. He was educated at Westminster school, whence in 1651 he was elected to Christ Church, Oxford. He became B.A. in 1654, and the same year wrote several Latin verses to congratulate Cromwell on concluding peace with the Dutch, which were published in a collection of university poems. The following year he published a Latin poem, entitled *Murea Incantans*. After commencing M.A. in 1657 he was in the habit before obtaining orders in 1658 of preaching as the champion of Calvinism against Socinianism and Arminianism. He also at this time showed a leaning to Presbyterianism, but on the approach of the Restoration his views on church government underwent a radical change.

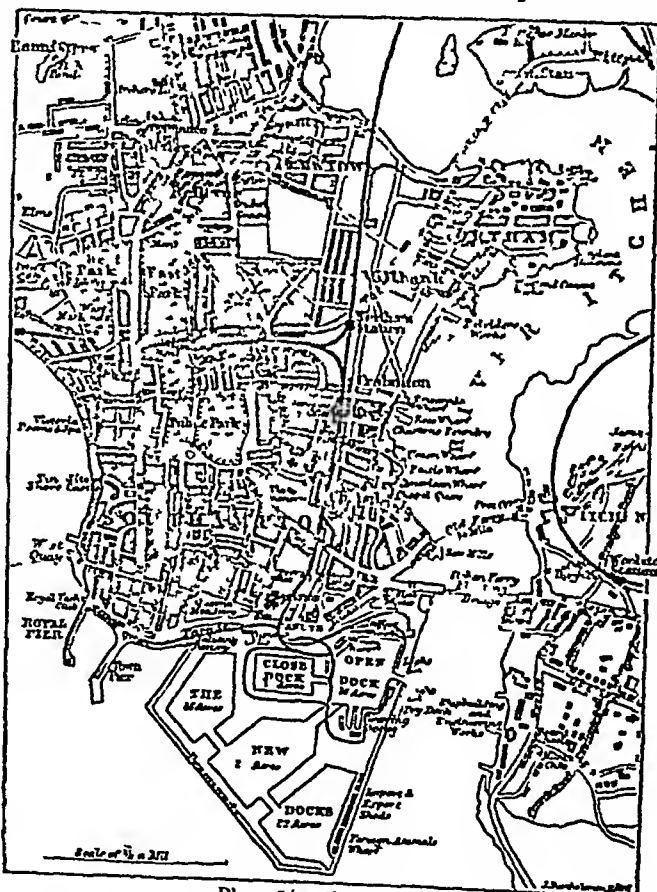

went a change. In fact he adhered successively to the triumphant party as represented by Cromwell, Charles, James, and William, and there are substantial grounds for the assertion of Anthony Wood that he was much indebted for his preferments to his zeal for "the powers that be." On 10th August 1660 he was chosen public orator of the university, and in 1661 domestic chaplain to Lord Clarendon. In March 1663 he was made prebendary of Westminster, and shortly afterwards he received from his university the degree of D.D. In 1667 he became chaplain to the duke of York. He was a zealous advocate of the doctrine of passive obedience, and also strongly opposed the Toleration Act, declaiming in unmeasured terms against the various nonconformist sects. In 1676 he was appointed chaplain to Lawrence Hyde (afterwards earl of Rochester), ambassador extraordinary to the king of Poland, and of his visit he sent an interesting account to Dr Edward Pocock in a letter, dated Danzig, 16th December 1677, which was printed along with South's *Posthumous Works* in 1717. In 1678 he was promoted by the chapter of Westminster to the rectory of Islip, Oxfordshire. Owing, it is said, to a personal grudge, South in 1693 published *Animadversions on Dr Sherlock's Book, entitled a Vindication of the Holy and Ever Blessed Trinity*, in which the views of Sherlock were attacked with much sarcastic bitterness. Sherlock, in answer, published a *Defence* in 1694, to which South replied in *Tritheism Charged upon Dr Sherlock's New Notion of the Trinity, and the Charge Made Good*. The controversy was carried by the rival parties into the pulpit, and occasioned such keen feeling that the king interposed to stop it. During the greater part of the reign of Anne South remained comparatively quiet, but in 1710 he ranked himself among the partisans of Sacheverell. He died 8th July 1716, and was buried in Westminster Abbey.

The style of South is vigorous, pungent, and brilliant, though tending to exuberance. His sermons are strongly practical, but his theory of life is not ascetic. His wit generally inclines towards sarcasm, and it was probably the knowledge of his quarrelsome temperament that prevented his promotion to a bishopric. If he sacrificed principle to his desire for preferment, his ambition was not of a sordid kind, for he was noted for the extent of his charities. He published a large number of single sermons, and they appeared in a collected form in 1692 in six volumes, reaching a second edition in his lifetime in 1715. His *Opera Posthuma Latina*, including his will, his Latin poems, and his orations while public orator, with memoirs of his life, appeared in 1717. His *Works* were published with a memoir by the Clarendon press in 1827, and have been several times reprinted. The contemporary notice of South by Wood in his *Athenæ* is characterized by a strongly hostile tone, partly to be explained by a criticism of South at Wood's expense.

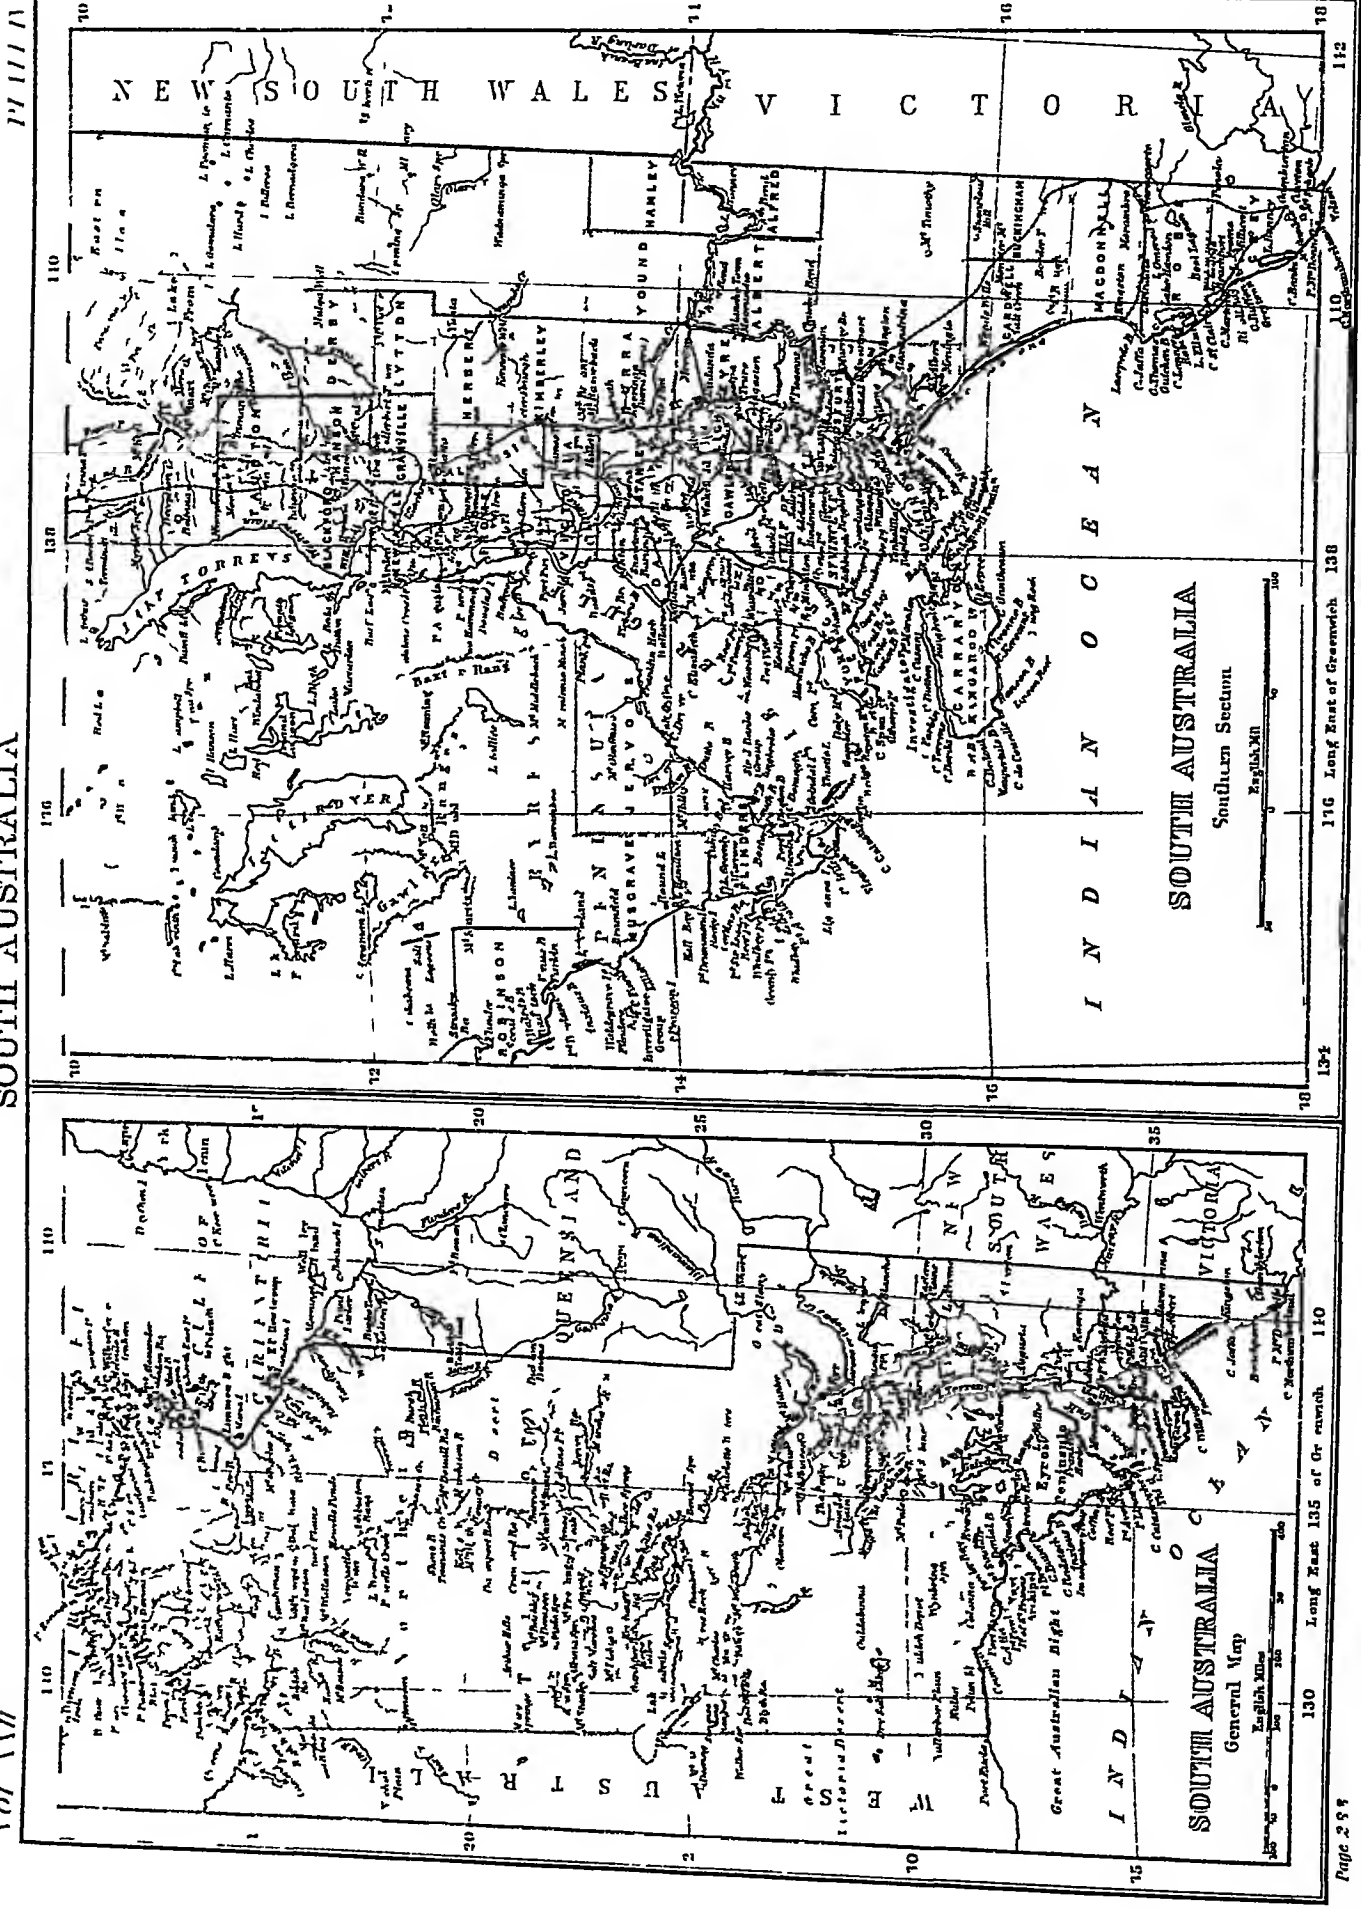

SOUTH AFRICAN REPUBLIC. See TRANSVAAL.

SOUTHAMPTON, a municipal and parliamentary borough, which gives name to Hampshire, or the county of Southampton, and one of the principal seaports on the south coast of England, is beautifully situated at the head of Southampton Water, forming the mouth of the Test, on a sloping peninsula, bounded on the east by the Itchen, at the terminus of the South Western Railway, 79 miles south-west of London, 13 south-south-west of Winchester, and 24 west-north-west of Portsmouth. Southampton is also a county of itself,—the county of the town of Southampton. It preserves much of its antique appearance, but, although in the older parts the streets if picturesque are narrow and irregular, it may still claim the distinction it enjoyed in Leland's time of ranking "as one of the fairest that is in England," handsome and spacious shops lining the principal streets, while the suburbs are studded with numerous villas and mansions embosomed in woods. There are still considerable remains of the old town walls built in the time of Richard II., the most remarkable being a portion of the west walls, with an

areado on its exterior face. Four of the seven gates are comparatively well preserved—North or Bar Gate, South Castle Gate, Westgate, and Blue Anchor Gate. The finest of these is Bargate, in a room above which is the ancient Guildhall, where the quarter sessions are held. The representations of Sir Bevis of Hampton and the giant Asepart which formerly stood on each side have recently been obliterated. The castle, originally a Saxon fortress, and rebuilt when the walls were erected, was partly demolished in 1650. After its rebuilding had been begun by the marquis of Lansdowne in 1805, it was sold, and in 1818 the site was parcelled out for building plots. In the vicinity of the castle there are some houses of very ancient date, including King's House (Early Norman). The two old churches, St Michael's (originally Norman about the date of 1080) and Holyrood, have been in a great degree modernized, the former contains a beautiful Byzantine font and a monument to Sir R. Lyster, chief-justice in the 16th century. The French chapel of St Julien, originally attached to the hospital of God's House, founded by Henry VIII for eight poor persons, is of Norman architecture, it contains the burial place of the

earl of Cambridge, Lord Scrope, and Sir Thomas Grey, who in 1415 were executed outside the Bargate for conspiring against Henry V. Among the modern public buildings are the Watts memorial hall, erected in 1876 at a cost of £8000, the municipal office, occupying the old audit-house, the custom-house, the philharmonic hall, the assembly rooms, the county court-house, the corn exchange and chamber of commerce, and two theatres. The educational institutions include the Hartley Institution, founded by bequest for the advancement of natural history, astronomy, antiquities, and classical and Oriental literature, and now embracing a library, reading room, museum, art gallery, laboratories, and schools of science and art associated with South Kensington, the Edward VI grammar school,

founded in 1550, and reorganized in 1875, and Alderman Taunton's school, founded in 1752, and lately remodelled. The school board was established in 1871. The benevolent and charitable institutions are numerous, embracing the dispensary (1809), the royal South Hants infirmary (1838), the female orphan asylum, the homoeopathic dispensary (1873), St Mary's cottage hospital (1873), and the Palk memorial home (1876). To the north of the town is Southampton Common, formerly part of the manor of Shirley, and adjoining the town to the north of Above Bar Street is the Public Park, prettily laid out and containing statues of Lord Palmerston, Dr Watts, and Mayor Andrews. The town is supplied with water partly from artesian wells and partly from reservoirs. The population of the municipal borough (area 2004 acres) in 1871 was 53,741, and in 1881 it was 60,051. In 1885 the area of the parliamentary borough, formerly coextensive with that of the municipal borough, was extended to include the parish of Millbrook, the ecclesiastical district of the Holy Saviour, Bitterne, the parish of St Mary Extra, and the detached portion of Hound included within St Mary Extra. The population of this area in 1881 was 84,384. It is represented by two members.

The importance of the port dates from the Norman Conquest, and was originally due to its relation to Winchester. It had a considerable trade in wine as early as 1152, and from Queen Mary it obtained a monopoly in the importation of sweet wines from the Grecian islands. With Venice and Italy it had a large trade as early as the 14th century, and in the subsequent century it had a connexion with Newfoundland, while its Channel trade and its shipbuilding were also of importance. About the end of the 16th century its trade had, however, begun to decline, and the visitation of the plague in 1665 tended still further to aid its retrogression. Some improvement took place in its prospects by the creation of a Pier and Harbour Commission in 1803, and the erection of the Royal Victoria pier in 1831 was a further step towards prosperity, but its modern trade really dates from the opening up of railway communication with London in 1840. It possesses one of the finest natural harbours and has the advantage of a double tide, a second high tide occurring two hours after the first. While largely dependent for its import trade on its connexion with London and its easy communication with France, it has become an outlet for the manufactures of the midland and northern towns. Its great tidal dock, completed in 1843 at a cost of £140,000, has an area of 16 acres with a depth of 18 feet at low water, and the inner dock, completed in 1851, an area of 10 acres and a depth of 28 feet. Two other docks embracing an area of 50 acres are being constructed. There are also four dry docks, capable of receiving vessels of the largest tonnage at all tides. Within recent years the port has lost the overland trade between London and India by the removal to London of the headquarters of the Peninsular and Oriental Steam Navigation Company. At present it is the headquarters of the Royal Mail Steam Packet Company for the West Indies and the Pacific (*via* Panama) and for Brazil and the River Plate, the Union Line for the Cape of Good Hope, Natal, and East Africa, and the London and South Western Railway Company's steamers to the French coast. Steamers also sail regularly for Ireland and various ports on the west coast of England, and the steamers of the North German Lloyd Company touch at the port on the way to and from New York, and also to and from Asiatic and Australian ports. The total number of vessels that entered the port in 1876 was 7840 of 1,201,301 tons, of which 3780 with a tonnage of 201,434 were sailing vessels, and 4060 with a tonnage of 999,867 were steamers. The number that cleared in the same year was 8047 of 1,174,365 tons, of which 3994 (196,064 tons) were sailing vessels, and 4053 (978,301 tons) were steamers. In 1885 the number of vessels that entered the port was 9768 of 1,539,357 tons, of which 3456 (175,900 tons) were sailing vessels, and 6312 (1,363,457 tons) were steamers. The number that cleared in the same year was 9641 of 1,523,759 tons, of which 3350 (182,688 tons) were sailing vessels, and 6291 (1,341,071 tons) were steamers. Since 1845 the trade has increased more than tenfold, although within recent years the port has suffered from the prevailing dullness. The total value of imports and exports in 1845 was £1,475,000, in 1880 the value of the imports was £9,205,183 and in 1884 it was £7,514,354, for these last years the value of the exports of United Kingdom produce was £9,306,326 and £6,909,072, while the value of the exports of foreign and colonial produce and manufactures in 1882 was £1,589,652 and in 1884 £1,150,954. Among the principal imports are cocoa, coffee, corn (including maize), apples, provisions (especially butter, eggs, and potatoes from France and the Channel

Isles), rum and brandy, sugar, wine, wool, and rags. Among the principal exports of the produce of the United Kingdom are apparel, cotton goods, leather, linen goods, machinery, copper and iron goods, woollen and worsted goods. The number of ships built at the port in 1885 was 19, of 17,876 tons burden.

The Roman station of Clausentum was situated at Bitterne on the opposite side of the Itchen, where extensive Roman remains have been found. The present town was founded by the West Saxons, probably soon after their landing under Cerdic and Cyric on the shores of Southampton Water in 495. The name Hantun seiro (Hamptonshire) occurs in the *Saxon Chronicle* under date 755, and Hantun is first mentioned separately in 837. The prefix "South" was probably added after the annexation of Wessex to Mercia in 920, to distinguish it from the Hampton in Mercia afterwards called Northampton. The town was frequently ravaged by the Danes in the 9th and 10th centuries. Canute, after his establishment on the throne, made it his occasional residence, and Southampton beach is reputed to have been the scene of his rebuke to the flattery of his courtiers, by the demonstration of his powerlessness to control the waves. Southampton is mentioned in Domesday as Hantune. It possessed a mint as early as 925. It was frequently visited by successive monarchs from the time of Henry I. In 1338 it repulsed an attack of the French and Genoese. In 1415 it was the rendezvous of the army of Henry V for France, and during his stay in the town he detected the conspiracy against him of the earl of Cambridge, Lord Scrope, and Sir Thomas Grey, who were executed outside the Bargate. In 1512 the marquis of Dorset embarked from the port with 10,000 men to the aid of Ferdinand of Spain against France, and in 1522 the earl of Surrey set out from it with a large fleet to escort Charles V. Queen Elizabeth held a court at Southampton in 1569. On account of the outbreak of the plague in London in 1625 the council was transferred by the king to Southampton, where on the 7th September a treaty was signed with the United Provinces. The town received its first charter from Henry II, and a charter of incorporation from Henry VI in 1445 under the style of "mayor, bailiff, and burgesses." This charter was somewhat modified by that granted by Charles I which remained the governing charter till the passing of the Municipal Act. The corporation act as the urban sanitary authority. The town first returned members to parliament in 1295. Among eminent persons connected with Southampton are Dibdin the song writer, Bishop Peacocke, Thomas Fuller, and Dr Watts.

See *History of Southampton*, by J. Sylvester Davies 1883.

SOUTH AUSTRALIA, which lies between 129° and 141° E long, has New South Wales and Victoria on the E., Western Australia on the W., and the Southern Ocean on the S. Originally its northern line was 26° S lat., but by the addition of the Northern Territory, or Alexandra Land, the area has been extended from 380,070 square miles to 903,690, and the northern border carried to the Indian Ocean. The length is therefore from lat 38° S to 11° S, nearly 2000 miles. Being much more northern and less southern than the neighbouring colony, its present designation is incorrect in point of fact.

The southern coast-line shows two large gulfs, Spencer and St Vincent,—the first 180 miles long, the other 100. Spencer Gulf is open to the ocean, while St Vincent Gulf is partly shielded by Kangaroo Island, with Investigator Straits as its westerly entrance and Backstairs Passage for an easterly one. Yorke Peninsula separates the two gulfs. Port Lincoln and Sleaford Bay are at the south west of Spencer Gulf. On the western side of Eyre Peninsula—the land westward of Spencer Gulf—are the following bays—Coffin, Anxious, Venus, Streaky, Denial, and Fowler. The junction of South and Western Australia is on the Australian Bight. Encounter Bay is on the Victorian side, with Lacedpede, Guichen, Rivoli, and Macdonnell Bays to the south east. Flinders, Investigator, and Nuyt Islands are south-west. Cape Jervis is at the eastern entrance of St Vincent Gulf, Spencer at the western. In Northern Territory are Melville, Adam, Arnhem, and Raffles Bays, Van Diemen's Gulf, Port Essington, and Port Darwin (lat 12° S). The Gulf of Carpentaria divides the territory from Cape York Peninsula of Queensland. Melville, Bathurst, and Groote Eylandt are northern islands. The ranges of hills are few, rarely reaching 3000 feet. One chain runs north from Cape Jervis. Flinders range has Brown and Arden, 3000 feet. Lofty,

near Adelaide, is 2330 feet. Volcanic cones, as Gambier and Schanck, are south east, near Victoria. In general the country is level, where not slightly undulating. It is far from being well watered, especially to the westward and in the interior. The Murray, passing through Lake Victoria, had previously received most of the drainage of the three eastern colonies. The Torrens flows by Adelaide. Few streams reach the ocean. Cooper's Creek drains part of Western Queensland. The Indian seas receive the Alligator, Liverpool, Roper, Macarthur, Daly and Victoria rivers. Albert and the Coorong are lakes at the Murray mouth. The depressed area northward contains Lakes Torrens, Eyre, Gairdner, Blanche, Hope, and Amadeus. The overland telegraph to Port Darwin passes mostly through an ill watered country, with oases around springs. The population, 330,000, is principally within 100 miles of Adelaide, the capital, in lat. 35° S. The leading places north of Adelaide are Gawler, 25 miles, Barossa 38, Kapunda 49, Angaston 51, Port Wakefield 60, Clare 90, Koorunga of Burra Burra 100, Moonta 100 north west, Kadina 96 north west, Blyth 100, Morgan or North West Bend 105, Broughton 150, St Petersburg 154, Port Pirie 155 north-west, Port Augusta 240 north-west, Colton 320, Blinman 350. To the east are Barker 21, Eclunga 23, Nairne 25, Kingston or Port Caroline 170 south east, Narracoorte 220, Penola 250, Gambier 290, Macdonnell 304. Lincoln is 210 west. Adelaide Port is 7, Glenelg 7, Brighton 10, Willunga 30 south, Goolwa, the Murray port, is 60 south. Palmerston of Port Darwin is the chief town of Northern Territory, Southport is 25 miles south of it. Other settlements are inland mining townships. There are 36 counties, 4 pastoral districts, 23 municipalities, and 112 district councils in South Australia proper.

Climate.—Excepting Western Australia, this is the driest portion of the island continent. The rain clouds from the Pacific or the Indian Ocean have little store left on reaching the South Australian districts. The north-west summer monsoons favour the northern coast-lands, though the rains penetrate but few miles inland. The trade-winds bring only dry blasts from the Queensland side. A large proportion of the south western shore has a very partial deposition, and even the southern Yorke Peninsula, laved by two great gulfs, seldom shows any surface water. The conflict between the polar and equatorial currents occasionally throws down rain in the interior, though many a thunder-storm fails to let fall more than a few drops. But the south eastern coast catches a fair amount of rain from the western breezes off the Southern Ocean. The settled districts have winter rains, when Adelaide plains are transformed from parched sterility to luxuriant vegetation. The average annual rainfall there is but 20 inches, with an evaporation of three times that amount. In 1885 (a dry year) Adelaide had only 16 inches. In some years only 5 inches have fallen, even on parts of the sea shore. The interior, however, has been known to have extensive floods after sudden storms. The northern coast, as at Port Darwin, has from 50 to 70 inches, though for several months without a shower. The heat is considerable during the dry summer time, though cold is felt severely on winter mornings and nights, even in the tropics, when a dozen degrees of frost may be followed in a few hours by a temperature of 80° or 90°.

The health conditions of the colony are but little inferior, except in Adelaide and Port Darwin, to those ruling in Tasmania and New Zealand, which are so much cooler and wetter. Dry heat is never so prejudicial as a moist heat. A raging hot wind from the north and north west, to which Adelaide is so unpleasantly exposed, is trying to young children, though it never brings noxious

gases. On the contrary, when passing over eucalyptus forests it brings down health giving airs, in spite of 160° in the sun, or even 120° in the shade. Diarrhoea may trouble in summer, and catarrh in winter, but, with a birth-rate of 39 in the thousand and a death rate of from 12 to 17, South Australia stands more favourably than England in relation to health. Recently, several townships had for the year but seven deaths in the thousand, exhibiting a freedom from mortality three times greater than London. The death-rate of the colony during 1885 was only 12.48 to the thousand, while the birth-rate was 37.70. One-third of the deaths were in Adelaide. Reports from the tropical Northern Territory speak of fever and ague, especially among imprudent gold miners.

Geology.—The few mountain ranges scattered throughout the colony were once, in all probability, but islands rising in a mediterranean sea that connected the Indian Ocean and Java Sea with the Southern Ocean. Over at least the southern half of South Australian territory the water flowed in Tertiary times. The climatic effect of such an archipelago of islands must have been very different from what now is realized in that region. The rise of the country displayed that vast extent of arenaceous limestone forming the southern coast floor, and extending westward hundreds of miles in Western Australia, and far eastward in Victoria. The south coast is still rising. The Murray cuts its channel through this vast coralline formation. According to the Rev J. Tomison Woods, the newer Pliocene is near Adelaide, while the older is at Mount Gambier. The Murray cliffs are Upper Miocene, and the Murray flats are Lower Miocene. He finds little or none of Eocene. Flint bands occur in this limestone, particularly at Gambier. The Biscuit country, south east, has flat limestone concretionary cakes on the surface, more or less rounded. Beds of sand cover large areas of the recent rock. Caves abound in the Gambier district, provided with stalactites and stalagmites. Subterranean rivers flow through some of the caverns, and are occasionally reached by natural sloping wells. Gambier exhibits much Bryozoa limestone. Its 40 species and 16 genera of *Polysora* are in Lower Crag. The coral limestone there has extensive flint bands. *Foraminifera* are of many kinds, some of the Rhizopoda are still existing in Australian waters. Sharks' teeth and large nautilus are frequently met with. Most fossils are in casts, except *Pecten*, *Bryozoa*, *Echini*, &c. The Murray cliffs mark the remains of an extensive formation, since largely denuded. The Gambier deposits prove the presence of an ancient deep sea, when little of Australia, as we now perceive it, had any existence. The South Australian ranges are generally of Primary order, the Silurian formation being often pierced or flooded by igneous rocks, which have transmitted the strata. While granites and granitoids are in great masses, the basalts and greenstones of a later age are not wanting in the ranges. The Primary rocks are observed, also, in Eyre Peninsula, Port Lincoln, the central central districts, and very prominently in the Northern Territory. Flat topped sandstone hills prevail northward. Westward and south eastward the Tertiary rests on a granite floor. Eastward there is the same Primary presence, with crystalline mountains developing silver mines just over the border. Metamorphic rocks, rising amidst Tertiary beds, are strong in Yorke Peninsula, producing much copper. The tablelands are of horizontal sandstone, often on spiriferous limestone. Desert sandstone may be Miocene. Near the Victorian boundary, in the south east corner of South Australia, recent volcanic action is apparent. Several of the lakes there were once craters. The deep Blue Lake, or Devil's Inkstand, occupies the centre of Mount Gambier. The banks are nearly 300 feet high, and are formed of lavas and volcanic ashes. Cinder walls are detected, and other varieties of volcanic products. Several smaller cones surround the great mount. The country itself is of the usual Tertiary limestone, more or less covered with ashes. Mount Schanck, between Gambier and the sea, is known as the Devil's Punchbowl. This cone of lava has an empty crater 200 feet deep. Gambier and Schanck are landmarks to passing mariners. Among the fossil forms in Tertiary Pliocene strata are those of the huge *Diprotodon*, a marsupial vegetable feeder 16 feet in height, with gigantic kangaroos, emus, wombats, &c.

Minerals.—South Australia, though without coal, was the first Australian colony to have a metallic mine, and the first to possess a gold mine. In 1841 the wheel of a dray, going over a hill near Adelaide, disclosed to view silver lead ore. In the midst of this bad times in 1843 the Kapunda copper mine was found. In 1845 the wonderful Burra Burra copper was first wrought. The land, 10,000 acres, cost £10,000, and for several years the dividends to shareholders were 800 per cent. per annum. The first colonial mineral export was 30 tons of lead ore, value £128, in

1843 The copper declined as prices fell. It was £322,983 in 1885, when rates were £50 a ton, but £762,386 ten years before with over £90. In 1886 most of the mines were closed. Between 250 and 400 miles north of Adelaide a very rich copper district exists. Lead is very abundant. Manganese, nickel, bismuth, antimony, and silver have been mined. Tin is seen in granitic places. Iron occurs in almost all formations and in all conditions. There is abundance of hematite, micaceous, bog, and other ores rich in the metal. Talisker and other mines paid in silver. The wonderful Silverton, of Barrier Ranges, in a desert, is just outside the boundary, though 300 miles only from Adelaide while 600 from Sydney. Gold was got from a quartz vein at the Victoria mine, near Adelaide, as early as 1846, but did not pay the company. Partial gold working has been conducted at Echunga, &c., in southern hills. There are rich alluvial and quartz gold mines in Northern Territory, at from 100 to 150 miles south of Port Darwin. For the year 1884 the yield was £77,935. Of 1349 miners 1205 were Chinese. Gold is now worked at Waukarunga, 225 miles north of Adelaide. Copper, tin, and silver are found in Northern Territory. Among other minerals asbestos, roofing slates, and fine marbles may be named. Some forty years ago precious stones, especially garnets and sapphires, were gathered in the Barossa Hills. Carbonaceous material is found at the Coorong, &c., yielding 50 per cent of oil. Lake Eyre has a rude coal. Kapunda marble quarry is a success. In 1885 there were 16,493 acres leased for minerals. The value of minerals exported in 1885 was £838,132.

Agriculture—This is essentially an agricultural colony. In its first establishment, farming was intended as the main occupation. The land was cut up for sale into eighty acre lots with the view of settling the people on arrival, and concentrating them, instead of having them scattered as in the neighbouring colonies, in which pastoral pursuits completely dwarfed the farming industry. Thus wise provision made the colony for years the supplier of breadstuffs to Sydney, Melbourne, Brisbane, Perth, and Auckland. As neighbours became wheat producers, Adelaide merchants had to seek markets in Natal, Mauritius, the Cape, or even Europe. At all times the state has lent every assistance to agriculture. As the colony suffers more from drought than anything else, public reserves are constructed and artesian wells are sunk. Forest culture has especially attracted Government attention. Reforesting and the establishment of nurseries for the trees, fruits, and vegetables of other lands go hand in hand. Forest reserves already amount to 150,000 acres. Hundreds of thousands of trees are annually planted.

The land system, sound at the beginning, has been repeatedly amended, especially with a view to the advancement of pastoral interests. Instead of cash sales, as formerly, conditional purchases may be made, extending over a long period, subject to conditions of residence and cultivation. At the end of 1884 only ten million acres had been purchased. There were, however, 53,000,000 acres enclosed, chiefly for pasturage, and 2,785,190 under cultivation. The crop for March 1885 was as follows—wheat, 1,942,653 acres, fallow, 450,536, hay, 308,429, artificial grasses, 23,217, barley, 15,697, lucerne, 8649, oats, 7264, orchard, 5825, potatoes, 5066, peas, 4601, vineyard, 4590. The culture indicates a warm and dry climate, different from New Zealand or the tropical coast of Queensland. The product of South Australian fields is so much smaller per acre than in any of the neighbouring colonies that only an open level country of cheap land, with effective machinery at moderate cost, could be managed at a profit. Going northward from Adelaide the country becomes too dry for roots, and then too precarious even for wheat. The country of Adelaide is very favourably placed for vineyards, oliveyards, and orchards. About half the olive trees and a third of the almond trees are there. Of 3,704,107 grape vines in the colony, Adelaide county had 2,158,468, and Light, in the neighbouring hills, had 860,356. There were in 1884 478,535 gallons of wine made. The commissioners lately reported that the light white wines kept sound and good, while full bodied red wines continue to improve with age. The Water Conservation Department is of great service to agriculture. Tropical cultivation receives some attention already in Northern Territory. The Chinese raise rice crops, there being heavy rains near the coast. Daly river has excellent soil and climate for sugar and coffee.

The pastoral progress has been considerable, notwithstanding want of moisture. In 1885 there were 1528 leases over 214,916 square miles, besides 257 annual leases with 11,214 square miles. There were then 168,420 horses, 389,726 cattle, 163,807 pigs, 6,696,406 sheep (twenty sheep per head of population). Of these the settled counties had 151,058 horses, 179,206 cattle, and 4,995,394 sheep. In Northern Territory, with 136,000 cattle, there were in December 1885 6000 horses and 40,000 sheep, that country, excepting in the dry interior, being unfitted for wool-bearers. The total export of wool grown in South Australia had only the value of £1,671,775 in 1885. The prices obtained were a fourth less than ten years before. The rabbit pest is felt as seriously in pastoral as in agricultural operations. Kangaroos are far less troublesome to stockholders than in Queensland. Where water can be procured by dams, reservoirs, or wells stock can be kept,

since, where the grass fails, cotton bush and various saline plants supply sufficient feed. An artesian well lately was sunk 1220 feet. Wool is remarkably fine there. While a South Australia merino has 2720 serrations to an inch of wool, a Leicester sheep has but 1850.

Fauna—South Australia is not separated from the neighbouring colonies by any natural boundaries, hence the fauna includes many animals which are also to be found in the land lying to the east and west. The northern half of the colony lies within the tropics, and possesses a tropical fauna, which is, however, practically identical with that of northern Queensland. In spite of its immense extent north and south, and a corresponding diversity in climate, the colony is poorer in animal life than its neighbours. It possesses thirty five genera of mammals. These include both genera of the order *Monotremata*,—the *Ecudna*, or spiny ant-eater, and the *Ornithomyrmecophilus*, or duck billed platypus, both of which are found also in eastern Australia and Tasmania. The other order of *Mammalia* associated with Australia, the *Marsupialia*, is well represented in South Australia. It contains seven genera of *Macropodidae* or kangaroos, including the wallaby and kangaroo rat, four genera of *Phalangistidae*, or opossums, and five species of *Dasyuridae*, or "native cats." Two genera of this family are peculiar to the region—the *Chaetocercus* and the *Antechinus*, the latter is found in the interior. It is a mouse like animal with large ears, and is remarkable for the elongation of its fore arm and hind foot and for the complete absence of the hallux. The *Phascolumys*, or wombat, one of the largest of the marsupials, is also found in South Australia, and the curious *Myrmecobius*, or ant-eater of Western Australia. This remarkable animal is about the size of a squirrel, it possesses fifty two teeth (a greater number than any known quadruped), and, unlike the other members of its order, the female has no pouch, the young hanging from nipples concealed amongst the hair of her abdomen. The *Chiropterus*, with peculiarly slender limbs and a pouch opening backwards, is found in the interior. The remaining *Mammalia* consist of the dingo, or native dog, and a few species of *Muridae*, the mouse family, and *Chiroptera*, or bats. There are about 700 species of birds, including 60 species of parrots. Of the 9 families peculiar to the Australian region, 5 are well represented, including the *Myiophagidae* (honey suckers), *Caculidae* (cockatoos), *Platycestridae* (broad tailed and grass parrots), *Megapodidae* (mound makers), and *Cassariidae* (cassowaries). The last named family is represented by the *Dromas*, or emu, which is hunted in some parts of the colony. Reptiles are fairly represented there are fifteen species of poisonous snakes. The lizards are very peculiar, South and Western Australia contain twelve peculiar genera. No tailed *Amphibia* exist in the continent, but frogs and toads are plentiful.

Flora—The plant species resemble those of the eastern colonies and Western Australia, but are more limited in variety. The colony, from its dryness, lacks a number known elsewhere. Enormous areas are almost destitute of forests or of timber trees. The *Eucalyptus* family, so valuable for timber and gum as well as for sanitary reasons, are fairly represented. Acacias are abundant, the bark of some being an article of commerce. Flinders range has much of the valuable sugar gum, *Eucalyptus Corymbocarpa*, which is being now preserved in forest reserves. Its timber is very hard and strong, not warping, resisting damp and ants. The head flowered stringybark, *Euc. capitellata*, has a persistent bark. A sort of stringybark, *Euc. tetradonta*, is found in Northern Territory. The gonty stem tree (*Adansonia*) or monkey bread of the north is a sort of baobab. About 500 northern plants are Indian. The *Tamarindus indica* occurs in Arnhem land, with native rice, rattans, and wild nutmeg. The cedar is of the Indian variety. Pines are numerous in the south, palms in the north, among the most beautiful is the *Kentia acuminata*. Banksias are very common in sandy districts. Flowering shrubs are common in the south. There are 130 known grasses in Northern Territory.

Fisheries—Whaling was formerly an important industry about Encounter Bay, as sealing was in Kangaroo Island. The whales have migrated, and the seals are exterminated. On the northern side trepan or *Uchlo de mer* fishery has commenced, and pearl fisheries have been established. Of fish within colonial waters there are forty two peculiar genera. The tropical north has similar fish to those of North Queensland, while those of southern bays resemble many of the species of Victoria, Tasmania, and New South Wales. There are the barracouta, bonito, bream, carp, catfish, rock cod and Murray cod, conger, crayfish, cuttle, dogfish, eel, flatfish, flat head, flounder, flying fish, gadfish, grayling, gurnard, hake, John Dory, ray, salmon (so called), schnapper, scorpion, shark, sole, squid, swordfish, whiting, &c. Though called by English names, the fish do not always correspond to those in Europe. The Murray cod is a noble freshwater fish.

Commerce—There is little speculative trade, the shipping being employed in the conveyance of the exports of the colony and the introduction of needful supplies. The imports during 1884 amounted to £5,740,353, of which £2,983,296 came from the United

* One genus of this remarkable family—the *Liposa*—is confined to the district.

kingdom, £997,785 from New South Wales, £714,272 from Victoria, £33,460 from Tasmania, £34,675 from New Zealand, £97,230 from India, £28,011 from Natal, £55,598 from Hongkong, £19,201 from Canada, £239,093 from Mauritius, £54,945 from China, £19,023 from France, £61,727 from Germany, £72,214 from Norway and Sweden, £186,236 from the United States. Of the exports, £6,623,704, there went to the United Kingdom £4,051,864, New South Wales, £773,240, Victoria, £651,019, Queensland, £277,746, Cape Colony, £249,844, India, £144,287, Western Australia, £132,554, Natal, £78,118, France, £57,500, Mauritius, £52,010, Belgium, £33,092. Among the exports during 1884 were wool, £2,616,626, wheat, £1,694,005, flour, £794,812, copper, £469,231, sheepskins, £87,455, silver lead, £66,592, bark, £45,049, jams, £35,338, horses, £30,845, tallow, £28,403, wine, £17,061, gold, £15,469. There were imported overland 411,307 sheep, and exported 168,770. Of shipping, there entered 1120 vessels of 909,335 tons, and cleared 1111 of 925,197. The British amounts were 768,301 and 783,121 tons respectively. In the Northern Territory the imports were £140,229, exports £90,411, the gold export for the last six months of 1885 was £33,869. The assets of the eleven banks at the close of 1885 were £13,380,716,—total deposits £5,880,950. The Government savings bank, on June 30, 1885, had 53,164 depositors, with £1,571,233 as balances—five per cent. interest being allowed.

Manufactures—Increased attention has been lately directed to local industries, and a more protective tariff has been enforced with a view to their development. The official returns for March 31, 1886, gave 640 works employing 7952 men and 1350 women.

Communication—The district councils have charge of many of the roads. The general dryness of the country is favourable to the condition of roads. Railways have been constructed for the conveyance of farming produce to market, the carriage of minerals to port, and the tapping of the Murray river traffic from the east. At the beginning of 1886 there were 1211 miles of railway open, and 570 in course of construction. The working expenses during 1885 came to £386,000, and the revenue to £566,000. There are several tramways, supplementing railway traffic.

Water Supply—The Government is aiding the railway movement for opening out the interior by the construction of waterworks and public reservoirs. To supply Adelaide, independently of the Torrens river, there has been an expenditure of £866,942. Kapunda has a reservoir of 41,200,000 gallons, Port Pirie of 25,700,000, Mount Barker of 6,000,000, Port Augusta of 666,000, Mount Gambier and Gawler each of 279,000. There are large storage tanks at many places, e.g., for 810,000 gallons at Moonta.

Administration—The governor is the representative of the crown. The legislative council, of twenty-four members, one-third retiring every three years, is chosen by 32,000 electors. The house of assembly, of fifty-two members, is appointed for three years by 60,000 electors. Responsible government dates from 1856. The public debt, contracted for useful public works, was £18,000,000 in 1886. For the year 1884–85 the revenue was £2,157,931, but expenditure was £2,430,513. A revision of the tariff was necessary. Customs yielded £511,230, railways, £662,455, against working expenses £411,850, land sales, £333,369, land rents, £132,013, waterworks, £72,366. The expenditure included £311,189 for public works, besides loans, police, £102,784, civil establishments, £73,628, legal, £50,051, charitable institutions, £36,968 (there being no poor law), military defences, £30,473, immigration, £31,129, &c. The Northern Territory gave £71,518 as receipts to the state, but with £85,000 charges. The revenue for 1885–86 was £2,279,039, and the expenditure £2,383,290. No Australasian colony has done so much for the good of the aborigines and the advance of good morals as South Australia. The administration is just and firm, being well sustained by public sentiment.

Education—Not being so wealthy as its eastern neighbours, the colony has not been able to devote so large an amount to schools, still, a grant of £126,000 was made during 1884–85 towards the instruction of 50,000 pupils. Of 450 schools, half are called public, half provisional for thinly peopled districts. Payment from scholars is not dispensed with as in Victoria. Lands are being set apart as educational grants for the future. All religious denominations are equal in the sight of the law, none receiving any state aid. Bible reading is sanctioned before school hours, and any religious lessons may be given at the close of school time. The Adelaide university, so richly endowed by the colonists, receives an annual grant of £2550 from the local parliament.

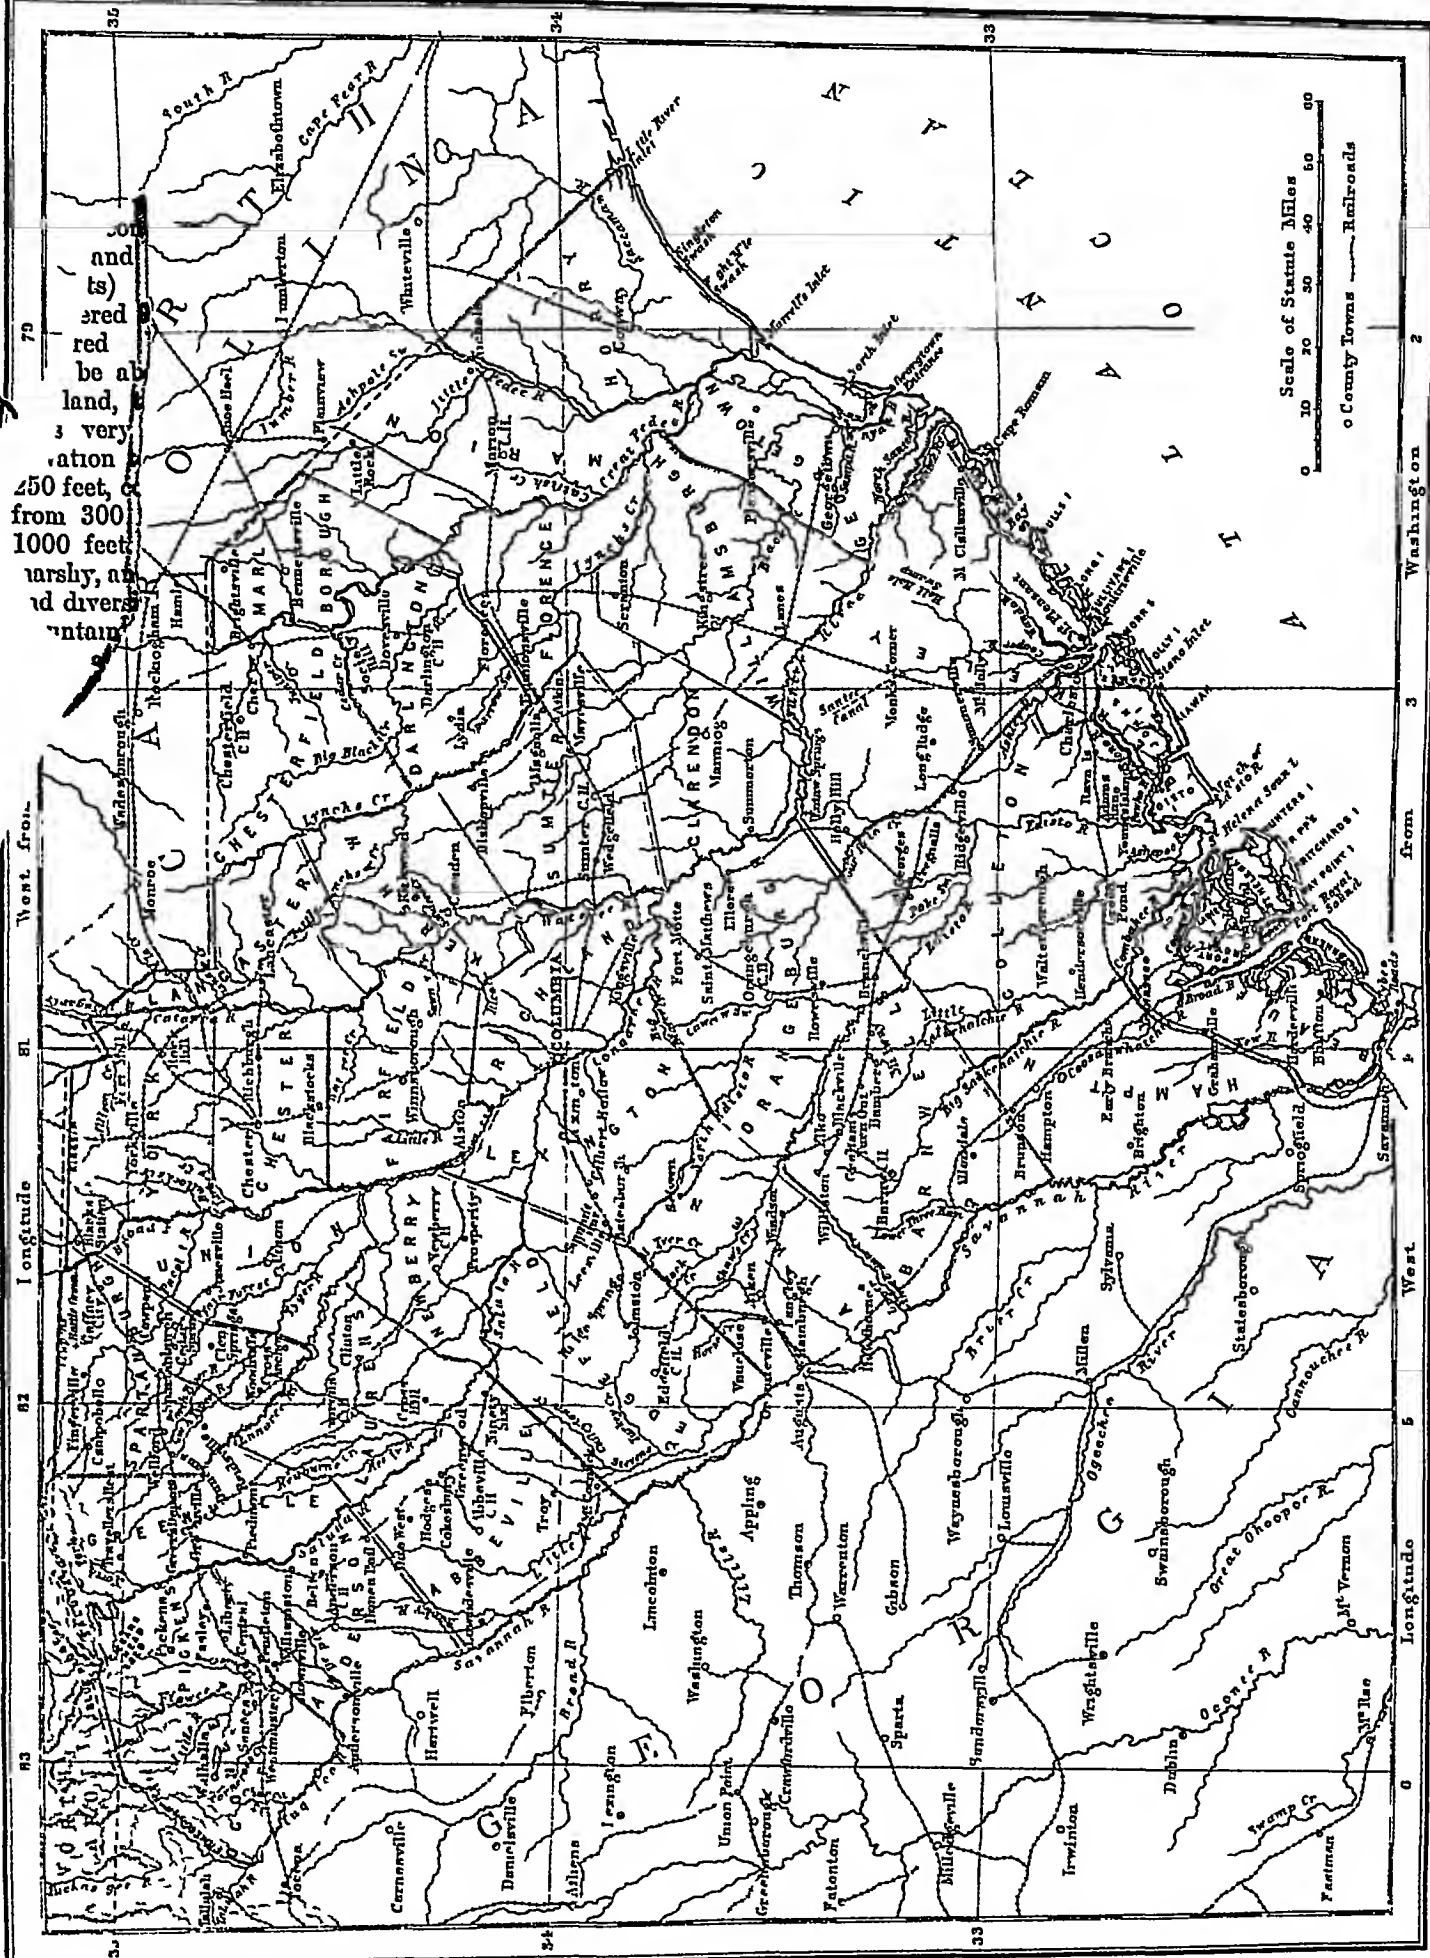

Population—Including the Northern Territory, the population was returned in 1881 as 279,865 (149,530 males, 130,335 females), in addition to 63 to aborigines (3478 males, 2868 females). The births during 1885 were 12,046, and the deaths 3987 (2205 males and 1782 females). Classified at the last census according to religion, the population may be thus stated—Church of England, 76,000, Roman Catholic, 42,920, Wesleyans, 42,103, Lutherans, 18,617, Presbyterians, 17,917, Baptists, 14,000, Bible Christians, 10,500, Primitive Methodists, 10,350, Congregationalists, 9908. The population in the Northern Territory, 3500, contains only about

a hundred females, but has 3000 Chinamen. More than half the people of South Australia, whether of English or German parentage, are native born. In 1886 the population was 325,000.

History—Though the coast of Northern Territory was well known to Portuguese and Spanish navigators as early as perhaps 1530, being called Great Java, it was not surveyed till 1644, when Tasman laid down the line of shore pretty accurately. The western part of the southern coast had been seen and named Nuyt's Land in 1627. But Flinders, by his discovery of the two great gulfs, Kangaroo Island, and Encounter Bay, in 1802, was the first to reveal South Australia proper. Captain Sturt descended the Murray in 1830, and looked over the hills near Adelaide. The first to direct attention to a settlement there was Major Barrow, who communicated with the colonial office in February 1831. His suggestion was to establish, at no charge to the British Government, a private company, that should settle a party on Yorke Peninsula. He believed a large river entered Spencer Gulf. In August Colonel Torrens and others proposed to purchase land between 132° and 141°—500,000 acres at 5s. an acre. Some were in favour of Spencer Gulf, others of Kangaroo Island, and a few for the mainland towards the Murray. Memorialists in 1832 sought a charter for the South Australian Association, giving extensive powers of self government. Land sales were to pay the passages of free labour, chiefly young married people, and no convicts were ever to be sent thither. Lord Goderich did not favour the scheme, and thought a colony with free institutions might prejudice the interests of New South Wales, while free trade would interfere with the English navigation laws. After much negotiation, the English authorities regarded the scheme more favourably, but would not consent to give the company the powers they sought. The company receded in their demands, and offered security for the proper observance of law and order, while depositing cash for the purchase of land. Captain Sturt in 1834 informed the colonial secretary that Spencer Gulf and Kangaroo Island were objectionable, but that the eastern side of St Vincent Gulf was the best locality. In 1835 the ministry got an Act passed for the erection of a colony, under commissioners appointed by the crown, who would be responsible for their acts to the British Government. It was arranged that a local government should be established when the settlement had 50,000 people. Mr George Fife Angas advanced a large sum as security to the state. Though the first settlers were sent to Kangaroo Island, all were afterwards gathered on the Adelaide plains. The colony was proclaimed under a gum tree, December 28, 1836. Great delay took place in the survey of land. The South Australian Company purchased large tracts from the commissioners at 12s. per acre and sold at 20s. A general speculative spirit arrested progress. Governor Gawler went into extravagant outlay on public buildings, &c., and drew against orders upon the English treasury. Such difficulties arose that the British rulers had to suspend the charter in 1841 and make South Australia a crown colony. A revival of prosperity took place when the farms were tilled and poverty had taught prudence. Copper and lead mines were subsequently discovered. Kapunda in 1843, and the Burra Burra copper mine in 1845, greatly aided in the restoration of commercial credit. The gold fever in Victoria drew off numbers in 1852, but the good prices then realized for breadstuffs gave a great impetus to farming. It deserves to be mentioned that rarely if ever has a colony been so favoured as South Australia in the character of its early settlers. (J. B. O.)

SOUTH BEND, a city of the United States, the county seat of St Joseph county, Indiana, received its name from its position at a great bend of the St Joseph river, which is navigable to this point from its mouth at St Joseph on Lake Michigan. By railway the city is 85 miles east of Chicago. It is a great manufacturing centre, with iron-works, carriage, waggon, plough, and sewing machine factories, flour mills, paper-mills, &c. The court-house is one of the best buildings in the State, and the Roman Catholic university of Notre Dame, St Mary's academy, and St Joseph's academy are institutions of some importance. The population of the city numbered 1652 in 1850, 7206 in 1870, and 13,280 in 1880.

SOUTH CAROLINA, one of the original thirteen *Plato V.* States of the American Union, commonly known as the Palmetto State, from the abundance of this kind of palm on the coast, once formed a part of that vast territory of the New World claimed by the Spaniards under the name of Florida and by the French under that of New France, or, to be more concise, it comprised the southern or lower portion of what was formerly styled Carolina, and subsequently divided into North and South Carolina. It lies

between 32° 4' 30" and 35° 12' N lat and between 78° 25' and 83° 49' W long. In shape it is an irregular triangle, the vertex resting upon the Blue Ridge Mountains in the extreme north-west, while the Atlantic forms its base. It is bounded N and NE by North Carolina, SE by the Atlantic, and SW by the Savannah river, which, with its tributaries the Tugaloo and Chatauga, separates it from Georgia. The state is 189 miles long and 160 broad, containing 30,961 square miles or 19,815,040 acres, and is divided into thirty-four counties (formerly districts). At the census of 1880 the population numbered 995,577, of whom 391,105 were white, the rest

surface. coloured. Very few Indians are to be found. The surface may be about equally divided into high, middling, and low land, the last-named rising from the sea coast, where it is very flat and level, and gradually increasing in elevation towards the interior, where it attains a mean of 250 feet, continuing to the north line, where, after varying from 300 to 800 feet it reaches its highest elevation of 1000 feet. The land along and near the coast is low, marshy, and swampy, especially on the rivers' banks, rolling and diversified towards the centre, and undulating near the mountain slope, but in places abrupt, King's Mountain rising almost perpendicularly 500 feet. The chief elevations in this section are the Saluda Mountains, spurs of the Blue Ridge, King's Mountain (1692 feet), Paris Mountain (2054 feet), Table Rock (3000 feet), Caesar's Head (3118 feet), and Mount Pinnacle (3436 feet). This region abounds in beautiful and picturesque scenery, rendering it attractive to tourists, and making it a great summer resort.

vers. The land is irrigated and well-drained by numerous rivers, the largest of which is the Santee, formed by the Saluda, Congaree, Catawba, and Wateree, uniting at the centre of the State. The other rivers of any size are the Waccamaw, Lynnh's, Great and Little Peedee, forming the Peedee, Black, Wando, Ashley, Cooper, Edisto, Combahee, Ashepoo, Coosaw, Port Royal, and Broad (on the coast), this last being more of a bay. The sea-coast is fringed by numerous islands, and indented by bays and inlets,—Winyaw and Bull's Bays, Charleston Harbour, Stono Inlet, North and South Edisto Inlets, St Helena Sound, and Port Royal,—the last one of the finest harbours in the world, as its name, said to have been given on this account by the early discoverers and explorers, would imply. The entire coast south of Winyaw is composed of a network of creeks and sounds, so that, for small craft, navigation inland may be had from this point to the mouth of the Savannah on the extreme south-west. Most of the rivers rising in the mountains are navigable nearly to the foot-slope. Here numerous rapids and waterfalls afford excellent mill-power. Canals throughout the State are not numerous, the few formerly in use having been abandoned in favour of the railroads. The Santee Canal, connecting that river with the headwaters of the Cooper, 22 miles in length, has given place to the North Eastern Railway.

climate. The climate of South Carolina is mild and genial, snow falling in the mountains but rarely in the middle sections, and seldom or never along the coast. The sea islands generally, as well as the pine barrens, are healthy, furnishing the planter with a summer home and safe retreat from the malaria of the rice lands. These regions were formerly innocuous to the whites, as they still are to the negroes, but subsequent clearance and cultivation have rendered them fatal in summer. The midlands are considered healthy in all parts except here and there along the creeks, while the mountain region is unexceptionable.

earth- quakes. The coast of South Carolina, like places in the same latitude, is subject to violent storms, tornadoes, and cyclones, which make their annual visits on or about the autumnal equinox, doing much damage. Till quite recently the district has never been seriously troubled with earthquakes. Slight tremors have indeed been felt

and recorded since 1754, without, however, causing serious injury. But on the night of the 31st August 1886 Charleston was visited by an earthquake which was followed by other shocks and tremors, which continued night and day at intervals with greater or less violence, as the following list shows —

August 27	1 shock, slight.	Sept. 8	1 shock, slight.
August 28	1 shock, slight	Sept. 10	1 shock, slight.
August 31	5 shocks, destructive	Sept. 12	1 shock, slight.
Sept. 1	3 shocks, severe	Sept. 15	2 shocks, moderate
Sept. 2	3 shocks, severe	Sept. 21	1 shock, severe.
Sept. 3	2 shocks, severe	Sept. 22	1 shock, moderate, local
Sept. 4	2 shocks, slight.	Sept. 27	1 shock, severe
Sept. 5	1 shock, moderate	Sept. 28	1 shock, moderate
Sept. 7	2 shocks, slight	Sept. 30	1 shock, slight.

The main shock was very destructive to property, while about forty lives were lost, and many more were injured. Cracks several yards in length and varying from one to four inches in width appeared, and in some places in the suburbs of the city fissures of much larger proportions threw up water to the height of several feet. There was no warning given except that in the small town of Summerville, about 23 miles to the north, considerable disturbance was caused by thuds and tremors with detonations on the 27th and 28th, felt on the latter date to some extent in Charleston. The violence of these shocks was confined almost exclusively to this State, though they were felt in a slighter degree in Georgia and North Carolina.

The soil in the low country is remarkably fertile, the river swamps and reclaimed marshes being admirably adapted to the cultivation of rice, while the sandy loam of the sea islands and surrounding main produces the finest long staple, black seed, or sea island cotton of silky fibre. As we recede from the salt the staple becomes shorter and the plant has a less luxuriant growth. The rice produced here, noted abroad as Carolina rice, is considered first in the markets of the world. The State was the first to introduce rice culture in America, the seed having been brought in 1693 by a vessel from Madagascar. Abundant crops are raised of wheat, rye, maize, oats, barley, buckwheat, pease, beans, sugar, tobacco, indigo, sorghum, broom corn, sunflower, guinea corn, sweet and Irish potatoes, hemp, flax, and hops. Numerous orchards, all over the State, furnish quantities of apples, pears, quinces, plums, peaches, nectarines, apricots, cherries, and along the coast figs, oranges, lemons, olives, and pomegranates. The raspberry, blackberry, mulberry, and whortleberry are produced. The strawberry is extensively cultivated along the coast, and shipped in immense quantities to the northern markets. Of nuts, the walnut, pecan, chestnut, hickory, shell bark, hazel nut, and chinquapin may be mentioned. The grape grows wild in many portions of the State, and in great varieties, which, when cultivated, yield a delicious wine. In certain sections hundreds of acres are devoted to the culture. The gardens and farms produce in abundance turnips, beets, parsnips, carrots, artichokes, mustard, benne, rhubarb, arrowroot, water and musk melons, cucumbers, cabbages, kale, lettuce, cayenne pepper, squashes, okra, pumpkins, onions, leeks, beans, radishes, celery, green pease, and tomatoes,—the last two from early spring to mid winter. The jasmine, Cherokee rose or nondescript, wild honeysuckle, and sweet brier perfume the woods, the dog wood and fringe tree abound in the forest, and garden flowers in the cities, especially Charleston, Columbia, and Beaufort, are the admiration of strangers. Conspicuous among these are the *Camellia japonica* of all varieties and shades, azalea in every hue, roses of numberless descriptions, hyacinth, snowdrop, violet, dahlia, tulip, verbena, sweet olive, and heliotrope. Valuable and almost inexhaustible forests extend over the greater part of the State, the long leaf or yellow pine, confined chiefly to the low country, covering 10,000,000 acres, and furnishing immense quantities of timber, tar, pitch, turpentine, and rosin. Here and elsewhere are found the magnolia, sweet and black gum, white, water, red, and live oak, black walnut, elm, hickory, maple, sycamore, ash, cypress, chestnut, beech, locust, persimmon, dogwood, poplar. The palmetto is peculiar to the coast.

The forests abound in deer, wild turkeys, foxes, wild cats, raccoons, opossums, rabbits, and squirrels, and along the water courses are found the musk otter, &c. Among the birds are pigeons, doves, partridges, woodcock, snipe, immense flocks of wild ducks, including the English or canvas back, teal, blackhead, &c. Freshwater fish of every variety are taken in all the streams in the interior, and the bays and inlets furnish whiting, mackerel, bass, flounder, sheepshead, shad, mullet, blackfish, sturgeon, terrapin, turtle, shrimps, crabs, and oysters. Quantities of salmon and carp have been furnished by the fish commissioners for stocking the waters.

Minerals are liberally diffused over the State. Gold is found in Lancaster, York, Union, Spartanburg, Greenville, Pickens, and Abbeville counties, copper in York, Spartanburg, and Pickens, lead in the last, iron of a superior quality in Union, Spartanburg, Greenville, and Pickens, manganese in Lancaster, York, Chester,

Union, Spartanburg, Greenville, Pickens, Anderson, Abbeville, and Edgefield, limestone in Chesterfield and Lancaster, plumbago in Spartanburg, soapstone in Fairfield, Chester, York, Spartanburg, Laurens, Greenville, Pickens, Abbeville, and Edgefield, coal in Chesterfield and Marlboro. Limestone abounds in nearly all the upper counties, but chiefly in Laurens and Spartanburg. The finest blue and grey granite is found in the middle and upper sections, sandstone, burrstone, and flagstone in Edgefield, Pickens, York, and Fairfield. Pottery and porcelain clay, quartz, and sand for glass exist in many places. Tuomey states that "the aluminous formations that occur in immense beds of the finest porcelain clay are often exposed by the denuding effects of water and lie in rich strata upon the very surface, ready to the hand of the manufacturer. Between Aiken and Graniteville the beds are in many cases 60 feet thick, while those in the Savannah river near Hamburg are from 10 to 15 feet and of unsurpassed purity." The Aiken council committee report in this vicinity immense beds of different kinds of clay, from the purest and whitest kaolin to the dark colored mud of which bricks are made, sands of all hues, some as fine as flour, others with large coarse crystals, siliceous earths of many kinds, ferruginous sandstones, conglomerate shell, burrstone, mica, feldspar, and ochres of different colours. But a short distance off a deposit of magnesia is found, and potash can readily be made in the surrounding forests. Experts have pronounced the sands to be admirably adapted for making glass and crystal, and the quality of the kaolin is admitted to be equal, if not superior, to that of which Staffordshire ware is made. It is doubtful if the combination of the ingredients of glass and earthenware can be found in such immediate proximity anywhere else. Mineral springs exist in several of the upper counties.

lways. Railroads are on the increase. The South Carolina Railway, between Charleston and Augusta, Ga., was, at the time of its completion, the longest continuous railroad in the world.

tries. Manufactures are growing in importance, chief among them are cotton yarn and cloth, flour, lumber, turpentine, and fertilizers. The capacity of twenty nine mills now in operation is estimated at 14,821,166 lb of yarn, 79,442,327 yards of cloth, and the value of product \$9,097,464. In 1880 there were 82,824 spindles and 1676 looms, in 1884 195,112 spindles and 3652 looms. The number of lumber mills at work is 729, employing 5894 hands and a capital of \$2,920,870. The value of their annual production is \$5,592,565. Of turpentine stills there are 291, with 6991 hands and a capital of \$1,454,800, with an annual production to the value of \$2,912,271. These figures show an increase of 100 per cent in less than four years. The fertilizers are valued at \$3,346,400, and the miscellaneous manufactures at \$2,114,680. The whole value of manufactured products was in 1860 \$8,615,195, in 1870, \$9,858,981, in 1880, \$16,738,008, in 1884, \$32,324,404. South Carolina phosphates are of recent date, but their importance may be shown by stating that they pay yearly, by direct taxation, an amount for royalty which is 20 per cent. of the whole income of the State. The value of this rock was first pointed out by Mr Jonathan Lucas, a planter, who afterwards materially assisted in developing its usefulness. The first company, the Charleston South Carolina Mining and Manufacturing Company, was formed in 1867. There are now fourteen land and eleven river mining companies with capital ranging from \$10,000 to \$200,000. In addition to these there are a number of individuals who are licensed by the State to mine in the navigable streams, employing an estimated capital of about \$50,000. The total amount of phosphate rock mined and shipped in 1868-70 was 20,000 tons, in 1871, 50,000 tons, in 1875, 115,000 tons, in 1880, 190,000 tons, and in 1883, 355,000 tons,—the total since 1868 being 2,290,000 tons. Of this amount 1,078,070 tons were river and 1,211,930 land rock. The capital invested in the former is \$525,000, and 649 hands are employed (wages \$259,300), with an annual production of \$307,170, in the latter the corresponding figures are—capital \$1,930,000, hands 1286, wages \$363,560, production \$1,283,830.

The six gold mining counties report eleven mines in operation, employing 600 hands, with a capital of \$440,000 and an annual production of \$90,000. The same counties report eighteen gold mines or gold bearing areas not now worked, one of the mines has a capital of \$10,000. Ten counties report quarries or kaolin beds worked and unworked, there are twenty five granite quarries, five kaolin beds, and one soapstone quarry. There are also in the State large unworked deposits of mica, pyrites, corundum, and marl, with some silver. The quarries and kaolin works, with a capital of \$36,350, have an annual production of \$220,000.

The upland cotton crop of 1883 was 468,227 bales of 400 lb. The corn area was 1,359,593 acres, and the production 10,876,744 bushels. 321,958 acres in oats yielded a crop of 4,187,082 bushels. Of wheat (182,215 acres) the yield was 1,388,731 bushels. The rice crop of 1883-84 was 33,600 tierces. The sea island cotton crop was 9500 bags. This last, as well as the small grain and subsidiary crops, has suffered a decline in the last few years of 25 to 35 per cent.

The proportions of white and coloured labour in the State are about 30 per cent. and 70 per cent. respectively. The rate of wages

paid is from \$8 to \$9 a month for men and \$6 for women, with board. About 23 per cent. of white women and children work on the farms, and about 61 per cent. of the coloured. The systems used are—the contract, in which services rendered are paid by giving the labourer the use of the land and house, or where the wages are paid monthly, or a portion monthly and the remainder at the end of the year, and the tenant system, in which the labourer rents the land, and from the crop pays the landlord the rent and for the use of the animals. Land varies in price from 50 cents for pine barren to \$100 for choice farming land.

Horses and mules are raised at very little cost. Ordinary scrub live cattle are seldom housed, roaming the forests at will, except when stock, herded for branding or for driving to market. Sheep thrive away from the salt, and are profitable in the mountains. Hogs, not improved breeds, like cattle, have the liberty of the woods, and are taken with dogs when needed. According to estimates of improved stock, there are 792 Jerseys, 177 Ayrshires, 50 Devons, 33 Holsteins, 1 Guernsey, besides a number of Shorthorns and Brahmins. Merino, South Down, Oxford Down, and Broad Tail sheep are raised in many parts of the State, with Essex and Berkshire hogs.

Free schools trace their origin as far back as 1710. A system of free schools was inaugurated in 1811. The present public school system was established in 1868. It provides free instruction to pupils of both races, in primary and intermediate grades. Their management is under the direction of the State board of examiners, consisting of the State superintendent of education, and four other persons appointed by the governor. In each county the school commissioner is elected by the people for two years. The schools are supported entirely by taxation. There are 3562 public schools in the State. The number of persons in the State between the ages of six and sixteen is 281,664, of whom 51,440 are white males, 49,749 white females, 90,897 coloured males, 89,578 coloured females. The number of pupils enrolled is 178,023 (41,819 white males, 36,639 females, 48,418 coloured males, 51,147 females). The number of male white teachers employed is 1137, females 1205, coloured males 982, females 449,—making a total of 3773. There are 3562 public schoolhouses, valued at \$405,097.31. Institutions for higher education, supported by the State, are the South Carolina College and South Carolina Military Academy for white males, and the Claflin College for coloured persons of both sexes. There is an institution for the education of the deaf, dumb, and blind. There are, besides, numerous private schools and colleges.

Churches of all denominations multiplied in the State during the colonial period, and subsequently Episcopalians, Presbyterians, Independents, Baptists, and French Protestants established congregations in Charleston just after 1680. Methodists and Romanists came a century later, Jews in 1756, German Lutherans in 1759. The coloured people are for the most part Methodists, some being Baptists and Presbyterians, a few Episcopalians.

CHARLESTON (q v) is the largest city of the State. COLUMBIA Cities. (q v), the capital, has (1886) a population of 20,000, while that of Charleston is 60,000. Greenville, in the north west portion of the State, is a growing railway centre and manufacturing city, with a population of 10,000. Georgetown and Beaufort on the coast do a good shipping business in lumber and other exports. Spartanburg and Aiken are important places, the former as a railway centre, the latter as a health resort for invalid strangers in winter, when the population is more than doubled. Other towns are Newberry, Orangeburg, Florence, Camden, Sumter, Graniteville, Chester, Anderson, Abbeville, Winnsboro, Yorkville, Union, Cheraw, Walhalla, Piedmont, Port Royal, Marion, Darlington, Lancaster.

The executive department consists of a governor, lieutenant-governor, who is *ex officio* president of the senate, comptroller-general, treasurer, secretary of state, attorney general, and a superintendent of education, these are elected by the people, to serve two years. The legislative department embraces a senate and a house of representatives, which together are called the general assembly. The former is composed of thirty seven members, elected for four years, one from each county, except Charleston, which sends two. The house of representatives consists of 124 members, elected for two years. The judicial department consists of a supreme court and of circuit, probate, and justices' courts. The supreme and circuit court judges are elected by the general assembly,—the former for six years, the latter for four. The probate judges for each county are elected by the people, and the justices of the peace are appointed by the governor.

The first attempt to settle Carolina was in 1562, when Admiral History. Coligny obtained from Charles IX. of France permission to plant a colony of Protestants on the coast of Florida. An expedition was fitted out at the expense of the crown, and placed under the command of Jean Ribault. Fear of the Spaniards perhaps induced them to change their plans, and, entering Port Royal, they landed on Lemon Island, where they erected a pillar, and afterwards a fort, which they named, in honour of the king, *Arx Carolina*. Leaving a sufficient number to garrison the fort, Ribault returned to France. Two years later a second expedition under Laudonnière,

one of Ribault's men, was fitted out, but on landing at Port Royal it found no traces of the former. This colony likewise met with disaster, being massacred by the Spaniards from Florida. It was not until a century later that a permanent settlement was made by the English, who, after the Restoration, began to recognize their claim to a large territory in the southern district of North America. In 1662 a grant was obtained from Charles II, and in 1667 an expedition sailed under command of Capt William Sayle. They reached Port Royal, where they made a settlement, but a few years after removed to the west bank of the Ashley, and built a town which they called, after the English monarch, Charleston. Subsequently they again removed to Oyster Point, the present site of Charleston. (W SI)

SOUTHCOTT, JOANNA (1750–1814), was born in Devonshire about 1750, and was for a considerable time a domestic servant. She was originally an adherent of the Methodists, but, becoming persuaded she possessed supernatural gifts, she wrote and dictated prophecies in rhyme, and announced herself as the woman spoken of in the Apocalypse (ch. xii), affirming, when beyond the age of sixty, that she would be delivered of Shiloh on the 19th October 1814. For some days previous to this she was attended by her followers night and day, but Shiloh failed to appear, and it was given out that she was in a trance. She died of dropsy on the 29th of the same month. Her followers are said to have numbered over 100,000, and so late as 1860 they were not extinct.

Among her publications, which number over sixty, and are all equally incoherent in thought and grammar, may be mentioned *Strange Effects of Faith*, 1801–2, *Free Exposition of the Bible*, 1804, *The Book of Wonders*, 1813–14, and *Prophecies announcing the Birth of the Prince of Peace*, 1814. A lady named Essam left large sums of money for printing and publishing the *Sacred Writings of Joanna Southcott*. The will was disputed by a niece on the ground that the writings were blasphemous, but the Court of Chancery sustained it.

See Roberts, *Observations on the Divine Mission of Joanna Southcott*, 1807; Reece, *Correct Statement of the Circumstances attending the Death of Joanna Southcott*, 1815.

SOUTHEND, a watering-place of Essex, is situated on the north bank of the Thames, 5 miles west of Shoeburyness, and by the London, Tilbury, and Southend Railway, 42 miles east of London, with which it is also connected by steamer. It first sprang into notice from a visit of Queen Caroline in 1801, and, as it is the nearest watering-place to London, it is much frequented by excursionists, especially by the poorer classes. It is clean and well built, and at Cliff Town there are a number of large villas. Opposite Cliff Town there is a public garden called the Shrubbery. The bathing is good, but the tide recedes with great rapidity and for nearly a mile. The pier, which is 1½ miles in length, and on which there is a tramway, permits the approach of steamers at all tides. The public hall was erected in 1872 at a cost of £3000, and a mechanics' institution dates from 1881. The Rochford county court is held every alternate month in the public hall. A local board of health was established in 1866. The population of the urban sanitary district (area 3441 acres) in 1871 was 4561, and in 1881 it was 7979.

SOUTHERNE, THOMAS (1660–1746)—“Honest Tom Southerne,” to give the author of *The Fatal Marriage* the name by which his contemporaries usually called him—was a clever craftsman for the stage, according to the degenerate tradition of the Restoration dramatists,—with the eye of a born opportunist for the popular interests of the hour in so far as they could be turned to histrionic account, but without deeper seeing of the functions of the drama. Born in Dublin in 1660, he came to London and entered the Middle Temple in 1678, but only to desert later very speedily for dramatic authorship. His first play, *The Persian Prince, or the Loyal Brother*, is a good example, in its diplomatic reference to passing events and its veiled compliment to James, duke of York, of his ready tact as a playwright. The most important practical result of the play, which was remarkably successful on the stage, was

an ensign's commission, noteworthy in that it supplied Southerne with materials for later dramatization. After an interval of active service more plays followed, and were produced with equal success, of these *The Fatal Marriage* (1694), known also by the name of its heroine, Isabella, has the best claim to remembrance. Its strain of pathetic quality echoes the later Elizabethans in a way that contrasts suggestively with the shallow, if spirited, indecencies of Southerne's comedies, which, although their author was commended by Dryden for his purity as a playwright, are certainly not overweighed with delicacy. *St Anthony Love, or the Rambling Lady*, in which the hero assumes female disguise without accession of modesty, is a good example of the rest, one utterance of its hero, “Every day a new mistress and a new quarrel,” might indeed serve as a good motto of Restoration comedy in general. Except to the student, Southerne's work, however, is hardly of permanent interest. The Southerne of whom Pope, who ranked him as friend and praised him for his sterling qualities, remarked in some lines that

“Heaven sent down to raise

The price of prologues and of plays”

exemplifies what business tact and dramatic ingenuity can accomplish, for of real artistic faculty he had little. His plays resulted, through ingenious management, in a pecuniary return which dazzled Dryden and made their author a wealthy citizen, but they have not the quality of work which endures. He died in 1746.

SOUTHEY, CAROLINE (1786–1854), the second wife of Robert Southey, was born at Lymington, Hants, on December 6th, 1786. As a girl Caroline Ann Bowles showed a certain literary and artistic aptitude, the more remarkable perhaps from the loneliness of her early life and the morbidly delicate condition of her health,—an aptitude, however, of no real distinction. When money difficulties came upon her in middle age she determined to turn her talents to account in literature. Her first venture was the sending anonymously of a narrative poem called *Ellen Fitzarthur* to Southey, and this led to the acquaintanceship and lifelong friendship which in 1839 culminated in their marriage. *Ellen Fitzarthur* (1820) may be taken as typical, in its prosy simplicity, of the rest of its author's work, which reproduced the studied unadornment of certain portions of Southey's and Wordsworth's poetry without that glamour which, especially with the second of these writers, so often redeemed simplicity from mere baldness. Mrs Southey's poems were published in a collected edition in 1867. Her prose is on the whole more interesting than her verse, though—with rare exceptions—infected with like dulness. Among her prose writings may be mentioned *Chapters on Churchyards* (1829), her best work, *Tales of the Moors* (1828), and *Selwyn in Search of a Daughter* (1835). Her most interesting memorial is her correspondence with Southey, which, somewhat unfairly overlooked in the edition of the poet's *Life and Letters* edited by his son, has been published by Prof Dowden in the Dublin University Press Series. It was soon after her marriage that her husband's mental state became hopeless, and from this time till his death in 1843, and indeed till her own, her life was one of much suffering. Mrs Southey died at Buckland Cottage, Lymington, on July 20th 1854, two years after the queen had granted her an annual pension of £200.

Besides the works already mentioned, she wrote *The Widow's Tale, and other Poems*, 1822, *Solitary Hours* (prose and verse), 1826, *Tales of the Factories*, 1833, *The Birthday*, 1836, *Robin Hood*, written in conjunction with Southey, at whose death this metrical production was incomplete.

SOUTHEY, ROBERT (1774–1843), was born in Bristol on the 12th of August 1774. His father, a native of Somerset was an unsuccessful draper. To his mother,

Margaret Hill, Southey owed his buoyant spirits, his practical sense, and his earliest friends. The first of these, Miss Tyler, his mother's half-sister, took possession of him when he was three, under her care he saw and heard a great deal of theatres and of acting. His solitary life in an old maid's household threw him upon his own resources and developed a taste for reading. He was sent to several private schools, and had good fortune at none of them, in 1788 he went to Westminster, where he was scarcely more fortunate. After a brief sojourn he was expelled in 1792, because an essay of his on flogging, in a school magazine called *The Flagellant*, was resented by Dr Vincent, the head-master. At Westminster he gained the friendship of two boys who were faithful to him and helpful throughout his life, these were Charles Winn and Grosvenor Bedford. About this time his father died, his aunt, however, determined that he should go to Oxford. He was refused at Christ Church on account of the essay in *The Flagellant*, but Balliol gave him a home. At Oxford he led his own life, lived in his own thoughts, and got little or nothing from the university. In 1794 Coleridge dashed at Southey, took him by storm, and filled his head with plans for an ideal colony in the wilds. The new society, whose members were to have all things in common, was to be called "The Pantisocracy." Their life was to combine manual labour and domestic bliss, to attain the latter, Southey set his affections on a Miss Edith Fricker, whose sister married Coleridge. All this was intolerable to Miss Tyler, and Southey was banished. He and Coleridge then tried, by lecturing and journalism, to raise money for their American schemes, but luckily Southey's uncle, who had educated him,—Mr Hull, the English chaplain at Lisbon,—advised him to travel. On the 14th of November 1795, before he started, he was secretly married to Edith Fricker. On his return from Lisbon the marriage was acknowledged, and Southey wandered from one house to another in the south of England. He tried, or was urged to try, the three professions which are by courtesy styled "learned", it might be more true to call them the technical, the stereotyped professions. Southey was scared from all three,—from clericalism by dogma, from medicine by the dissecting-room, from law by its crabbed dulness. In literature alone he found his proper sphere, and in 1803 he settled down in his life-long home, Greta Hall, near Keswick. Henceforth his years were even and uneventful. He wrote and read with mechanical, with appalling regularity, his library grew to fourteen thousand volumes. He had children, and lost several, and his house was a refuge for the wife and family of Coleridge. With Wordsworth and Landor he formed close friendships. In 1813 he was made poet-laureate, and some years before his death he was offered a baronetcy—which, however, he with good reason declined. Two great sorrows embittered his life. In 1809 he lost his eldest boy Herbert, and in 1834 his wife was taken to a madhouse, whence she came back to die. In 1839 he married Caroline Bowles. That same year his memory failed, his speech became uncertain, and his power of writing soon went, softening of the brain had taken irremediable hold of the once tireless intellect. To the last he would hover round his books and handle them lovingly. He died on the 21st of March 1843, he is buried, near his first wife and her children, in Crosthwaite churchyard.

The amount of Southey's work in literature is enormous. His collected verse, with its explanatory notes, fills ten volumes, his prose occupies about forty. But his greatest works were left uncompleted, and this, in some sense, is typical of Southey's whole achievement in the world of letters, there is always something unsatisfying, disappointing, about him. He seldom realized or seldom found scope for his true bent in literature. This is most

true of his efforts in verse. In his childhood Southey fell in with Tasso, Tasso led him to Ariosto, and Ariosto to Spenser. These beautiful, these luxuriantly imaginative poets captivated the boy, and Southey mistook his youthful enthusiasm for an abiding, a life-long inspiration. His inspiration was not genuinely imaginative, he had too large an infusion of prosaic commonplace in his nature to be a true follower of Ariosto and Spenser. Southey, quite early in life, resolved to write a series of epics on the chief religions of the world. The subject was dangerous, and one epic is a life's work, it is not surprising that the too ambitious poet failed. His failure is twofold: he was wanting in artistic power and in poetic sympathy. With regard to the first, he says of himself, "It was long before I acquired this power,"—the power of plan and construction,—"not fairly, indeed, till I was about five or six and thirty." The fact is, he never acquired it, he never could construct a dramatic plot or mould it into artistic details. When his epics are not wildly impossible they are incurably dull, at the best their interest is extrinsic rather than intrinsic, pervaded by the glamour of historic romance rather than the light of pure poetry. And a man is not fit to write epics on the religions of the world when he can say of the prophet who has satisfied the gravest races of mankind,—Mohammed was "far more remarkable for audacious profligacy than for any intellectual endowments." Southey's age was bounded, and had little sympathy for anything beyond itself and its own narrow interests, it was violently Tory, narrowly Protestant, defiantly English. And in his verse Southey truthfully reflects the feeling of his age. This led him to say dreadful things about the Eastern religions in his prefaces to *Kekama* and *Thalaba*, it made *Joan of Arc* an incongruous blend of Rousseau, of Horace Walpole's romanticism, of the Surrey theatre, and of Lady Huntingdon, it gave Madoc, a Celt of the 12th century, the mind of a cold middle class Saxon evangelical of the regency. In the shorter pieces Southey's commonplace asserts itself, and if that does not meet us we find his bondage to his generation. This bondage is quite abject in *The Vision of Judgment*, Southey's heavenly personages are British Philistines from Old Sarum, magnified but not transformed, engaged in endless placid adoration of an infinite George III. When Southey sets himself to fondle the regent, he loses all sense of measure and propriety. In the *Funeral Ode* to the Princess he can assert of her father—

"Such the proud, the virtuous story,
Such the great, the endless glory
Of her father's splendid reign!"

This famous ode, "with the grace and beauty of which," Sir Henry Taylor thinks, "no facts could compete," is, it must be said, in many of its couplets, too like the average hymn. The twang of the hymn spoils two of Southey's best pieces. *The Holly Tree* ends—

"That in my age as cheerful I might be
As the green winter of the holly tree."

The last lines of *Stanzas Written in his Library*, a poem dear to the book lover, are painfully like a rhyme on a tomb stone—

"Yet leaving here a name I trust
That will not perish in the dust."

Some of his subjects, *The Poet's Pilgrimage*, for instance, he would have treated delightfully in prose, others, like the *Botany Bay Elogues*, *Songs to American Indians*, *The Pig*, *The Dancing Bear*, should never have been written. *The Retrospect*, of which this is a fair specimen,—

"There where my little hands were wont to rear
With pride the earliest salad of the year,"—

a living critic and biographer of Southey has compared to *The Descent of Villages*. Southey was not in the highest sense of the word a poet, but if we turn from his verse to his prose we are in a different world, there Southey is a master in his art, who works at ease with grace and skill. "Southey's prose is perfect," said Byron, and, if we do not stretch the "perfect," or take it to mean the supreme perfection of the very greatest masters of style, Byron was right. For good prose, plain, unassuming, natural, he is not surpassed in English. In his charming story of *The Three Bears* a phrase is often used which exactly describes his style, when the old lady finds what is neither too hot nor too cold, too large nor too small, she says it is "just right." Southey's prose is "just right,"—it expresses his meaning with simple and admirable precision. In his prose and in his criticism we of a later generation could do worse than learn from Southey, his sober writing is an excellent corrective for our prevailing faults. In prose the real Southey emerges from his conventionality. His interest and his curiosity are unbounded, as his *Common-Place Book* will prove, his stores of learning are at his readers' service, as in *The Doctor*, his patriotism is vigorous and healthy, as in the *Life of Nelson*, his criticism is sound, as in the *Lives of Cowper* and of Wesley. But the truest Southey is in his *Letters* the loyal, gallant, tender-hearted, faithful man that he was is revealed in them. Southey's fame will not rest, as he supposed, on his verse, all his faults are in that,—all his own weakness, and all the false taste of his age. But his prose assures him a high place in English literature, though not a place in the first rank even of prose writers.

SOUTHPORT, a municipal borough of Lancashire, England, and a favourite seaside resort, is situated between the estuaries of the Mersey and the Ribble, 18 miles north of Liverpool, and is a terminal station of three railway systems. Its foreshore consists of a great expanse of firm, bright sands, to the radiation of heat from which is attributed the mildness of its winter climate. Its proximity to Liverpool, Manchester, and other large manufacturing towns has drawn to it a large resident population, and its visitors, in quest of health and pleasure, number many thousands annually. Its spacious streets, laid out at right angles to each other, are bordered with trees and ornamental gardens. The promenade along the shore is two miles in length, in its centre is the pier, a mile long, down which tramcars are drawn by a stationary steam engine. Other facilities for outdoor enjoyment are provided in Hesketh Park (presented to the town by the late Rev. Charles Hesketh, rector of North Mools, and one of the lords of the manor), the Botanic Gardens, Kew Gardens, and the Winter Gardens. The last, laid out at a cost of £130,000, include a large conservatory, a fine enclosed promenade, a theatre, and an aquarium. There is also a glaciarium, or skating and curling hall, in which these amusements may be practised on real ice all the year round. The Victoria baths were erected in 1870 at an expenditure of £50,000. The principal public buildings are the town hall, the Cambridge hall (used for concerts &c.), and an extensive range of markets, erected in 1881 at a cost of £10,000. Among the benevolent institutions are a general infirmary, a convalescent hospital, a sanatorium for children, and a neuro-hydropathic hospital. Southport has also a free library and art gallery (the gift of the late William Atkinson), a literary and philosophical institute, and a college (Trinity Hall) for the education of the daughters of Wesleyan ministers, and the town council are now (1886) engaged in building a museum and schools of science and art. The first house in Southport (an inn for the reception of sea-bathers) was built in 1791, and soon after other houses were erected on the site now known as Lord Street. The population, which in 1809 was 100, had increased in 1851 to 4766, and in 1861 to 10,097. In 1867 the town received a charter of incorporation, and since then its progress has been remarkable. In 1871 the population of the borough (area 7526 acres) was 18,086, in 1881 this had grown to 32,206, and in 1886 it was estimated at 36,596. Its sanitary arrangements are very perfect, and the water supply is abundant and excellent. Southport gives its name to one of the parliamentary divisions of South-West Lancashire.

SOUTH SHIELDS. See **SHIELDS**, **SOUTH**.

SOUTHWARK. See **LONDON**.

SOUVESTRE, ÉMILE (1806–1854), a French novelist of merit, was born on April 15, 1806, and died on July 5, 1854. He was a native of Morlaix, and his affection for Brittany coloured most of his best work in after life. He had rather a chequered career of employment besides his literary pursuits. He was by turns a bookseller's assistant, a private schoolmaster, a journalist, and *professeur* at the grammar schools of Brest and Mulhouse. In 1848 he received what may sound to English ears the odd appointment of "professor of administrative style" in a school founded for the instruction of civil servants. His literary work, however, was his labour of love. He began like most Frenchmen with the drama, but was never very successful with it. In novel writing he did much better, and with Jules Sandeau (though on a somewhat lower level of writing, construction, and grasp of character) may be said to rank as the chief recent French novelist who deliberately aimed at making the novel an engine of moral instruction. With less genius and less sense of art than

Sandeau, he did not always escape the reproach of dulness. His best work is undoubtedly to be found in the charming *Derniers Bretons* (1835–1837) and *Foyer Breton* (1844) (where the folklore and natural features of his native province are worked up into story form, with a success hardly excelled by any other writer), and in *Un Philosophe sous les Toits*, which received the honour of an académie prize in the year 1851. This Souvestre deserved, not merely for his sentiments, but for his easy and agreeable style. He also wrote a not inconsiderable number of other works—novels, dramas, essays, and miscellanies.

SOWERBY, JAMES (1757–1822), was at first a painter, but soon applied his art to the illustration of botanical and conchological works, which are still highly valued, especially his *English Botany* (12 vols 8vo, 1846). His son George (1788–1854) followed in his father's steps, and produced a monumental work on conchology.

SOWERBY BRIDGE, a manufacturing town in the West Riding of Yorkshire, is situated on both sides of the river Calder, at the termination of the Rochdale Canal, and on the Lancashire and Yorkshire Railway, 2 miles south-west of Halifax, and 8 north-west of Huddersfield. Christ church, dating from 1526, was rebuilt in 1819. The other public buildings include the town-hall (1857) and the local board offices, opened in 1878, attached to which are the public baths and the slaughter-houses. The town is almost entirely the growth of the last fifty years. It possesses worsted and cotton mills, iron works, dye-works, and chemical works. The population of the urban sanitary district (area 536 acres) in 1871 was 7041, and in 1881 it was 8724.

SOZOMEN, church historian. Hermias Salamaneas (Salaminius) Sozomenus came of a wealthy family of Palestine, and it is exceedingly probable that he himself was born (not later than 400 A.D.) and brought up there, —in Gaza or the neighbourhood. What he has to tell us of the history of South Palestine was derived from oral tradition. His grandfather, as he himself tells us, lived at Bethel near Gaza, and became a Christian, probably under Constantius, through the influence of Hilarion, who among his other miracles had miraculously healed an acquaintance of the grandfather, one Alaphion. Both men with their families became zealous Christians and conspicuous for their virtues. The historian's grandfather became within his own circle a highly esteemed interpreter of Scripture, and held fast his profession even in the time of Julian. The descendants of the wealthy Alaphion founded churches and convents in the district, and were particularly active in promoting monasticism. Sozomen himself had conversed with one of these, a very old man. He was brought up under monkish influences, so he expressly states, and his history bears him out. As a man he retained the impressions of his youth, and his great work was to be also a monument of his reverence for the monks in general and for the disciples of Hilarion in particular. He became a lawyer and advocate in Constantinople, where as such he wrote his *Ἐκκλησιαστικὴ Ἱστορία* about the year 440. The nine books of which it is composed begin with Constantine and come down to the death of Honorius (423), but according to his own statement the author intended to continue it as far as the year 439. From Sozomen himself (iv 17), and statements of his excoptors Nicephorus and Theophanes, it can be made out that the work did actually come down to that year, and that consequently it has reached us only in a somewhat mutilated condition, at least half a book being wanting. A flattering and bombastic dedication to Theodosius II. is prefixed. When compared with the history of SOCRATES (qv), it is plainly seen to be a plagiarism from that work, and that on a large scale. Some three-fourths of the

materials, essentially in the same arrangement, have simply been appropriated from his predecessor without his being so much as named even once, the other sources to which Sozomen was indebted being, however, expressly cited. All that can be said to the credit of Sozomen is that he has been himself at the trouble to refer to the principal sources used by Socrates (Rufinus, Eusebius, Athanasius, Sabinus, the collections of epistles, Palladius), and has not unfrequently supplemented Socrates from them, and also that he has adduced some new authorities, in particular sources relating to Christianity in Persia, Arian history, monkish histories, the *Vita Martini* of Sulpicius, books of Hilarius, the whole of the ninth book is entirely drawn from Olympiodorus.

It is difficult to discern the motive for a work which was merely an enlarged edition of Socrates. But it is probable that Sozomen did not approve of Socrates's free attitude towards Greek science, and that he wished to present a picture in which the clergy should be still further glorified, and, above all, monasticism brought into still stronger prominence. In Sozomen everything is a shade more ecclesiastical—but only a shade—than in Socrates. Perhaps also he wrote for a different circle,—say, the monks in Palestine,—and could be sure that in it the work of his predecessor would not be known.

Sozomen is everywhere an inferior Socrates. What in Socrates still betrays some vestiges of historical sense, his moderation, his reserve in questions of dogma, his impartiality,—all this is wanting in Sozomen. In many cases he has repeated the exact words of Socrates, but with him they have passed almost into mere phrases. The inferiority of Sozomen to Socrates as an historian appears as much in the manner in which he transcribed him as in those passages where he introduces something new. The chronological scrupulosity of the earlier writer has made no impression on his follower, he has either wholly omitted or inaccurately repeated the chronological data. He writes more wordily and diffusely. In his characterizations of persons, borrowed from Socrates, he is more dull and colourless. After Socrates he has indeed repeated the caution not to be too rash in discerning the finger of God, but his way of looking at things is throughout mean and rustic. Two souls inhabit his book. One, the better, is borrowed from Socrates, another, the worse, is his own. Wherever he abandons his leader he frequently falls into mere retailing of stories, and prostrates himself in reverence before the poorest products of the religious fantasy of a degenerating age. Evidence of a boundless credulity with regard to all sorts of monkish fables is to be met with everywhere. Raisings of the dead are quite common occurrences with him, and he repeatedly gives accounts of enormous dragons. In the finding of the bones of saints he takes the highest interest, and even believes in the rediscovery of the tombs of the Old Testament prophets.

Where we still possess Socrates's account that of Sozomen very seldom has any consequence, but some of the additions he has made are instructive and important. The number of new acts of councils introduced by him is small. His monkish histories are as sources almost utterly valueless, his account of the Christians in Persia absolutely swarms with mistakes. It must, however, be noted that for the period from Theodosius I onward he has emancipated himself more fully from Socrates and has followed Olympiodorus in part, partly also oral tradition, here accordingly his statements possess greater value.

Editions and Literature.—Socrates and Sozomen have been edited by Stephanus (Paris 1641, Geneva 1612), Valesius (Paris, 1633-73), Reading (Cambridge, 1720), Huys (Oxford 1853, 1860). They are also to be found in vol. lxvii of *Migne's Patrologia* and there is an Oxford school edition (1844) after Reading. Bright edited Socrates according to the text of Hussey in 1878. There are *Testimonia Veterum in Valesius*; and *Notae* to a paper in *Tübinger Quartalschr.* (1839) p. 118 sq. (1861) p. 417 sq. contain emendations in Hussey's text and notes towards the history of the text and editions, see also Overbeck, in *Theol. Lit. Ztg.* (1870) No. 20.

Special studies have been made by Baronius, Miræus, Labbé, Valesius, Schroeckh, Lardner. See also Voss, *De Histor. Græcis*, Fabricius Harless, *Fontibus græcis Soc., Soc. ac Theod. in scribenda Historia Sacra uti unt*, (Göttingen 1823), S. 241 ff., *Gesch. u. Lit. d. K. G.* Hannover 1877, Duguet, *Époches* (1876), Harnack, "Socr. u. Soz.", in *Herzog-Plitt's Theol. Encycl.* (Münche, Pöde Neumann Pöndel), Dnmasius (Rade), *Arianism* (Gwatkins and discusses the manner in which Socrates was related to him) in *Rufinus after Julian* (Dr. Hroplie, Richter Clinton, the *Weltgeschichte* of Ranke the *Geich d. SPA, a watering-place of Belgium, in the province of Liège, 20 miles by rail from Liège via Pepinster, is beautifully situated, at a height of 814 feet above the sea, in the valley of the Wayai (a small sub-tributary of the Meuse). On the north and north east it is protected by the wooded range of hills known as the Spaloumont, or in its several parts as Bois de la Reid, Bois du Chiencul, &c., and on the south are a number of beautiful ravines cut in the Primary rocks of the district by small affluents of the Wayai. Much of the charm of the place is due to the promenades and drives along the sides and crests of the hills. The principal mineral spring called the Pouhon (a local word for "well") is enclosed in a pump-room in the centre of the Place Pierre le Grand. Public baths, fed by chalybeate streams collected in a remarkable reservoir at the hamlet of Nivesé, occupy a large building in Place Royale, erected in 1868, and in the same neighbourhood is the casino, with ball and concert rooms. An English church was built in 1872-76. A local industry is the production of fancy articles in lacquered wood (bois de Spa). A liqueur resembling Chartreuse is also manufactured under the name of "elixir de Spa." The population of the commune was 6930 in 1884. Several springs in the neighbouring district are nearly as celebrated as those of Spa proper, the Sauvenière waters, supposed to be effective against sterility, are half a mile distant.

Spa, said to derive its name from a Walloon word, *Espa*, for "fountain," was practically founded by a certain Wolf, or Collin le Loup, iron master of Breda, who had obtained benefit from the waters, and purchased the piece of ground containing the Pouhon spring from Erard de la March, bishop of Liège, in 1326. At the beginning of the 15th century the little town numbered 250 houses. The European celebrity of the waters dates from the 16th century, when they were drunk by the duke of Nevers, Margaret of Valois, Henry III. of France, and Alexander Farnese, and the fashion of visiting Spa became thoroughly established in the 18th century. The French Revolution, and, as far as English visitors were concerned, the attractions of the German watering places made known by Sir Francis Head, for a time turned the tide elsewhere, but since the middle of the century Spa has taken a new lease of prosperity.

SPAGNA, Lo (? -c 1529), the usual designation (due to his Spanish origin) of Giovanni di Pietro, one of the chief followers of Perugino. Nothing whatever is known of his early life, or of the circumstances under which he became a member of the Perugian school. A large number of panel pictures by him exist, of which some are painted with much grace and refinement of touch. There is, however, a very marked absence of individuality about his style, which seems like an imitation of the earliest manner of Raphael and that of Pinturicchio in a weaker and less virile form. The chief of his numerous panel paintings are the Nativity, in the Vatican, and the Adoration of the Magi, at Berlin. In 1510 Lo Spagna executed many frescos at Todi, and in 1512 several other mural paintings in and near Trevi. His most important works were frescos at Assisi and Spoleto, of which some exist in good preservation. He received the freedom of the city of Spoleto in 1516, as a reward for his work there. As is so often the case, Lo Spagna's frescos reach a much higher standard of merit than his panel pictures. The museum of the Capitol in Rome now possesses a very beautiful series of life sized fresco figures by him, representing Apollo and the Nine Muses. These are drawn with a strong feeling for grace of pose and beauty of expression, and are very remarkable for the delicate refinement of their colouring, in style they strongly recall Raphael's earliest manner. Lo Spagna was alive in 1528, but he appears to have died before 1530, as in that year a pupil of his named Doni completed a fresco in S. Jacopo, near Spoleto, which Lo Spagna had begun. SPAGNOLETTO. See RIBERA.

1

SPAIN

PART I.—GEOGRAPHY AND STATISTICS

SPAIN, a country rather more than twice the size of Great Britain including the adjacent small islands, constitutes in its mainland portion about eleven thirteenths of the Iberian Peninsula, and has in addition an insular area (in the Balearic and Canary Islands) of nearly 5000 square miles. On all sides except that of Portugal the boundaries are natural, the Peninsula being separated from Franco by the Pyrenees and on every other side being surrounded by the sea. On the side of Portugal a tract of inhospitable country led originally to the separation between the two kingdoms, inasmuch as it caused the reconquest of the comparatively populous maritime tracts from the Moors to be carried out independently of that of the eastern kingdoms, which were also well peopled. The absence of any such means of intercommunication as navigable rivers afford has favoured the continuance of this isolation. The precise line of this western frontier is formed for a considerable length by portions of the chief rivers or by small tributaries, and on the north (between Portugal and Galicia) it is determined to a large extent by small mountain ranges. The British rock of Gibraltar, in the extreme south of the peninsula, is separated from Spain by a low isthmus known as the Neutral Ground. The coast-line on the north and north-west is everywhere steep and cliffy. On the north there are numerous small indentations, many of which form more or less convenient harbours, but the current flowing along the coast from the west often leaves in the stiller water at their mouths obstructive bars. The best harbours are to be found on the *rías* or fiord like indentations in the west of Galicia, where high tides keep the inlets well scoured, here occur the fine natural harbours of Pontevedra and Vigo, Coruña and Ferrol, the last one of the chief stations of the Spanish fleet. Less varied in outline but more varied in character are the Spanish coasts on the south and east. Flat coasts prevail from the frontier of Portugal to the Straits of Gibraltar. Between the mouth of the Rio Tinto and that of the Guadalquivir they are sandy and lined by a series of sand dunes (the tract known as the Arenas Gordas). Next follows a marshy tract at the mouth of the Guadalquivir, after which the coast line becomes more varied, and includes the fine Bay of Cadiz. From the Straits of Gibraltar a bold and rocky coast is continued almost right round to Cape Palos, a little beyond the fine natural harbour of Cartagena. North of Cape Palos a line of flat coast, beginning with the narrow strip which cuts off the lagoon called the Mar Menor from the Mediterranean, bounds half of the province of Alicante, but in its northern half this province, becoming mountainous, runs out to the lofty headland of Cape Nao. The whole coast of the Bay of Valencia is low and ill-provided with harbours, and along the east of Catalonia stretches of steep and rocky coast alternate with others of an opposite character.

The surface of Spain is remarkable at once for its striking contrasts and its vast expanses of dreary uniformity. There are mountains rising with Alpine grandeur above the snow-line, but often sheltering rich and magnificent valleys at their base. Naked walls of white limestone tower above dark woods of cork, oak, and olive. In other parts, as in the Basque country, in Galicia, in the Serrania de Cuenca (between the head waters of the Tagus and those of the Júcar), in the Albarracín (between the head waters of the Tagus and those of the Guadalquivir), there are extensive tracts of undulating forest-clad hill country,

and almost contiguous to these there are apparently boundless plains, or tracts of level tableland, some almost uninhabitable, and some streaked with canals and richly cultivated—like the Requena of Valencia. While, again, continuous mountain ranges and broad plains and table lands give the prevailing character to the scenery, there are here and there, on the one hand, lofty isolated peaks, landmarks for a wide distance round, such as Monseñy, Monseñrat, and Mont Sant in Catalonia, the Peña Golosa in Valencia, Moncayo on the borders of Aragon and Old Castile, and, on the other hand, small secluded valleys, such as those of Vich and Olot among the Catalan Pyrenees.

The greater part of the interior of Spain is composed of a tableland bounded by the Cantabrian Mountains in the north and the Sierra Morena in the south, and divided into two by a series of mountain ranges stretching on the whole from east to west. The northern half of the tableland, made up of the provinces of Leon and Old Castile, has an average elevation estimated at about 2700 feet, while the southern half, made up of Estremadura and New Castile, is slightly lower—about 2600 feet. On all sides the tableland as a whole is remarkably isolated, and hence the passes on its boundary and the river valleys that lead up to it from the surrounding plains are geographical features of peculiar importance. The isolation on the side of Portugal, where the tableland gradually sinks to the sea in a succession of terraces, has already been referred to. On the north-west the valley of the Sil and a series of valleys further south, along both of which military roads have been carried from an early period, open up communication between Leon and the hill country of Galicia, which explains why this province was united to Leon even before the conquest of Portugal from the Moors. The passes across the Cantabrian Mountains in the north are tolerably numerous, and four of them are already crossed by railways. The two most remarkable are the Pass of Pájaros, across which winds the railway from Leon to Oviedo and the seaport of Gijón, and that of Reinosa leading down to the deep valley of the Besaya, and now crossed by the railway from Valladolid to Santander. In its eastern section the chain is crossed by the railways from Burgos to Bilbao and San Sebastian, the latter of which winds through the wild and romantic gorge of Pancorbo (in the north east of the province of Burgos) before it traverses the Cantabrian chain at Idiazabal.

On the north-east and east, where the edge of the tableland sweeps round in a wide curve, the surface sinks on the whole in broad terraces to the valley of the Ebro and the Bay of Valencia, and is crowned here and there by more or less isolated mountains, some of which have been already mentioned. On the north east by far the most important communication with the Ebro valley is formed by the valley of the Jalon, which has thus always formed a military route of the highest consequence, and which is now traversed by the railway from Madrid to Saragossa. Further south the mountains clustered on the east of the tableland (Albarracín, Serrania de Cuenca) render direct communication between Valencia and Madrid extremely difficult, and the principal communications with the east and south east are effected where the southern tableland of La Mancha merges in the hill country which connects the interior of Spain with the Sierra Nevada.

In the south the descent from the tableland to the

valley of the Guadalquivir is again comparatively gradual, but even here in the eastern half of the Sierra Morena the passes are few, the most important being the Puerto de Despeñaperros, where the Rio Magaña has cut for itself a deep gorge through which the railway now ascends from Andalusia to Madrid. Between Andalusia and Estremadura farther west the communication is freer, the Sierra Morena being there broken up into series of small chains.

Cantabrian
Mountains

Of the mountains belonging to the tableland the most continuous are those of the Cantabrian chain, which stretches for the most part from east to west, parallel to the Bay of Biscay, but ultimately bends round towards the south between Leon and Galicia. Almost everywhere it consists of two parallel ranges, the higher of which, the more southerly, is the immediate continuation of the Pyrenees. The highest summits of the chain belong to the Jura limestones of the Peñas de Europa, on the borders of the provinces of Santander, Oviedo, Leon, and Palencia. The highest of all is the Torre de Ceredo, which attains the height of at least 8750 feet, and next is the Peña Prieta (8300 feet). At the sources of the Sil the main chain divides into two branches, enclosing the fertile and thickly-populated district known as El Bierzo, once the bed of a lake, now watered by the stream just mentioned and its tributaries. The whole chain is remarkable for its intricate ramifications and its wild grandeur, but, as already indicated, is not so much of a barrier to communication as might be expected from its general aspect. Besides the railways above mentioned it is crossed at many points by bridle paths and roads.

Central
mountain
chains

A peculiar feature of the chain and the neighbouring parts of the tableland is formed by the *parameras* or isolated plateaus, surrounded by steep rocky mountains, sometimes even by walls of naked rock. Among the larger of these are the bleak districts of Sigüenza and Sorio, round the headwaters of the Duero,—districts which separate the mountains of the so-called Iberian system on the north-east of the tableland from the eastern portion of the central mountain chains of the peninsula. Of these chains, to which Spanish geographers give the name Carpetano-Vetónica, the most easterly is the Sierra de Guadarrama, the general trend of which is from south-west to north-east. It is the Montes Carpetani of the ancients, and a portion of it (due north of Madrid) still bears the name of Carpetanos. Composed almost entirely of granite, it has an aspect when seen from a distance highly characteristic of the mountains of the Iberian Peninsula in general, presenting the appearance of a saw-like ridge (*sierra*) broken up into numerous sections. Its mean height is about 5250 feet, and near its centre it has three summits (the highest named the Pico de Peñalara) rising to the height of nearly 8000 feet.

A region with a highly irregular surface, filled with hills and *parameras*, separates this sierra from the Sierra de Gredos farther west. This is the loftiest and grandest sierra in the whole series. Its culminating point, the Plaza de Almanzor, attains the height of 8725 feet, not far short of that of the highest Cantabrian summits. Its general trend is east and west, towards the south it sinks precipitously, and on the north it descends with a somewhat more gentle slope towards the longitudinal valleys of the Tormes and Alberche which separate it from another rugged mountain range, forming the southern boundary of the *paramera* of Avila. On the west another rough and hilly tract, similar to that which divides it from the Sierra de Guadarrama in the east, separates it from the Sierra de Gata, the westernmost and the lowest of the Spanish sierras belonging to the series. These hilly intervals between the more continuous sierras greatly facilitate the communica-

tion between the northern and southern halves of the Spanish tableland. The Guadarrama is indeed crossed by three good pass-roads, and even the Sierra de Gredos has a road across it connecting Avila with Talavera de la Reina by the Puerto del Pico, but for the most part there are only bridle paths across the sierras, and up to the present date not a single railway crosses any one of the sierras directly. The only railway crossing the central system of mountains is that from Madrid to Avila, which traverses the interval between the Sierras de Gredos and Guadarrama, passing through numerous tunnels on the way. A railway from Madrid to Segovia to cross the latter sierra at the Puerto de Navacerrada (5530 feet),¹ the pass at present crossed by the principal high road across these mountains, is now (1886) in course of construction.

On the southern half of the tableland a shorter series of sierras, consisting of the Montes de Toledo in the east (highest elevation 1600 feet) and the Sierra de Guadalupe in the west (highest elevation 5100 feet), separates the basins of the Tagus and Guadiana. The southern system of mountains bounding the Iberian tableland—the Sierra Morena—is even less of a continuous chain than the two systems last described. As already intimated, its least continuous portion is in the west. In the east and middle portion it is composed of a countless number of irregularly-disposed undulating mountains all nearly equal in height.

Even more important than the mountains bounding or crossing the tableland are those in the north-east and in the south, which are connected with the tableland only at their extremities. The former are the Pyrenees (q.v.), the latter are the Sierra Nevada, and the coast ranges till Sierra farther south. The Sierra Nevada, or "snowy sierra," is Nevada a well-defined chain, between 50 and 60 miles in length, and about 25 miles in breadth, situated to the south of the valley of the Guadalquivir, and stretching from the upper part of the valley of the Jemil in the west to the deep valley of the Almería in the east. It is composed chiefly of soft micaceous schists, sinking precipitously down on the north, but sloping more gently to the south and south-east. Its culminating summit, the Cerro de Mulhacen (11,660 feet), is the highest in Spain, and the range contains several other peaks upwards of 10,000 feet in height, and above the limit of perpetual snow. On both sides deep transverse valleys (*barrancas*) follow one another in close succession, in many cases with round basin-shaped heads, like the *cirques* of the Pyrenees. In many of these cirques repose alpine lakes, and in one of them, the Corral de Veleta, there is even a small glacier, the most southerly in Europe. On the south the transverse valleys of the Sierra Nevada open into the mountainous longitudinal valley of the Alpujarras, into which open also on the other side the transverse valleys from the most easterly of the coast sierras, the Sierra Contraviesa and the Sierra de Sierritas Almyara. The latter are continued farther west by the Sierra de Albama and Sierra de Abdalajiz. Immediately to the west of the latter sierra lies the gorge of the Guadalhorce, which now affords a passage for the railway from Malaga to Cordova, and beyond that gorge, to the west and south-west, the Serrania de Ronda, a mountain group difficult of access, stretches out its sierras in all directions. To Spanish geographers the coast ranges just mentioned are known collectively as the Sierra Penibética. North-east of the Sierra Nevada two small ranges, Alcaraz and La Sagra, rise with remarkable abruptness from the plateau of Murcia, where it merges in that of the interior.

The only two important lowland valleys of Spain are those of the Ebro and the Guadalquivir. The former valley occupies the angle in the north-east between the Pyrenees

¹ About 3700 feet above the level of Madrid, 2700 feet above that of Segovia.

and the central tableland, and is divided by ranges of heights proceeding on the one side from the Pyrenees, on the other from the base of the Moncayo, into two portions. The uppermost of these, a plateau of between 1000 and 1300 feet above sea-level, is only about one fourth of the size of the remaining portion, which is chiefly lowland, but is cut off from the coast by a highland tract connecting the interior tableland with spurs from the Pyrenees. The Guadalquivir basin is likewise divided by the configuration of the ground into a small upper portion of considerable elevation and a much larger lower portion mainly lowland, the latter composed from Seville downwards of a perfectly level and to a large extent unhealthy alluvium (*las marismas*). The division between these two sections is indicated by the change in the course of the main stream from a due westerly to a more south-westerly direction.

The main water-parting of the peninsula is everywhere near the edge of the tableland on the north, east, and south, and hence describes a semicircle with the convexity to the east. The Ebro alone of the great rivers flows into the Mediterranean. The following table gives the length of the principal Iberian rivers, with the area of their basins,—the length according to different authorities, the area of the basins according to Stralbitsky, whose measurements of area appear to be more trustworthy than those made by him of the length of rivers —

	Length in English Miles			Area in Square Miles
	Wagner	Ritter	Stralbitsky	
Ebro	442	416	470	38,580
Douro (Douro)	452	507	486	36,710
Tagus	565	553	566	31,865
Guadiana	510	490	316	25,300
Guadalquivir	337	350	374	21,580

With the exception of the Guadalquivir, none of the Iberian rivers is of great service for inland navigation, so far as they lie within the Spanish frontier. On the other hand, those of the east and south are of great value for irrigation, and the Júcar and Segura in the south east are employed in floating timber from the Serranía de Cuenca.

The Ebro and Tagus are described in separate articles (*q v*).

The Miño (Portug *M-nho*, the *Minus* of the Romans) is formed by the union of two small streams in the north of the province of Lugo, and flows first southwards, then on the whole south westwards to the Atlantic, forming in the lower part of its course the boundary between Spain and Portugal. It becomes navigable for small vessels at Salvaterra, 25 miles above its mouth. Large vessels cannot cross the bar at its mouth. Its only important tributary is the Sil (left), which at the confluence is the larger river of the two.

The Douro (Portug *Douro*, the *Durius* of the Romans) emerges from the rock as a small stream among the mountains of Urbiön on the borders of the provinces of Legroño and Soria, and, after describing a wide sweep to the east, flows westwards across the northern half of the Spanish tableland and across Portugal. For a distance of nearly 60 miles it forms the boundary between the two countries. It begins to be navigable 80 miles above its mouth, but sea going vessels ascend only to Oporto, and even so far, on account of a bar at the mouth, only at high tide. The principal tributaries on the right are the Pisuerga and Esla, on the left the Adaja, Tormes, and Coa (the last in Portugal).

The Guadiana (*s e*, *Wádi Ana*, the *Anas* of the ancients) was long believed to take its rise in the district known as the Campo do Montiel, where a string of small lakes known as the Lagunas de Rundera (partly in Ciudad Real, partly in Albacete) are connected by a stream which, on leaving the last of them, flows north westwards towards the Zancara and then disappears within two or three miles of that river. About 22 miles to the south west of the point of disappearance the stream was believed to re emerge in the form of several large springs which form a number of lakes at no great distance from the Zancara, and these lakes are hence known as the "eyes of the Guadiana" (*los ojos de Guadiana*). The small stream issuing from them is known as the Guadiana and soon joins the Zancara. It has now been ascertained, however, that the stream

which disappears higher up can have no such course, but that in fact its waters flow or trickle underground to the Zancara itself, which is therefore entitled to be regarded as the upper Guadiana. It has its source not far from that of the Júcar in the east of the plateau of La Mancha, and flows westwards till, under the name of the Guadiana, it turns south south west on the Portuguese frontier. In piercing the Sierra Morena it forms a series of foaming rapids, and it begins to be navigable only at Mertola, about 42 miles above its mouth.

The Guadalquivir (*s e*, *Wádi el Kébir*, "the great river," the *Betis* of the ancients), though the shortest of the great rivers of the Peninsula, is the only one that at all seasons of the year is a full-bodied stream, being fed in winter by the rains, in summer by the melting of the snows on the Sierra Nevada. What is regarded as the main stream rises in the Sierra de Cazorla in the east of the province of Jaén, but it does not become a considerable river till after it is joined by the Guadiana Menor (from the Sierra Nevada), on the left bank and the Guadalimar on the right. Lower down the principal tributary which it receives is the Jénil (left). In the days of the Moors the Guadalquivir was navigable for large vessels to Cordova, but, having been allowed to become silted up in the lower part of its course, it has only recently again been made navigable for vessels of 1200 tons burden to Seville.

The only considerable lakes in Spain are three coast lakes lagoons,—that of Albufera in the province of Valencia, the Mar Menor in Murcia, and the Laguna de la Janda in Cadiz behind Cape Trafalgar. Small alpine and other lakes are numerous, and small salt lakes are to be found in every steppe region.

The geological structure of the Spanish Peninsula is Geology comparatively simple. Upon a fundamental platform of ancient crystalline rocks, which had previously been upraised into detached ridges, a series of sedimentary formations was laid down, among which occur representatives of most of the geological systems from the older Palæozoic rocks up to those of Quaternary date. Arranged in order of age, with their respective areas, these various groups of rock are shown in the subjoined table —

	covering 49,477 sq. kilom., or 10.00 % of whole surface	
Quaternary		
Pliocene	9,084	1.80
Miocene and Oligocene	187,867	27.85
Eocene	23,564	4.80
Cretaceous	47,002	9.50
Jurassic	22,697	4.55
Triassic	22,443	4.45
Carboniferous	11,801	2.32
Devonian	5,780	1.10
Silurian (and Cambrian)	114,882	23.18
Archæan	1,694	0.33
Eruptive rocks of various ages	49,665	10.00

Archæan rocks are exposed in the northern half of the Peninsula, particularly along the great Pyrenean axis, in Galicia, Estremadura, the Sierra Morena, the Sierra Nevada, and Serranía de Ronda. They consist of granites, gneisses, and mica schists, with talcschists, amphibolites, and crystalline limestones. The oldest Palæozoic strata are referred, from their included fossils, to the Cambrian and Silurian divisions. They range through a vast region of Andalusia, Estremadura, Castile, Salamanca, Leon, and Asturias, and along the flanks of the Pyrenean and Cantabrian chain. They consist of slates, greywackes, quartzites, and diabases. Grits, quartzites, and shales referable to the Devonian system occur in a few scattered areas, the largest and most fossiliferous of these occurring in the Asturias. The Carboniferous rocks of Spain are divisible into three groups, the lowest consisting of limestones with sandstones and shales, the middle of conglomerates and sandstones, and the upper of sandstones, conglomerates, shales, and coals. They lie in detached basins, and have not yet been well explored. One of these areas covers a considerable space in the Asturias, whence it stretches more or less continuously through the provinces of Leon, Palencia, and Santander, covering altogether an area of 6500 square kilometres. Another tract occurs at San Juan de las Abadesas in Catalonia, where it occupies about 200 square kilometres, while a third, about 500 square kilometres in extent, runs from the province of Cordova into that of Badajoz. There are other smaller areas containing little or no coal, but showing by the included plant remains that the strata undoubtedly belong to the Carboniferous system.

The Triassic system is well developed in the north of the Peninsula along the Cantabrian chain and eastwards to the Mediterranean. It is composed of red and variegated sandstones, dolomites, and marls, traversed in some places by ophiolite rocks, and containing deposits of gypsum, aragonite, and rock salt. These strata are overlain by members of the Jurassic series, which are especially conspicuous in the eastern part of the Peninsula.

between Castile and Aragon, along the Mediterranean border, in Andalusia, and likewise along the flanks of the Pyrenees. The Lias is best represented. The Cretaceous system is distributed in four great districts: the largest of these extends through the kingdoms of Murcia and Valencia, a second stretches between the two Castiles, a third is found in the Basque Provinces and the Asturias, and a fourth spreads out along the southern slopes of the Pyrenees from Navarre to the Mediterranean. The lower members of the Cretaceous series include an important freshwater formation (sandstones and clays), which extends from the Cantabrian coast through the provinces of Santander, Burgos, Soria, and Logroño, and is supposed to represent the English Wealden series. The higher members comprise massive hippurite limestones, and in the Pyrenean district representatives of the upper subdivisions of the system, including the Danian.

Deposits of Tertiary age cover rather more than a third of Spain. They are divisible into two great series, according to their mode of origin in the sea or in fresh water. The marine Tertiary accumulations commence with those that are referable to the Eocene series, consisting of nummulite limestones, marls, and siliceous sandstones. These strata are developed in the basin of the Ebro, and in a belt which extends from Valencia through Murcia and Andalusia to Cadiz. Marine Miocene deposits occupy some small tracts, especially on the coast of Valencia. But most of the sandy Tertiary rocks of that district are Pliocene. The Tertiary masses of Andalusia have coarse conglomerates (Middle Miocene) at their base, followed by thick beds of Bryozoa molasse and younger (Pliocene) beds. These strata are specially noteworthy for containing an important metalliferous deposit, that of the native silver of Herrerías, which is found in a Pliocene bed in the form of flakes, needles and crystals. But the most extensive and interesting Tertiary accumulations are those of the great lakes which in Oligocene and Miocene time spread over so large an expanse of the tableland. These sheets of fresh water covered the centre of the country, including the basins of the Ebro, Júcar, Guadalquivir, Guadalquivir, and Tagus. They have left behind them thick deposits of clays, marls, gypsum, and limestone, in which numerous remains of the land animals of the time have been preserved.

Quaternary deposits spread over about a tenth of the area of the country. The largest tract of them is to be seen to the south of the Cantabrian chain, but another, of hardly inferior extent, flanks the Sierra de Guadarrama, and spreads out over the great plain from Madrid to Cáceres. Some of these alluvial accumulations indicate a former greater extension of the snowfields that are now so restricted in the Spanish sierras. Remains of the reindeer are found in caves in the Pyrenees.

Eruptive rocks of many different ages occur in different parts of Spain. The most important tract covered by them is that which stretches from Cape Ortegal to Coria in Estremadura and spreads over a large area of Portugal. They likewise appear in Castile, forming the sierras of Gredos and Guadarrama, farther south they rise in the mountains of Toledo, in the Sierra Morena, and across the provinces of Cordova, Seville, Huelva, and Badajoz as far as Huelva in Portugal. Among the minor areas occupied by them may be especially mentioned those which occur in the Triassic districts. Of rocks included in the eruptive series the most abundant is granite. There occur also quartz porphyry (Sierra Morena, Pyrenees, &c.), diorite, porphyrite, diabase (well developed in the north of Andalusia, where it plays a great part in the structure of the Sierra Morena), ophiolite (Pyrenees, Cadiz), serpentine (forming an enormous mass in the Sierra de Ronda), trachyte, liparite, andesite, basalt. The last four rocks occur as a volcanic series distributed in three chief districts—that of Cape Gata, including the south east of Andalusia and the south of Murcia, that of Catalonia, and that of La Mancha.

Climate.

Climate.—In accordance with its southerly position, its differences of elevation, and the variety in its superficial configuration in other respects, Spain presents within its borders examples of every kind of climate to be found on the northern hemisphere, with the sole exception of that of the torrid zone. As regards temperature, the heart of the tableland is characterized by extremes as great as are to be met with in almost any part of central Europe. The northern and north western maritime provinces, on the other hand, have a climate as equable, and, it may be added, as moist, as that of the west of England or Scotland.

Four zones of climate are distinguished. The first zone may be called that of the tableland, although to it also the greater part of the Ebro basin may be referred. This is the zone of the greatest extremes of temperature. Even in summer the nights are often decidedly cold, and on the high parameras it is not a rare thing to see hoar frost in the morning. In spring cold wetting mists occasionally envelop the land for entire days, while in summer the sky is often perfectly clear for weeks together. At all seasons of the year sudden changes of temperature, to the extent of from 30° to 50° F., are not infrequent. The air is extremely dry, which is all the more keenly felt from the fact that it is almost constantly in motion. At Madrid (2150 feet above sea level) it regularly

freezes so hard in December and January that skating is carried on on the sheet of water in the Buen Retiro, and, as winter through out Spain, except in the maritime provinces of the north and north west, is the season of greatest atmospheric precipitation, snowfalls are frequent, though the snow seldom lies long except at high elevations. The summers, on the other hand, are not only extremely warm but almost rainless, the sea-winds being deprived of their moisture on the edge of the plateau. In July and August the plains of New Castile and Estremadura are sun burnt wastes, the roads are several inches deep with dust, the leaves of the few trees are withered and discoloured, the atmosphere is filled with a fine dust, producing a haze known as *calina*, which converts the blue of the sky into a dull grey. In the greater part of the Ebro basin the heat of summer is even more intense. The treeless mostly steppe like valley with a bright-coloured soil acts like a concave mirror in reflecting the sun's rays, and, moreover, the mountains and highlands by which the valley is enclosed prevent to a large extent the access of winds, and thus hinder the renewal of the air, which in the lowest parts is little disturbed.

The second zone is that of the Mediterranean provinces, exclusive of those of the extreme south. In this zone the extremes of temperature are less, though the summers here also are warm, and the winters decidedly cool, especially in the north east.

The southern zone, to which the name of African has been given, embraces the whole of Andalusia as far as the Sierra Morena, the southern half of Murcia, and the province of Alicante. In this zone there prevails a genuine subtropical climate, with extremely warm and almost rainless summers and mild winters, the temperature hardly ever sinking below freezing-point. The hottest part of the region is not the most southerly district but the bright-coloured steppes of the coast of Granada, and the plains and hill terraces of the south-east coast from Almería to Alicante. Snow and frost are here hardly known. It is said that at Málaga snow falls only about once in twenty five years. The winter, in fact, is the season of the brightest vegetation after the long drought of summer the surface gets covered once more in late autumn with a fresh green varied with bright coloured flowers, and so it remains the whole winter through. On the other hand, the eastern part of this zone is the part of Spain which is liable to be visited from time to time by the scorching and blasting *leveche*, the name given in Spain to the sirocco, as well as by the *solano*, a moist and less noxious east wind.

The fourth zone, that of the north and north west maritime provinces, presents a marked contrast to all the others. The temperature is mild and equable, the rains are abundant all the year round, but fall chiefly in autumn, as in the west of Europe generally. Monthly roses bloom in the gardens at Christmas as beautifully and as plentifully as in summer. The chief drawback of the climate is an excess of rain in some parts, especially in the west. Santiago de Compostella, for example, has one of the highest rainfalls on the mainland of Europe (see table below).

The figures given in the following table (I),¹ although based only on data of short periods (from 3½ to 20 years), will help to illustrate the preceding general remarks. Greenwich is added for the sake of comparison.

Station		Height in feet	Mean Temperature, F			Rain fall in inches
			Jan	July	Year	
Tableland zone	Leon	2600	37°	73°	53°	19
	Madrid	2150	41	76	56	15
Southern zone	San Fernando	90	52	75	63	30
	Malaga	76	54	79	70	
Mediterranean zone	Murcia	140	49	79	68	14
	Mahon		52	77	64	27
Northern maritime zone	Bilbao	50	46	70	58	46
	Oviedo	750	43	66	54	36
	Santiago	750	45	66	55	66
Greenwich			39	63	50	25

Vegetation.—The vegetation of Spain exhibits a variety in keeping with the differences of climate just described. The number of endemic species is exceptionally large, the number of monotypic genera in the Peninsula greater than in any other part of the Mediterranean domain. The endemic species are naturally most numerous in the mountains, and above all in the loftiest ranges, the Pyrenees and the Sierra Nevada, but it is a peculiarity of the Spanish tableland, as compared with the plains and tablelands of central Europe, that it also possesses a considerable number of endemic plants and plants of extremely restricted range. This fact, however, is also in harmony with the physical conditions above described, being explained by the local varieties, not only of climate, but also of

¹ By conversion from Th. Fischer's *Klima der Mittelmeerländer*

soil Altogether no other country in Europe of equal extent has so great a wealth of species as Spain According to the *Prodromus Floræ Hispaniæ* of Willkomm and Lange (completed in 1880), the number of species of vascular plants then ascertained to exist in the country was 5096

Spain may be divided botanically into four provinces, corresponding to the four climatic zones

In the tableland province (including the greater part of the Ebro valley) the flora is composed chiefly of species characteristic of the Mediterranean region, generally of species confined to the Peninsula. A peculiar character is imparted to the vegetation of this province by the growth over large tracts of evergreen shrubs and large herbaceous plants belonging to the *Cistaceæ* and *Labiateæ*. Areas covered by plants of the former group are known to the Spaniards as *jarales*, and are particularly extensive in the Mancha Alta and on the slopes of the Sierra Morena, where the *ladanum* bush (*Cistus ladaniferus*) is specially abundant, those covered by plants of the latter group are known as *tomillares* (from *tomillo*, thyme), and occur chiefly in the south, south west, and east of the tableland of New Castile In the central parts of the same tableland huge thistles (such as the *Onopordum nererosum*), centaureas, artemisias, and other *Compositæ* are scattered in great profusion From the level parts of these tablelands trees are almost entirely absent. On the lofty pyramides of Sierra and other parts of Old Castile the vegetation has an almost alpine character

The southern or African province is distinguished chiefly by the abundance of plants which have their true home in North Africa (a fact easily understood when we consider the geologically recent land connexion of Spain with that continent), but is also remarkable for the occurrence within it of numerous Eastern plants (natives of Syria and Asia Minor), and plants belonging to South Africa and the Canaries, as well as natives of tropical America which have become naturalized here (see below under *Agriculture*) In this province the maritime parts of Malaga and Granada present scenes of almost tropical richness and beauty, while, on the other hand, in Murcia, Alicante, and Almería the aspect is truly African, fertile oases appearing in the midst of rocky deserts or barren steppes. A peculiar vegetation, consisting mainly of low shrubs with fleshy glaucous leaves (*Juula crithmoides*, &c.), covers the marismas of the Guadalquivir and various parts of the south west coast where salt marshes prevail Everywhere on moist sandy ground are to be seen tall thickets of *Arundo Donax*.

The Mediterranean province is that in which the general aspect of the vegetation agrees most closely with that of southern France and the lowlands of the Mediterranean region generally On the lower slopes of the mountains and on all the parts left uncultivated the prevailing form of vegetation consists of a dense growth of shrubs with thick leathery leaves, such as are known to the French as *maquis*, to the Italians as *macchie*, and are called in Spanish *monte bajo*,¹ shrubs which, however much they resemble each other in external appearance, belong botanically to a great variety of families

The northern maritime province, in accordance with its climate, has a vegetation resembling that of central Europe Here only are to be found rich grassy meadows adorned with flowers such as are seen in English fields, and here only do forests of oak, beech, and chestnut cover a large proportion of the area The extraordinary abundance of forus (as in western France) is likewise characteristic

sts The forest area of Spain generally is relatively small The whole extent of forests is estimated at little more than 3 millions of hectares (7½ million acres), or less than 6 per cent of the area of the kingdom Evergreen oaks, chestnuts, and conifers are the prevailing trees. The cork oaks of the southern provinces and of Catalonia are of immense value, but the groves containing this tree have suffered greatly from the reckless way in which the product is collected Among other characteristic trees are the Spanish pine (*Pinus hispanica*), the Corsican pine (*P. Laricio*), the Pinsapo fir (*Abies Pinsapo*), and the *Quercus Toza*, the last belonging to the slopes of the Sierra Nevada Besides the date palm the dwarf palm grows spontaneously in some parts of the south, but it nowhere makes up a large element of the vegetation

pes. The Spanish steppes deserve a special notice, since they are not confined to one of the four botanical provinces, but are found in all of them except the last Six considerable steppe regions are counted — (1) that of Old Castile, situated to the south of Valladolid, and composed chiefly of hills of gypsum, (2) that of New Castile, in the south east (the district of La Mancha), (3) the Aragonese, occupying the upper part of the basin of the Ebro, (4) the littoral, stretching along the south east coast from Alicante to the neighbourhood of Almería, (5) the Graudine, in the east of Upper Andalusia (the former kingdom of Granada), and (6) the Betic, in Lower Andalusia, on both sides of the valley of the Jemil All of these are originally salt steppes, and, where the soil is still highly unimpregnated with salt, have only a sparse covering of shrubs,

mostly members of the *Salsolaceæ*, with thick, greyish green, often downy leaves A different aspect is presented by the grass steppes of Murcia, La Mancha, the plateaus of Guadix and Huescar in the province of Granada, &c., all of which are covered chiefly with the valuable esparto grass (*Macrochloa tenacissima*)

Fauna — The Iberian Peninsula belongs to the Mediterranean Fauna, subregion of the Palearctic region of the animal kingdom, a division which includes also the north of Africa. The forms that betray African affinities are naturally to be found chiefly in the south Among the mammals that fall under this head are the common genet (*Genetta vulgaris*), which extends, however, pretty far north, and is found also in the south of France, the fallow deer, the porcupine (very rare), and a species of ichneumon (*Ichneumon viddringtoni*), which is confined to the Peninsula, and is the only European species of this characteristically African genus The magot or Barbary ape (*Inuus caudatus*), the only species of monkey still found wild in Europe, is also a native of Spain, but the only flock still surviving, on the rock of Gibraltar, has often been on the point of extinction, and has to be renewed from time to time by importations from the north of Africa. Of the mammals in which Spain shows more affinity to the fauna of central and northern Europe, some of the most characteristic are the Spanish lynx (*Lynx pardinus*), a species confined to the Peninsula, the Spanish hare (*Lepus madrilensis*), and the species mentioned in the article *PARENES* The birds of Spain are very numerous, partly no doubt in consequence of the fact that the Peninsula lies in the route of those birds of passage which cross from Africa to Europe or Europe to Africa by way of the Straits of Gibraltar Many species belonging to central Europe pass the winter in Spain, especially on the south eastern coasts and in the valley of the Guadalquivir Innumerable, for example, are the snipes which in that season are killed in the latter district and brought to the market of Seville Among the birds of prey may be mentioned, besides the numerous and bearded vultures, the Spanish vulture (*Gyps occidentalis*), the African or Egyptian vulture (*Neophron percnopterus*), which is found among all the mountains of the Peninsula, the Spanish imperial eagle (*Aquila adalberti*), the short toed eagle (*Circæus gallicus*), the southern eagle-owl (*Bubo atheniensis*), besides various kites and falcons Among gallinaceous birds, besides the red legged partridge, which is met with everywhere on the steppes, there are found also the *Pterocles alchida* and *P. arenarius*, and from among the birds of other orders the southern shrike (*Lanius meridionalis*), the Spanish sparrow (*Passer cyaneus*), and the blue magpie (*Cyanopica cooki*) may be singled out as worthy of mention The last is highly remarkable on account of its distribution, it being confined to Spain while the species most closely allied to it (*Cyanopica cyanea*) belongs to the east of Asia The flamingo is found native in the Balearic Islands and on the southern coasts, and occasionally a stray specimen is to be seen on the tableland of New Castile Other birds peculiar to the south are two species of quails, the Andalusian hemipode (*Turnix sylvatica*), confined to the plains of Andalusia, the southern shearwater (*Puffinus cinereus*), and other water birds. Amphibians and reptiles are particularly numerous in the southern provinces, and among these the most remarkable are the large southern or eyed lizard (*Lacerta ocellata*), which sometimes attains 3 feet in length and is very abundant, the *Platydictylus saccularius*, the grey amphibia (*Blanus cinereus*), the European pond tortoise (*Emys europæa*), and another species, *Emys segrizii* Insect life is remarkably abundant and varied More than 350 species of butterflies, many of them endemic, have been counted in the province of Madrid alone Besides the ordinary European scorpion, which is generally distributed in southern Europe, there is another species, the sting of which is said to be still more severe, found chiefly in the basin of the Ebro Trout abound in the mountain streams and lakes, barbel and many other species of *Cyprindæ* in the rivers of the plains. For the sea fauna, see under *Fisheries* below

Extent — The total area of the mainland of Spain, according to the calculations of Strelbitsky, is 495,612 square kilometres or 191,365 square miles, that of the Balearic Islands 4982 square kilometres or 1923 square miles, and that of the Canary Islands, which, though belonging geographically to Africa, are administratively associated with the kingdom of Spain, 7611 square kilometres or 2939 square miles, so that the total area of the kingdom is 508,205 square kilometres or 196,225 square miles This total agrees pretty closely with that in Justus Perthes's table given below (Table II), although considerable differences will be observed in the areas assigned to the mainland provinces and the two island groups respectively The length of the coast line of the mainland, according to Strelbitsky, is 2662 miles, which is equivalent to 1 mile of coast for every 72 square miles of area, about the same proportion as in France. The greatest length from north east to south west is 420 miles

Territorial Divisions and Population — For administrative purposes the kingdom of Spain has since 1833 been divided into forty administrative provinces, forty seven of which belong to the mainland divisions.

¹ As distinguished from *monte alto*, the collective name for forest trees.

Before 1833 the mainland was divided into thirteen provinces, also enumerated below, which took their names from the ancient kingdoms and principalities out of which the modern kingdom was gradually built up. The present provinces are subdivided into judicial districts (*partidos judiciales*) and communes (*municipios*).

Popula-
tion.

It is probable that the population of Spain attained its highest development during the period of the early Roman empire, when it has been estimated, though of course on imperfect data, to have numbered forty or fifty millions. The best evidence of a dense population in those days is that afforded by the specific estimates of ancient writers for some of the larger cities. The population of Tarraco (Tarragona) was estimated at 21 millions, and that of Nova Carthago (Cartagena), Italica (Sevilla la Vieja), and others at several hundreds of thousands. Ementia Augusta (Merida) had a Roman garrison of 90,000 men, which also implies a large population.¹

Table II.—Area and Population of the Former and Present Provinces.

Provinces.	Area in Square Miles.	Population 1857.	Population Dec. 31, 1877.	Increase or Decrease.	Pop. per sq. m. 1877.
NEW CASTILE.	29,018	1,477,816	1,627,131	+ 10.1	56
Madrid	2,007	475,753	541,164	+ 14.3	13
Guadalajara	4,482	100,003	112,000	+ 11.4	41
Toledo	5,356	225,700	250,000	+ 10.9	47
Cuenca	6,723	100,000	110,000	+ 10.0	21
Ciudad Real	7,810	244,223	260,000	+ 6.6	33
OLD CASTILE.	25,409	1,609,948	1,850,718	+ 15.5	73
Burgos	5,031	222,000	252,000	+ 13.5	50
León	1,841	173,512	174,423	+ 0.5	59
Santander	2,112	214,441	220,000	+ 2.6	111
Vizcaya	2,702	184,000	190,000	+ 3.3	69
Segovia	2,714	146,500	150,000	+ 2.4	55
Soria	3,550	140,000	150,000	+ 7.1	40
Palencia	3,125	150,000	160,000	+ 6.7	51
Valladolid	5,443	244,000	260,000	+ 6.6	48
ARAGON.	4,091	524,529	578,352	+ 10.3	140
Orléans	4,091	524,529	578,352	+ 10.3	140
LEON.	15,242	861,430	885,625	+ 2.8	57
Salamanca	4,400	223,517	220,000	- 1.6	50
Zamora	4,100	241,169	240,000	- 0.5	59
León	6,742	243,753	260,000	+ 6.7	57
ESTREMADURA.	16,702	707,115	739,403	+ 4.6	44
Badajoz	8,000	404,000	420,000	+ 4.0	52
Caceres	8,702	303,115	319,403	+ 5.4	37
 GALICIA.	11,343	1,778,879	1,808,027	+ 1.6	163
Orense	2,673	401,000	400,000	- 0.2	150
Lugo	2,673	401,000	400,000	- 0.2	150

¹ *Guizot, La Espagne Contemporaine* I. 459

The first Spanish census was made in 1504, but some of the provinces not included in the enumeration were for one reason or another not embraced in the enumeration, so that the total population assigned to Spain within its present limits for that date is obtained by adding the results of enumerations at different dates in the provinces then excluded. The total thus arrived at is 8,205,791. No other census took place till 1787, when the total was found to be 10,265,150, and this census was followed by another in 1797, when the population was returned as 10,541,221. Various estimates were made within the next sixty years, but the census of 1857 proved that some of these estimates must have been greatly below the truth. The total population then ascertained to exist in Spain was 15,464,340, an increase of not much less than 50 per cent. since the census of 1797. The last census took place on December 31, 1877, and the total population then ascertained, 16,831,859, shows an increase of only 7½ per cent., equal to an annual increase at the rate of 0.35 per cent.—lower than in any other country in Europe except France.

As Table II. shows, the density of population in Spain as a whole is little more than that of the most thinly peopled country of England in 1881 (Westmoreland, 82 to the square mile). Looking at the old provinces, we find that the most thickly peopled are all maritime, and that all the maritime provinces except Andalusia and Murcia have a density exceeding 100 to the square mile. The most densely peopled province of all is not Catalonia, in which manufacturing industries are so highly developed, nor the Basque Provinces with their great iron industry, but Galicia, where there are neither manufactures nor minerals to speak of, but where tillage occupies a relatively larger area than anywhere else in Spain. Of the modern provinces the most thinly peopled are Cuenca and Ciudad Real, in the barren region of the east and south of New Castile, and Albacete in the Murcian steppe, in each case the density being less than half of that of the most thinly peopled English county. The column indicating the increase (or decrease) per cent. of the population between 1857 and 1877 shows that, outside of the province in which the capital is situated, the increase points chiefly to the recent development of manufactures and mining,—to the development of copper mines in Huelva, lead mines in Jaen, iron mines in Vizcaya, cotton manufactures in Barcelona. In Murcia it points no doubt to the great development of the trade in esparto as well as in southern fruits. On the other hand the decrease in Lérida and Girona indicates how the attraction of higher wages in the manufacturing districts of Catalonia tends to deplete the neighbouring country districts.

As regards the distribution of population between town and country, Spain contrasts in a marked manner with Italy, Spain having but few large towns and a relatively large country population. In 1877 there were only five towns with more than 100,000 inhabitants—Madrid (397,816), Barcelona (248,943), Valencia (143,861), Seville (134,313), and Málaga (115,552). Only nine had a population between 50,000 and 100,000, and besides these only 171 had a population above 10,000.

The birth rate in Spain is 33.9 per thousand as against 35.1 in England and Wales, the death rate 20.1 (21.4 in England and Wales), the number of marriages per thousand inhabitants was 7.32 (8.05 in England and Wales). The percentage of illegitimacy is 5.6. The number of males born for every 100 females averages 107, a higher proportion than in any other country of Europe for which statistics are obtainable except Greece (112), and Roumania (111).

Foreign Possessions.—The population of the principal foreign possessions of Spain in 1877 numbered 7,822,122, made up as follows:—

Cuba	1,521,684	Philippine Islands	5,567,655
Porto Rico	731,618	Fernando Po	1,106

Besides the Philippine Islands in the Eastern Archipelago, Spain possesses the greater part of the Sulu Archipelago, and, in the Pacific, the Marianne, Pelew, and Caroline Islands. Off the Guinea coast she possesses the Island of Annobon as well as that of Fernando Po, and on the coast itself the district round Corisco Bay. She has likewise declared a protectorate over the West African coast between Capes Bojador and Blanco (desert of Sahara). The presidios, whose population is given in Table II., are Peñon de Velez, Alhucemas, and Melilla (besides Ceuta).

Agriculture.—Agriculture is by far the most important Spanish industry, nearly 73 per cent. of those whose occupations were classified at the census of 1877 being entered under that head. In general it is in a backward condition, and is now much less productive than in the time of the Romans and again under the Moors. The expulsion of the latter people in many places inflicted upon agriculture a blow from which it has not recovered to this day. Aragon and Estremadura, the two most thinly peopled of all the old provinces, and the eastern half of Andalusia (above Seville),

² In all these cases the figures for Spain are the means of the years 1855-70 and 1870-83 inclusive.

have all suffered particularly in this manner, later occupiers never having been able to rival the Moors in overcoming the sterility of nature, as in Aragon, or in taking advantage of its fertility, as in Andalusia and the Tierra de Barros. The implements in general use are of the rudest description. The plough is merely a pointed stick shod with iron, crossed by another stick which serves as a share, scratching the ground to the depth of a few inches. But the regular import now of agricultural implements (chiefly from England and France) betokens an improvement in this respect. In general there has been considerable improvement in the condition of agriculture since the introduction of railways, and in every province there is a royal commissioner entrusted with the duty of supervising and encouraging this branch of industry. Among other institutions for the promotion of agriculture the royal central school at Aranjuez, to which is attached a model farm, is of special importance.

The provinces in which agriculture is most advanced are those of Valencia and Catalonia, in both of which the river valleys are thickly sown with irrigation canals and the hill slopes carefully terraced for cultivation. In neither province is the soil naturally fertile, and nothing but the untiring industry of the inhabitants, favoured in the one case by the rivers which traverse the province from the tableland of New Castile and the numerous small streams (*nacimiento*s) that issue from the base of the limestone mountains of which the province is largely composed, and in the other case by the numerous torrents from the Pyrenees, has converted them into two of the most productive regions in Spain. In the Basque Provinces and in Galicia the cultivable area is quite as fully utilized, but in these the difficulties that have to be contended with are not so great. The least productive tracts, apart from Aragon and Estremadura, are situated in the south and east of New Castile, in Murcia, and in Lower Andalusia—the marshes or *marismas* of the lower Guadalquivir and the *arcues gordas* between that river and the Rio Tinto. By far the greater part of the tableland, however, is anything but fertile, the principal exceptions being the Tierra de Campos, said to be the chief corn growing district in Spain, occupying the greater part of Valencia in the north-west of Old Castile, and the Tierra de Barros, in the portion of Badajoz lying to the south of the Guadiana in Estremadura, another district noted for its corn.

Except in Leon and the provinces bordering on the Bay of Biscay and the Atlantic irrigation is almost everywhere necessary for cultivation, at least in the case of certain crops. Almost all kinds of vegetables and garden fruits, oranges, rice, hemp, and other products are generally grown solely or mainly on irrigated land, whereas most kinds of grain, vines, and olives are cultivated chiefly on dry soil. The water used for irrigation is sometimes derived from springs and rivers in mountain valleys, whence it is conveyed by long canals (*acequias*) along the mountain sides and sometimes by lofty aqueducts to the fields on which it is to be used. Sometimes the water of entire rivers or vast artificial reservoirs (*plantanos*) is used in feeding a dense network of canals distributed over plains many square miles in extent. Such plains in Valencia and Murcia are known by the Spanish name of *huertas* (gardens), in Andalusia by the Arabic name of *tegas*, which has the same meaning. Many of the old irrigation works,—such, for example, as those of the plain of Tarragona,—date from the time of the Romans, and many others from the Moorish period, while new ones are still being laid out at the present day. Where no running water is available for irrigation, water is often obtained from wells by means of waterwheels (*norias*) of simple construction. In most cases such wheels merely have earthenware pitchers attached to their circumference by means of strips of esparto, and are turned by a horse harnessed to a long arm fitted to a revolving shaft. In recent years many artesian wells have been sunk for irrigation. According to Higgin (see Bibliography), the total area of irrigated land in Spain amounts to 4439 square miles. The effect of irrigation is shown by the fact that the irrigated portion of Murcia has a population of 1681 to the square mile as against 101 for the whole province, and Orihuela a population of 767 to the square mile as against 194 for the whole province of Alicante to which it belongs.

cereals.

Cereals constitute the principal object of cultivation, and among these wheat ranks first, the next in importance being barley, the chief fodder of horses and mules. Both of these grains are cultivated in all parts—on the plains as well as among the mountains, but chiefly on the more level parts of the two Castiles and Leon, and on the plains of the basin of the Guadalquivir. Oats and rice are cultivated only in the higher parts of the mountains, the former as a substitute for barley in feeding horses and mules, the latter as a breadstuff. Maize also is cultivated in all the provinces, nevertheless the total extent of its cultivation is limited, since, being a summer crop, it requires irrigation except in the Atlantic provinces, and other products generally yield a more profitable return where irrigation is pursued. Rice is cultivated on a large scale only in Valencia. Among cereals of less importance are buckwheat (in the mountainous regions of the

north), millets, including both the common millet (*Panicum miliaceum*) and the so-called Indian millet (*Sorghum vulgare*, the *jodro* of India, the *durrah* of Africa), and even (in La Mancha) guinea corn (*Penicillaria spicata*). As to the quantity of cereals produced in the country we are without official information, and the estimates of the average annual production of cereals of all kinds are very discrepant, varying from 250 to 430 million bushels. The average production of wheat alone has been estimated at 177 million bushels, and the average produce of that crop per acre at 11.13 bushels (that of England being about 29 bushels). If these figures can be taken as approximately correct, it follows that the average acreage under wheat in Spain is nearly 16 million acres, or between five and six times the average in Great Britain, which has less than half the area of Spain. The produce per acre just indicated places Spain among those countries of Europe in which the return is least, which is probably fully accounted for by the backward state of cultivation generally and in particular by the small expenditure on manure. As a rule, in fact, the straw left on the ground is the only manure which the land receives.

The cereal and especially the wheat production of the country regularly furnishes a considerable export. During the five years 1879–83 the value of the export of cereals and pod fruits of all kinds was nearly 3 per cent of the total value of the exports, but this export is balanced by a large import, especially of wheat flour. In bad years, indeed, the value of the import under this head greatly exceeds that of the export.

In the production of pod fruits and kitchen vegetables Spain is ahead of all other countries in Europe. The chick pea forms part of the daily food of all classes of the inhabitants, and among other pod fruits largely cultivated are various kinds of beans and peas, lentils (*Ervum lens*), Spanish lentils (*Lathyrus sativus*) and other species of *Lathyrus*, lupines, &c. The principal fodder crops are lucerne (*Medicago sativa*) and esparcotte (a variety of sainfoin). Clover, particularly crimson clover (*Trifolium incarnatum*), is grown in the northern provinces. Among vegetables garlic and onions take the chief place, and form an indispensable part of the diet of all Spaniards, besides these, tomatoes and Spanish pepper are the principal garden crops. It is open such crops that the Spanish peasant in general bestows his chief care

As regards the quantity of the product wine comes next after Wine.

cereals among the objects of cultivation in Spain. Here again we are dependent only upon vague estimates of the average amount produced, but usually the average annual Spanish production of wine is estimated at between 440 and 500 million gallons, an estimate which places Spain third (next after France and Italy) among the wine producing countries of Europe. So far as quantity is concerned the principal wine producing districts are in the north-east, but the only wines of Spain which have a world wide reputation are those of the south, and more particularly those which take the name of "sherry," from the town of Jerez, in the neighbourhood of which they are grown. The total area under the vine is estimated at about 3,480,000 acres (or about 2.8 per cent of the entire surface), and of this total about 772,700 acres belong to the Catalonian provinces, chiefly Barcelona. The provinces which produce most wine are Barcelona, Saragossa, Cadiz, and Malaga, the annual amount of the production being in the order in which the provinces are mentioned.

The official tables distinguish the wines exported from Spain as common wines, sherry and similar wines, and other full bodied wines (*vino generoso*). The returns of recent years, as will be seen from Table III given below, show that of late an enormous increase has taken place in this export both as regards quantity and value, this increase being chiefly due to the extension of the export of the commoner wines to France by way of Barcelona.

	Average of Five Years 1874–78		Average of Five Years 1879–83		1884	
	Thousands of Gallons exported.	Value in thousands of Pounds.	Thousands of Gallons exported.	Value in thousands of Pounds.	Thousands of Gallons exported.	Value in thousands of Pounds.

Total	49,214	5,483	142,824	10,764	183,420	10,815

There is also a large export of grapes and raisins, especially from the southern provinces (Malaga and Almeria). The average quantity of the two together exported in each of the five years

¹ In an article by M. P. A. Delboy in the *Journal of the Statistical Society* for March 1884, translated from the *Journal de la Société de Statistique de Paris*, September 1883.

Before 1833 the mainland was divided into thirteen provinces, also enumerated below, which took their names from the ancient kingdoms and principalities out of which the modern kingdom was gradually built up. The present provinces are subdivided into judicial districts (*partidos judiciales*) and communes (*ayuntamientos*).

It is probable that the population of Spain attained its highest development during the period of the early Roman empire, when it has been estimated, though of course on imperfect data, to have numbered forty or fifty millions. The best evidence of a dense population in those days is that afforded by the specific estimates of ancient writers for some of the larger cities. The population of Tarraco (Tarragona) was estimated at 2½ millions, and that of Nova Carthago (Cartagena), Italica (Sevilla la Vieja), and others at several hundreds of thousands. Emerita Augusta (Merida) had a Roman garrison of 90,000 men, which also implies a large population.¹

¹ Garrido, *La España Contemporánea*, I, 489

The first Spanish census was made in 1594, but some of the provinces now included in the kingdom were for one reason or another not embraced in the enumeration, so that the total population assigned to Spain within its present limits for that date is obtained by adding the results of enumerations at different dates in the provinces then excluded. The total thus arrived at is 8,206,791. No other census took place till 1787, when the total was found to be 10,268,150, and this census was followed by another in 1797, when the population was returned as 10,541,221. Various estimates were made within the next sixty years, but the census of 1857 proved that some of these estimates must have been greatly below the truth. The total population then ascertained to exist in Spain was 15,464,340, an increase of not much less than 50 per cent since the census of 1797. The last census took place on December 31, 1877, and the total population then ascertained, 18,631,889, shows an increase of only 7½ per cent, equal to an annual increase at the rate of 0.35 per cent.—lower than in any other country in Europe except France.

As Table II shows, the density of population in Spain as a whole is little more than that of the most thinly peopled county of England in 1881 (Westmoreland, 82 to the square mile). Looking at the old provinces, we find that the most thickly peopled are all maritime, and that all the maritime provinces except Andalusia and Murcia have a density exceeding 100 to the square mile. The most densely peopled province of all is not Catalonia, in which manufacturing industries are so highly developed, nor the Basque Provinces with their great iron industry, but Gales, where there are neither manufactures nor minerals to speak of, but where tillage occupies a relatively larger area than anywhere else in Spain. Of the modern provinces the most thinly peopled are Cuenca and Ciudad Real, in the barren region of the east and south of New Castile, and Albacete in the Murcian steppe, in each case the density being less than half of that of the most thinly peopled English county. The column indicating the increase (or decrease) per cent. of the population between 1857 and 1877 shows that, outside of the provinces in which the capital is situated, the increase points chiefly to the recent development of manufactures and mining,—to the development of copper mines in Huelva, lead mines in Jaén, iron mines in Vizcaya, cotton manufactures in Barcelona. In Murcia it points no doubt to the great development of the trade in spirits as well as in southern fruits. On the other hand the decrease in Lerida and Gerona indicates how the attraction of higher wages in the manufacturing districts of Catalonia tends to deplete the neighbouring country districts.

As regards the distribution of population between town and country, Spain contrasts in a marked manner with Italy, Spain having but few large towns and a relatively large country population. In 1877 there were only five towns with more than 100,000 inhabitants—Madrid (397,816), Barcelona (248,943), Valencia (143,861), Seville (134,318), and Malaga (115,882). Only nine had a population between 50,000 and 100,000, and besides these only 171 had a population above 10,000.

The birth rate in Spain is 33.9 per thousand as against 35.1 in England and Wales, the death rate 29.1 (21.4 in England and Wales), the number of marriages per thousand inhabitants was 7.32 (8.08 in England and Wales). The percentage of illegitimacy is 5.6. The number of males born for every 100 females averages 107, a higher proportion than in any other country of Europe for which statistics are obtainable except Greece (112) and Roumania (111).

Foreign Possessions.—The population of the principal foreign possessions of Spain in 1877 numbered 7,822,123, made up as follows—

Cuba	1,521,684	Philippine Islands	5,567,685
Porto Rico	731,648	Fernando Po	1,106

Besides the Philippine Islands in the Eastern Archipelago, Spain possesses the greater part of the Sulu Archipelago, and, in the Pacific, the Mariana, Pelew, and Caroline Islands. Off the Guinea coast she possesses the Island of Annobon as well as that of Fernando Po, and on the coast itself the district round Corisco Bay. She has likewise declared a protectorate over the West African coast between Capes Bojador and Blanco (desert of Sahara). The presidios, whose population is given in Table II, are Peñon de Velez, Alhucemas, and Melilla (besides Ceuta).

Agriculture.—Agriculture is by far the most important Spanish industry, nearly 73 per cent. of those whose occupations were classified at the census of 1877 being entered under that head. In general it is in a backward condition, and is now much less productive than in the time of the Romans and again under the Moors. The expulsion of the latter people in many places inflicted upon agriculture a blow from which it has not recovered to this day. Aragon and Estremadura, the two most thinly peopled of all the old provinces, and the eastern half of Andalusia (above Seville),

² In all these cases the figures for Spain are the means of the years 1865-70 and 1880-83 inclusive.

have all suffered particularly in this manner, later occupiers never having been able to rival the Moors in overcoming the sterility of nature, as in Aragon, or in taking advantage of its fertility, as in Andalusia and the Tierra de Barros. The implements in general use are of the rudest description. The plough is merely a pointed stick shod with iron, crossed by another stick which serves as a share, scratching the ground to the depth of a few inches. But the regular import now of agricultural implements (chiefly from England and France) betokens an improvement in this respect. In general there has been considerable improvement in the condition of agriculture since the introduction of railways, and in every province there is a royal commissioner entrusted with the duty of supervising and encouraging this branch of industry. Among other institutions for the promotion of agriculture the royal central school at Aranjuez, to which is attached a model farm, is of special importance.

The provinces in which agriculture is most advanced are those of Valencia and Catalonia, in both of which the river valleys are thickly seamed with irrigation canals and the hill slopes carefully terraced for cultivation. In neither province is the soil naturally fertile, and nothing but the untiring industry of the inhabitants, favoured in the one case by the rivers which traverse the province from the tableland of New Castile and the numerous small streams (*nacimientos*) that issue from the base of the limestone mountains of which the province is largely composed, and in the other case by the numerous torrents from the Pyrenees, has converted them into two of the most productive regions in Spain. In the Basque Provinces and in Galicia the cultivable area is quite as fully utilized, but in these the difficulties that have to be contended with are not so great. The least productive tracts, apart from Aragon and Estremadura, are situated in the south and east of New Castile, in Murcia, and in Lower Andalusia—the marshes or *marismas* of the lower Guadalquivir and the *arcas gordas* between that river and the Rio Tinto. By far the greater part of the tableland, however, is any thing but fertile, the principal exceptions being the Tierra de Campos, said to be the chief corn growing district in Spain, occupying the greater part of Palencia in the north west of Old Castile, and the Tierra de Barros, in the portion of Badajoz lying to the south of the Guadiana in Estremadura, another district noted for its corn.

Except in Leon and the provinces bordering on the Bay of Biscay and the Atlantic irrigation is almost everywhere necessary for cultivation, at least in the case of certain crops. Almost all kinds of vegetables and garden fruits, oranges, rice, hemp, and other products are generally grown solely or mainly on irrigated land, whereas most kinds of grain, vines, and olives are cultivated chiefly on dry soil. The water used for irrigation is sometimes derived from springs and rivers in mountain valleys, whence it is conveyed by long canals (*acequias*) along the mountain sides and sometimes by lofty aqueducts to the fields on which it is to be used. Sometimes the water of entire rivers or vast artificial reservoirs (*puñtanos*) is used in feeding a dense network of canals distributed over plains many square miles in extent. Such plains in Valencia and Murcia are known by the Spanish name of *huertas* (gardens), in Andalusia by the Arabic name of *regas*, which has the same meaning. Many of the old irrigation works,—such, for example, as those of the plain of Tarragona,—date from the time of the Romans, and many others from the Moorish period, while new ones are still being laid out at the present day. Where no running water is available for irrigation, water is often obtained from wells by means of water-wheels (*norias*) of simple construction. In most cases such wheels merely have earthenware pitchers attached to their circumference by means of raps of asparto, and are turned by a horse harnessed to a long arm fitted to a revolving shaft. In recent years many artesian wells have been sunk for irrigation. According to Higgin (see Bibliography), the total area of irrigated land in Spain amounts to 4430 square miles. The effect of irrigation is shown by the fact that the irrigated portion of Murcia has a population of 1681 to the square mile as against 101 for the whole province, and Orihuela a population of 767 to the square mile as against 194 for the whole province of Alicante to which it belongs.

Cereals.

Cereals constitute the principal object of cultivation, and among these wheat ranks first, the next in importance being barley, the chief fodder of horses and mules. Both of these grains are cultivated in all parts—on the plains as well as among the mountains, but chiefly on the more level parts of the two Castiles and Leon, and on the plains of the basin of the Guadalquivir. Oats and rye are cultivated only in the higher parts of the mountains, the former as a substitute for barley in feeding horses and mules, the latter as a breadstuff. Maize also is cultivated in all the provinces, nevertheless the total extent of its cultivation is limited, since, being a summer crop, it requires irrigation except in the Atlantic provinces, and other products generally yield a more profitable return where irrigation is pursued. Rice is cultivated on a large scale only in Valencia. Among cereals of less importance are buckwheat (in the mountainous regions of the

north), millets, including both the common millet (*Panicum mitaceum*) and the so-called Indian millet (*Sorghum vulgare*, the *jodro* of India, the *durrah* of Africa), and even (in La Mancha) guinea corn (*Pennisetum spicata*). As to the quantity of cereals produced in the country we are without official information, and the estimates of the average annual production of cereals of all kinds are very discrepant, varying from 250 to 430 million bushels. The average production of wheat alone has been estimated¹ at 177 million bushels, and the average produce of that crop per acre at 11.13 bushels (that of England being about 29 bushels). If these figures can be taken as approximately correct, it follows that the average acreage under wheat in Spain is nearly 16 million acres, or between five and six times the average in Great Britain, which has less than half the area of Spain. The produce per acre just indicated places Spain among those countries of Europe in which the return is least, which is probably fully accounted for by the backward state of cultivation generally, and in particular by the small expenditure on manure. As a rule, in fact, the straw left on the ground is the only manure which the land receives.

The cereal and especially the wheat production of the country regularly furnishes a considerable export. During the five years 1879–83 the value of the export of cereals and pod fruits of all kinds was nearly 3 per cent. of the total value of the exports, but this export is balanced by a large import, especially of wheat flour. In bad years, indeed, the value of the import under this head greatly exceeds that of the export.

In the production of pod fruits and kitchen vegetables Spain is ahead of all other countries in Europe. The chick pea forms part of the daily food of all classes of the inhabitants, and among other pod fruits largely cultivated are various kinds of beans and peas, lentils (*Ervum lens*), Spanish lentils (*Lathyrus sativus*) and other species of *Lathyrus*, lupines, &c. The principal fodder crops are lucerne (*Medicago sativa*) and esparcetto (a variety of sainfoin). Clover, particularly crimson clover (*Trifolium incarnatum*), is grown in the northern provinces. Among vegetables garlic and onions take the chief place, and form an indispensable part of the diet of all Spaniards, besides these, tomatoes and Spanish pepper are the principal garden crops. It is upon such crops that the Spanish peasant in general bestows his chief care.

As regards the quantity of the product wine comes next after wine. cereals among the objects of cultivation in Spain. Here again we are dependent only upon vague estimates of the average amount produced, but usually the average annual Spanish production of wine is estimated at between 440 and 500 million gallons, an estimate which places Spain third (next after France and Italy) among the wine producing countries of Europe. So far as quantity is concerned the principal wine producing districts are in the north-east, but the only wines of Spain which have a world wide reputation are those of the south, and more particularly those which take the name of “sherry,” from the town of Jerez, in the neighbourhood of which they are grown. The total area under the vine is estimated at about 3,480,000 acres (or about 2.8 per cent. of the entire surface), and of this total about 772,700 acres belong to the Catalonian provinces, chiefly Barcelona. The provinces which produce most wine are Barcelona, Saragossa, Cadiz, and Malaga, the annual amount of the production being in the order in which the provinces are mentioned.

The official tables distinguish the wines exported from Spain as common wines, sherry and similar wines, and other full bodied wines (*vino generoso*). The returns of recent years, as will be seen from Table III given below, show that of late an enormous increase has taken place in this export both as regards quantity and value, this increase being chiefly due to the extension of the export of the commoner wines to France by way of Barcelona.

	Average of Five Years 1874–78		Average of Five Years 1879–83		1884	
	Thousands of Gallons exported.	Value in thousands of Pounds	Thousands of Gallons exported.	Value in thousands of Pounds.	Thousands of Gallons exported.	Value in thousands of Pounds.
Common wine..	40,524	2,547	137,562	7,748	134,432	8,865
Sherry and similar wines	6,440	2,460	7,874	2,137	7,668	1,464
Other full bodied wines	2,241	470	3,388	870	2,490	403
Total	49,214	5,483	148,824	10,764	144,590	10,803

There is also a large export of grapes and raisins, especially from the southern provinces (Malaga and Almeria). The average quantity of the two together exported in each of the five years

¹ In an article by M. P. A. Delboy in the *Journal of the Statistical Society for March 1884*, translated from the *Journal de la Société de Statistique de Paris*, September 1883.

1879-83 was about 50 millions of kilogrammes (110 million lb), the average value about £1,560,000. The vines whose fruit is intended for table use as grapes or raisins are trained on espaliers or on trees, especially the nettle tree (*Celtis australis*).

Fruits

Among fruit trees the first place belongs to the olive, which is estimated to cover about 3 per cent. of the surface, and accordingly about an equal area to that occupied by the vine. Its range in Spain embraces the whole of the southern half of the tableland, the greater part of the Ebro valley, and a small strip on the west coast of Galicia. Along the base of the Sierra Morena from Andújar to the vicinity of Cordova there run regular forests of olives, embracing hundreds of square miles. The annual production of oil is estimated at 55 millions of gallons, and might be greatly increased in quantity and improved in quality if more attention were bestowed upon the cultivation of the trees and the preparation of the oil. Oranges excluded from the plateau by the severity of the winter cold, are grown in great quantity on the plains of Andalusia and all round the Mediterranean coast, and figs, almonds, pomegranates, carobs, and other southern fruits are also grown abundantly in all the warmer parts, the first two even in central Spain and the more sheltered parts of the northern maritime provinces. In these last, however, the prevailing fruit trees are those of central Europe, and above all the apple, which is very extensively cultivated in Asturias, the Basque Provinces, and Navarre. The date palm is very general in the south eastern half of the kingdom, but is cultivated for its fruit only in the province of Alicante, in which lies the celebrated date grove of Elche. In the southern provinces flourish also various subtropical exotics, such as the banana, the West Indian cherimoya, and the prickly pear or Indian fig (*Opuntia vulgaris*), the last frequently grown as a hedge plant, as in other Mediterranean countries, and extending even to the southern part of the tableland. It is especially abundant on the Balearic Islands. The agave or American aloe is cultivated in a similar manner throughout Andalusia. Cotton is now cultivated only here and there in the south, but, on the other hand, sugar cane, the cultivation of which was introduced by the Arabs in the 12th century or later, and was of great importance in the kingdom of Granada at the time of the expulsion of the Moors at the close of the 15th century, but has since undergone great vicissitudes, first in consequence of the introduction of the cane into America, and afterwards because of the great development of beet sugar in central Europe, is now becoming every year more and more of a staple in the provinces of Granada, Málaga, and Almería. The annual production on the Spanish mainland is estimated at about 75,000,000 lb. Such prosperity as this branch of agriculture at present enjoys is largely due to the protection which it receives at the hands of the Spanish Government. A duty imposed on all imported sugars in 1876, while inflicting a severe blow on the Spanish colony of Cuba, has had the desired effect of stimulating the native production, but according to the law at present in force (passed on June 30, 1882) the amount of this duty, as far as regards the produce of the Spanish colonies, is being gradually reduced, and the duty will be entirely abolished on July 1, 1892.

Sugar

Among the vegetable products not yet mentioned the most important are the mulberry, grown in almost all provinces, but principally in those bordering on the Mediterranean, and above all in Valencia, the chief seat of the Spanish silk production and manufacture, hemp and flax, grown chiefly in Galicia and other northern provinces, among dye plants, madder, saffron, woad (*Isatis tinctoria*), and wild woad or dyer's weed (*Rhus tinctoria*), ground nuts (*Arachis hypogaea*), grown for their oil, for the preparation of which the nuts are exported in considerable quantity to France, liquorice, camellia, colocynth, &c.

Live stock.

The rearing of animals has likewise been receiving in recent years increased attention at the hands of both Government and people, though here also we are without recent official statistics to show the consequent advance. The middle of the present century appears to have been the time when this industry was at its lowest point, and the following table (IV) shows the increase in numbers that has taken place at certain subsequent dates for which official returns or estimates are obtainable—

	18,3	Enumeration Sep. 24 1865	Estimate 1878.
Horses	298,722	672,559	700,000
Mules	499,172	1,001,878	1,200,000
Asses	496,516	1,230,814	1,300,000
Cattle	1,557,033	2,904,598	3,000,000
Sheep	26,443,950	22,054,967	23,000,000
Goats	3,034,701	4,429,576	4,500,000
Swine	1,272,978	4,264,817	4,500,000
Camels		3,104	

In 1865 horses were reared chiefly in the provinces of Seville, Coruña, and Cadiz, mules in Toledo, Cuenca, Teruel, Saragossa,

and Badajoz, asses in Badajoz, Toledo, Murcia, Seville, and Granada, cattle in Oviedo, Coruña, Leon, and Pontevedra, sheep in Badajoz, Leon, Teruel, Soria, and Saragossa, goats in Cáceres and Badajoz, camels mainly on the Canary Islands, the total number on the Spanish mainland at the date of the enumeration being less than a hundred. Badajoz was the richest of the provinces in live stock of all kinds, containing about one fourteenth of the total number of domestic animals in the kingdom.

The only animals belonging to Spain still noted for their excellence are mules and asses, which are recognized as the best to be found anywhere. The quality of the horses has been greatly improved, however, since the establishment of Government studs more than forty years ago. Besides the cattle reared throughout the kingdom for field labour and (in the northern provinces) for regular dairy farming, hulls for the great national pastime of bull-fighting are especially reared in many parts of the country, particularly in the forests of Navarre, the mountains separating the two Castiles, the Sierra Morena, and the Serranía de Ronda in Granada, and also in separate enclosures on the islands of the Gualdquivir. Spanish sheep, which in former times enjoyed so high a reputation and formed so important a part of the national wealth, are far from having the same relative importance at the present day, though sheep-rearing also is sharing in the general rise of agricultural and other industries. The most famous breeds of Spanish sheep are the merinos or migrating sheep, which once brought immense revenues to the state as well as to the large proprietors to whom they mostly belonged. These sheep, which are distinguished by their long slim legs and still more by their long wool, are pastured in different districts in summer and winter. Their winter quarters are in the lower parts of Leon and Estremadura, La Mancha, and the lowlands of Andalusia, their summer quarters the more mountainous districts to the east and north (Plasencia in the province of Cáceres, Avila, Segovia, Cuenca, Valencia), which are not so much affected by the summer droughts of the Peninsula. The mode of the migration and the routes to be followed are prescribed by law. Each herd consists of about 10,000 individuals, under the command of a *mayoral*, and is divided into sections containing about 1000 each, each section under the charge of an overseer (*capataz*), who is assisted by a number of shepherds (*pastores*) attended by dogs. The shepherds, rudely clad in a sleeveless sheepskin jacket, the wool outside, and leather breeches, and loosely wrapped in a woollen mantle or blanket, are one of the most striking and characteristic objects in a Spanish landscape, especially on the tableland. The migration to the summer quarters takes place at the beginning of April, the return at the end of September. At one time the owners of merino herds enjoyed the right of pasturing their herds during their migrations on a strip of ground about 100 yards in breadth bordering the routes along which the migrations took place, a strip which had accordingly to be left uncultivated, but this right (the *mesa*, as it was called) was abolished in 1836 as prejudicial to cultivation. Since that date the migrating sheep have been compelled to keep the roads. The average quantity of wool exported in the five years 1879-83 was about 9,000,000 lb. Even in the best of the years (1883-84) the total export of Spanish wool to all countries was only about one thirtieth of the total average import of that commodity into the United Kingdom during the corresponding period.

Bees are reared chiefly on the cistus heaths and the districts abounding in *tomillares* (see p 297). The rearing of the silkworm on the mulberry trees of the Mediterranean provinces has already been referred to, the total annual production of raw silk in Valencia is estimated at 1,500,000 lb, in Murcia at 500,000 lb, and in Catalonia at 200,000 lb. The rearing of the cochineal insect, which was introduced into southern Spain in 1820, is being carried on with more and more success, especially round Málaga, Vélez Málaga, and Motril.

Fisheries.—The catching of tunnies, sardines, anchovies, and salmon on the coasts employs large numbers of fishermen, and the salting, smoking, and packing of the first three give employment to many others. Spanish fishermen likewise dive for coral on the coasts of Andalusia and the north of Africa. The fishermen of Catalonia and Valencia have the greatest reputation for their skill. The centre of the principal tunny fisheries of Spain is a small rocky islet called Cristina about three leagues from the mouth of the Guadiana. The fishing lasts from May to August, that of sardines from August to the end of January. The average value of the export of fish in 1879-83 was nearly £120,000.

Minerals.—The mineral resources of Spain are vast and varied, but are as yet far from being adequately turned to account. No European country produces so great a variety of minerals in large amount, and in the production of copper ore, lead ore, and quick silver Spain heads the list. In the production of salt and silver it is excelled only by Austria-Hungary, and, as regards silver, not always even by it. The following table (V) gives particulars regarding the production of some of the principal minerals in the years named—

	1863	1883				
		Thousands of Metric Tons produced	Value in thousands of Pounds at the Mine	Persons employed		
				Men	Women	Children
Iron ore	223	4,576	506 1	12 1,7	473	2,550
Lead ore	270	280	1,400 2	14,874	110	2,533
Argentiferous lead ore	40	25	167 5	3,578	72	102
Silver ore		23	88 3	539	2	14
Copper ore	246	2,465	1,094 5	9 710	681	1,265
Mercury	169	27	209 1	2,001	1	309
Zinc	481	51	50 4	1,572	111	297
Common salt		20 ^a	17 4	371	94	108
Coal ..		1,044	463 6	7,230	680	1,305

Of the minerals mentioned in the preceding table it will be seen that iron and copper ores are those which show the greatest advance as compared with 1863. The production of these two ores advanced with rapid strides during the ten years 1874-1883. In the former year the production of both stood at about 500,000 tons. The iron ore is chiefly obtained in Vizcaya and Mureia, the former yielding by far the greatest quantity (in 1883 four-fifths of the total production of Spain), but the latter yielding the best quality (average value of Mureian iron in 1883, 5 pesetas=4s. per ton at the mine, as against 2 25 pesetas, or 1s. 9½d, the average for the Vizayan ore). All except a small fraction of the copper ore is obtained from the province of Huelva, in which lie the well known mines of Rio Tinto. The lead ore is obtained chiefly in Murcia and Jaen. The famous mines of Linares belong to the latter province. Argentiferous lead is chiefly produced in Almorá, which also produces most of the silver ore of other kinds except argentiferous copper ore, which is entirely obtained from Ciudad Real. The still more celebrated cinnabar (mercury) mines of Almaden, the richest in the world till the discovery of the Californian mines of New Almaden, belong to Ciudad Real, and this province, together with that of Oviedo, furnishes the whole of the Spanish production of this mineral. Spanish salt is partly marine, partly derived from brine springs and partly from rock salt, of which last there is an entire mountain at Cardona in Barcelona. Coal is chiefly obtained in Oviedo, Palencia, and Cordova. The production is quite insignificant compared with the extent of the coal bearing beds, which are estimated to cover an area of about 3500 square miles, of which nearly a third belongs to Oviedo, between one eighth and one seventh to Burgos and Soria, and about one tenth to Teruel and Cordova. Among the less important Spanish minerals are manganese (chiefly in Ciudad Real), antimony, gold, cobalt, sodic sulphate, sulphate of barium (barites), phosphoric (a valuable manure, a variety of apatite found in Cáceres), alum, sulphur, kaolin, lignite, asphalt, besides a variety of building and ornamental stones.

The total number of mines (including springs for the production of mineral waters) in operation in Spain in 1883 was 2620, and the total number of labourers employed in them in that year was 57,026. The working of the mines is carried on under state supervision. For this purpose the whole kingdom, including the Balearic and Canary Islands, is divided into three sections, and each of these into four districts. Each section is under the charge of an inspector general of the first class, and each of the districts under an inspector of the second class. By the law of July 6, 1859, a large number of important mines, including all the salt works and rock salt mines, were reserved as state property, but financial necessities have compelled the Government to surrender one mine after another, so that at present the state possesses only the cinnabar mines and some salt works. Many of the mines have been granted to foreign (principally English) companies.

Of the metallic ores produced in Spain, those of lead and mercury are the only ones which are chiefly reduced in the country. Though the working of iron is an industry of old standing in Spain, and a primitive kind of forge takes its name from Catalonia (see Iron), the total production of iron, refined and unrefined, in Spain in 1883 was only 200,000 tons, and by far the greater part of the Spanish ore is exported, as will be seen by comparing Tables V and VI. The production of iron in Spain is, however, rapidly and steadily increasing, the total amount in the first year of the decade ending in 1883 having been less than 60,000 tons. During the same decade the amount of copper produced in the kingdom increased from about 5000 to 32,000 tons. The amount of steel produced in the kingdom is quite insignificant (little more than 400 tons in 1883). The following table (VI) gives particulars regarding the export of the chief mineral products of Spain in 1883—

¹ A metric ton=1000 kilogrammes=2205 lbs., or 3½ lbs. less than a ton avoirdupois.
² Exclusive of 100,000 tons produced in the state salt works of Torrevelilla (Alcañal).

Minerals	To United Kingdom	To France	Total export to all Countries
	Metric Tons	Metric Tons	Metric Tons
Iron ore	2,895,000	611,000	4,220,000 ¹
Argentiferous galena.	2,400	2,000	13,000

Copper, brass, and bronze in plates, tubes, and other forms	171,403	187,841	385,501

Manufactures—At the census of 1877 only about 3 per cent. of the population was returned as engaged in manufacturing industries. The principal manufacture is that of cotton, and the following table, which shows the position of Spain relatively to the other countries of Europe with reference to this branch of manufacturing industry, will also serve to some extent as an index of the rank belonging to Spain in mechanical industries generally—

TABLE VII—Average Import of Raw Cotton for Home Consumption in the Principal Countries of Europe during 1870-1883

	Millions of lb.		Millions of lb.
United Kingdom	1460 8	Spain	100 3
Germany	336 9	Holland	94 8
France	309 6	Belgium	54 7
Russia.	242 6	Switzerland	53 8
Austria Hungary	176 6	Sweden	21 6
Italy	116 0		

The average import per head of population during the same period was as follows—United Kingdom, 41 7 lb., Holland, 23 6, Switzerland, 18 7, Belgium, 9 9, France, 8 2, Germany, 8 2, Spain, 6 0, Austria Hungary, 4 6, Sweden, 4 6, Italy, 4 0, Russia, 2 9. It thus appears that Spain occupies the seventh place in the consumption of raw cotton, both in absolute amount and relatively to population. In the five years 1874-78 the average import of raw cotton into Spain was 79,690,000 lb., so that the increase of the average in the succeeding period of five years amounted to 25 8 per cent. Nevertheless the products of this branch of industry in the country do not yet suffice to meet the wants of the population. There is every year a considerable import of cotton manufactures, while the export of this commodity is too trifling to be included in the list of chief exports. The maritime provinces, being those most favourably situated for the import of coal, and, where necessary, of raw material, are the chief seats of Spanish manufactures, and the cotton industry is principally centred in Catalonia and, above all, in Barcelona and the surrounding district. This region is indeed the only distinctively manufacturing portion of Spain, and in it also the manufactures of linen and woollen goods and of lace are mainly carried on. Flax spinning and the manufacture of linen goods are pursued to a considerable extent in Galicia and Asturias. The silk industry, which is likewise of high importance, but inadequate to meet the home demand for silk fabrics, is chiefly centred in Valencia, next to which come Murcia and Seville. Metal industries are chiefly carried on in the Basque Provinces, where various articles in iron and copper are made. A royal factory for the making of artillery and other weapons of war exists at La Trubia, in Asturias. Toledo is still noted, as it has been from the earliest times, for the excellence of its sword blades. The manufacture of leather, another Spanish industry of old renown, is still extensively carried on in Catalonia and elsewhere, but the making of *cordovan* has long ceased to be a specialty of Cordova, from which it takes its name. Boots and shoes and other articles in leather form the only considerable export of manufactured goods. Gloves are made in great quantity in Madrid, shoes in the Balearic Islands. The paper industry is very flourishing, especially in Catalonia and Valencia. Esparto is twisted into cords and ropes, and plaited into a variety of other articles, in Murcia and Alicante and elsewhere. The refining of cane sugar is largely carried on in Barcelona, Malaga, Almeria, and Granada, and

³ Of this total 478,000 tons were exported to Holland 142,000 to Belgium, and 109,000 to the United States.

⁴ All the blende and one-third of the calamine were exported to Belgium.

⁵ Chiefly to Portugal.

⁶ Of this total 158,760 lbs. were exported to Belgium.

⁷ Chiefly to Cuba.

the making of olive oil and brandy is general. So also is the making of charcoal, which in most parts of Spain takes the place of coal for all ordinary heating purposes, and even in some cases in mechanical industries. The large furnaces for the distillation of mercury at Almaden were at one time, if they are not still, heated solely with charcoal obtained from the *Cistus ladaniferus*. Among manufacturing industries of less importance are the making of porcelain (at the royal factory of Moncloa, near Madrid), glass and earthenware, soap, chocolate, and cork stoppers. The manufacture of tobacco, which is a royal monopoly, is carried on at seven factories—at Seville, Madrid, Santander, Gijón, Coruña, Valencia, and Alicante, —that of Seville being the largest.

Foreign Commerce—Possessing such varied resources as it does, and being peculiarly favourably situated for commerce, Spain might be expected to take a leading place among the trading communities of Europe. This it did at one time hold, when the treasure acquired by the discovery of America and the conquest of Mexico and Peru was squandered in the purchase of various commodities from England, the Netherlands, and other countries. This period of outward prosperity, however, was also that in which the seeds of decline were planted. The expulsion of the Moors from Granada was contemporaneous with the discovery of the New World. Hundreds of thousands of Moors were driven out from the country on subsequent occasions, and in the act Spain lost the best of her agriculturists and handicraftsmen. For the stay-at-home industry by which the resources of the land could be developed as they had been by the Moors the Spaniards of that day had no taste. Excited by the hope of rapidly acquired wealth and the love of adventure, the more enterprising spirits embarked upon a career of discovery, and agriculture and manufacturing industry fell into contempt. The mercantile supremacy of the country was thus short-lived. Political causes superadded to hasten the country's decline, and it is only within recent times, since the introduction of railways, that the commerce of the country has begun to revive. The average value of the imports and exports combined during the period of ten years from 1875 to 1884 was equal to rather less than £2 per head, against about £18 per head during the same period in the United Kingdom, but even this state of matters shows a considerable advance compared with 1859, when the total value of the exports and imports was equal to only about £1, 12s per head. The following table (VIII) gives total value in round numbers of imports and exports, with percentages from and to Great Britain and France, at various dates from 1849 (the year after the opening of the first railway in Spain) to 1884—

Years	Value of Imports.	P c. from Britain	P c. from France	Value of Exports	P c. to Britain	P c. to France
1849	£6,260,000			£5,210,000		
1860	14,833,000	25	20	10,982,000	29	22
1865	16,262,000	26	34	12,864,000	29	27
1870	20,877,000	24	39	15,982,000	29	36
1875	22,812,000	34	26	18,081,000	34	16
1880	28,482,000	18	39	20,929,000	32	30
1881	26,023,000	21	32	20,836,000	33	33
1882	32,607,000	21	27	30,716,000	31	41
1883	35,735,000	21	26	28,779,000	28	42
1884	31,166,000	21	25	24,768,000	27	43

On the average of the five years 1879–83 the principal exports, in the order of their importance, were wine, metals and mineral ores, fruit, oil, and cork,—wine being by far the most valuable, the principal imports, in the order of their importance, raw cotton, brandy and spirits, sugar, machinery, tobacco, coal and coke, timber, cod fish, iron (wrought and unwrought), hides and skins, chemical products, cocoa, cotton manufactures, and mineral oils. The large imports of cod fish (from Norway and British North America) are due to the large consumption of fish, especially during Lent, the great demand for mineral oil as a source of light is a consequence of the dearth of coal. It is interesting to note the high place which cocoa takes among the imports. The average import of that commodity is nearly double that of coffee, and that of tea is quite insignificant (in 1884 only 155,777 lbs.)

The foreign commerce of Spain is chiefly carried on with the United Kingdom, France, Cuba, and the United States. In the ten years 1873–82 France, the United Kingdom, and the United States together (in the order named) furnished on an average rather more than 67 per cent. of the imports, and the United Kingdom, France, and Cuba (also in the order named) received on an average during the same period 75 per cent. of the exports. Next to the three countries mentioned, those which had the largest share in the import trade during the same period were Cuba, Portugal, and the Argentine Confederation, and in the export trade Portugal, the United States, and the Argentine Confederation. From the United Kingdom Spain received in 1884 chiefly coal and coke, iron and articles in iron (articles in wrought-iron and steel, however, in rather greater amount from Belgium), locomotives

(also from Belgium), jute and jute yarn, hemp and flax yarn, sulphur (for use in the vineyards), and alkaline carbonates, from France, chiefly wool and woollen goods, silk and silk goods, and wheat flour, from the United States, petroleum, raw cotton, and tobacco (also from the Philippine Islands), from Cuba chiefly sugar and fine woods, from the Argentine Confederation chiefly untanned hides and skins and animal fats. Wheat was received chiefly from Russia, and spirits from Germany, which also supplied a large proportion of the sugar consumed in the country.

Of the principal export of Spain—wine—by far the greater proportion goes to France. In 1884 that country received four fifths of the common wine, and the quantity is rapidly increasing. The wine classed as full-bodied also went chiefly to France, but that entered under the head of sherry and similar wines was imported chiefly by the United Kingdom. The destination of the minerals is shown above (Table VI). Oranges were sent mainly to the United Kingdom, France, the United States, and Germany, raisins chiefly to the United States and the United Kingdom, olive oil chiefly to Cuba, Denmark, and France, but in considerable quantity also to other countries, esparto grass almost entirely to England, cork and wool chiefly to Portugal and France, cattle chiefly to Portugal and England, raw silk mainly to France, and wheat flour and chick-pease chiefly to the Spanish West Indies.

The foreign trade of the country is of course carried on mainly by sea. In 1884 more than 80 per cent. both of the imports and exports were transmarine, and of the land commerce by far the largest proportion is with or through France. The smallness of the trade with Portugal, which on an average furnished less than 1½ per cent. of the imports and received less than 5½ per cent. of the exports during 1873–82, is partly due no doubt to the similarity of the chief products of the two countries, but also to the defectiveness of the communications between the two countries, a circumstance largely accounted for by the physical conditions already alluded to. The introduction of railways has as yet only partially served to bring the countries into more intimate relations. On the first of January 1885 not a single line connected with the general system of Spanish railways entered Portugal north of the Tagus, though Lisbon was connected by rail both with Madrid by way of Cáceres and with Valencia by way of Ciudad Real and Albacete. At the date mentioned, however, a railway intended to connect Salamanca with the mouth of the Mondego was in course of construction, and a branch from the Portuguese coast line in the north was in process of being connected with the Spanish railway to Coruña, and by way of Leon with other northern seaports.

The foreign commerce of Spain is greatly hampered by the number and amount of the custom duties, which are imposed on all the principal articles both of export and import. On imports the duties vary from 6 to 28·33 per cent. of the value of the commodities, the highest duties being upon cotton yarn, sugar, and cocoa (to protect home or colonial industries). For protective reasons high import duties are levied also on iron manufactures, woollen manufactures, live animals, coffee, and wine. Export duties are levied mostly in proportion to quantity. In the case of sherry it amounts to 200 pesetas (£8) per hectolitre (22 gallons), full-bodied wines pay 112 pesetas per hectolitre, and ordinary wines 33 pesetas per hectolitre. In the case of "the most favoured" nations slight reductions are made in the amount of the duties, and under a treaty which came into operation on the 15th of August 1886 Great Britain enjoys the benefit of the most favoured nation treatment in consideration of a reduction in the import duties levied at British ports on Spanish wines.

Shipping and Navigation—Relatively to the extent of its coast-line and the number and excellence of its seaports (of which there are sixty on the Mediterranean coast, fifty-six on the Atlantic), the amount of shipping belonging to Spain is small. In 1884 the total register tonnage was 524,000 tons, not much more than that of Sweden at the same date, and only about half that of Italy. The number of vessels was 1803, including 301 steamers. Nearly half the transmarine imports (reckoned by value) and 68 per cent. of the transmarine exports were carried under a foreign flag. The following table (IX) gives further particulars as to the shipping of 1884—

Flag.	Metric Tons (in Thousands) of Cargo		Percentage of Total.	
	Discharged.	Loaded.	Imports.	Exports.

The total number of vessels entered with cargo under the national and foreign flags in 1884 was thus 11,122, and the total quantity of cargo discharged by them at Spanish ports 2,760,378 metric tons, the total number of vessels cleared with cargo 13,110, and the total quantity of cargo taken on board by them at Spanish ports 5,880,385 metric tons. Of the total number of vessels entered with cargo 6768 were steamers, which discharged 2,052,037 tons of cargo, and 4354 were sailing vessels, which discharged 707,411 tons of cargo. Of the number of vessels cleared with cargo 9506 were steamers, which took on board at Spanish ports 5,300,366 metric tons of cargo, and 3604 were sailing vessels, which took on board 580,019 metric tons of cargo.

Communication—The communications in Spain have been greatly improved since the beginning of the present century. In 1808 there were little more than 500 miles of carriage roads, but now there are over 28,000. At the end of 1882 14,600 miles were state roads, all well built and well maintained, and 3027 miles of state roads were in course of construction. The aggregate length of the provincial roads then completed was 2714 miles, and that of the communal roads 10,760 miles. In the mountainous districts, where there are only narrow paths, frequently rather steep, it is still not uncommon to meet long trains of mules.

Railways have made great advance since the middle of the century. The oldest line is that from Barcelona to Mataro, 17½ miles, which was opened on the 23rd of October 1848. Of late years railway construction has been going on pretty rapidly. In 1880 the number of miles open for traffic was 4645, and in the four succeeding years it was 4800, 4867, 5118, and 5386. All the Spanish railways belong to private companies, but most of them have obtained subsidies from the Government, to which most of the Spanish railways will revert at the end of a term of ninety-nine years. In granting a concession for a new railway the regular practice is to give it to whatever company offers to construct it with the lowest subsidy. The total amount of the subsidies for railway construction up to the end of 1884 was £25,676,600. For strategical reasons the Spanish gauge was made different from that of France.

The postal and telegraphic systems have been placed on the same footing as in other civilized countries. The total number of letters, post cards, and samples (including official and international letters, &c.) that passed through the post office in 1882-83 was 111 millions. The length of state telegraphic lines on January 1, 1883 was 10,664 miles, and of wires 25,989 miles. The number of messages in 1883 was 3,020,000, nearly 80,000 being transit messages and 654,000 from or to foreign countries.

Army and Navy—Military (or naval) service is obligatory on all Spaniards, but in certain cases recruits are allowed to buy themselves off. According to the law of January 8, 1882, the period of service for all arms is twelve years, of which three years must be passed with the colours, three years in the active reserve, and six years in the second reserve. The minister of war is empowered, however, on financial grounds to transfer troops serving with the colours to the active reserve before the period of three years' service has been fulfilled. Liability to service begins with the first day of the calendar year in which the twentieth year is completed. Persons holding a civil appointment or pursuing

any handicraft independently are allowed to buy themselves off for 1600 pesetas (£60), and brothers are allowed to take each others' place in service, or to exchange the numbers that have fallen to them by lot in the raising of the recruits for the year. For carrying out the law Spain is divided into fourteen military districts, the boundaries of which do not at all coincide with those of provinces.

The actual strength of the regular army is fixed at about 94,000 men for the kingdom (including the Balearic and Canary Islands), but this number may be brought up to 400,000 in time of war. The strength of the regular army in Cuba is about 22,500 men, in Porto Rico about 3200, and on the Philippine Islands about 8200. The active army is divided into 140 battalions, besides the same number of depot and reserve battalions, 24 cavalry regiments, and the same number of depot squadrons and reserve cavalry regiments, 9 regiments of field artillery, and 3 of mounted artillery, besides 6 reserve regiments of artillery, and 10 battalions of engineers. There are also 13 battalions of fortress artillery.

The following statement shows the strength of the navy in Navy 1885—*First Class*—4 ironclad frigates (55 guns), 4 screw frigates (97 guns), 6 cruisers (48 guns), *Second Class*—5 frigates (104 guns), 3 cruisers, 12 corvettes and troopships (39 guns), *Third Class*—1 ironclad monitor (3 guns), 1 floating battery, 79 gunboats, transports, &c. (124 guns).

There were at the same time building one ironclad of the first class, five cruisers of the second class, besides torpedo boats, tugs, and other vessels. For the defence of the colonies, and more particularly those of the West Indies, there are thirty-five screw gunboats, all of the same size (about 5 feet draught), and each carrying a 100 pounder pivot gun at the bow.

The navy is manned by conscription in the maritime districts. In 1885 the number of seamen was about 14,000, that of marines about 7000.

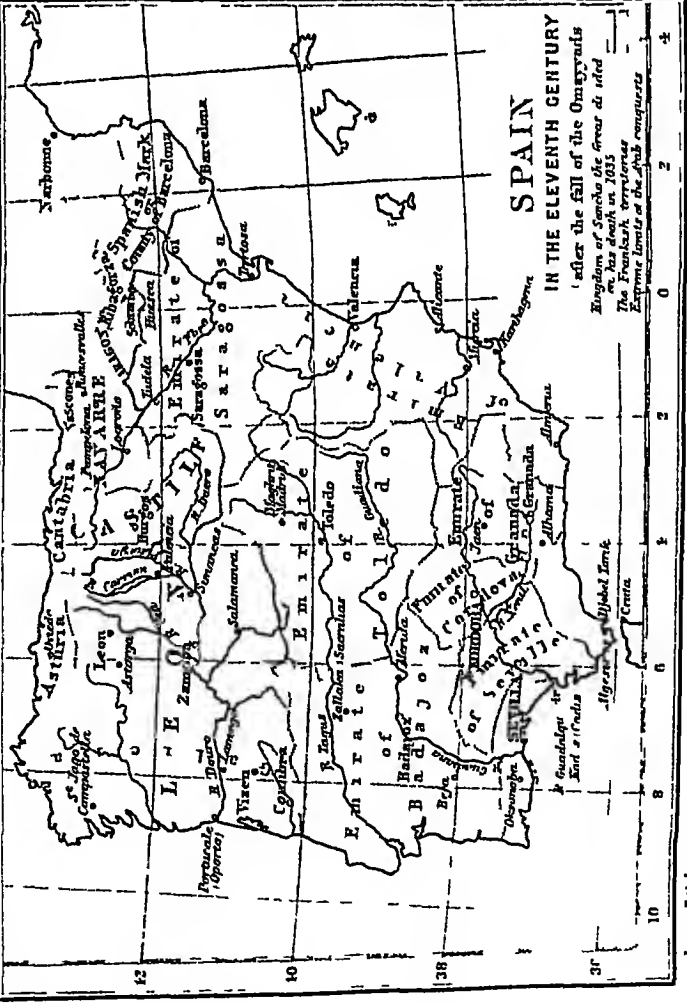

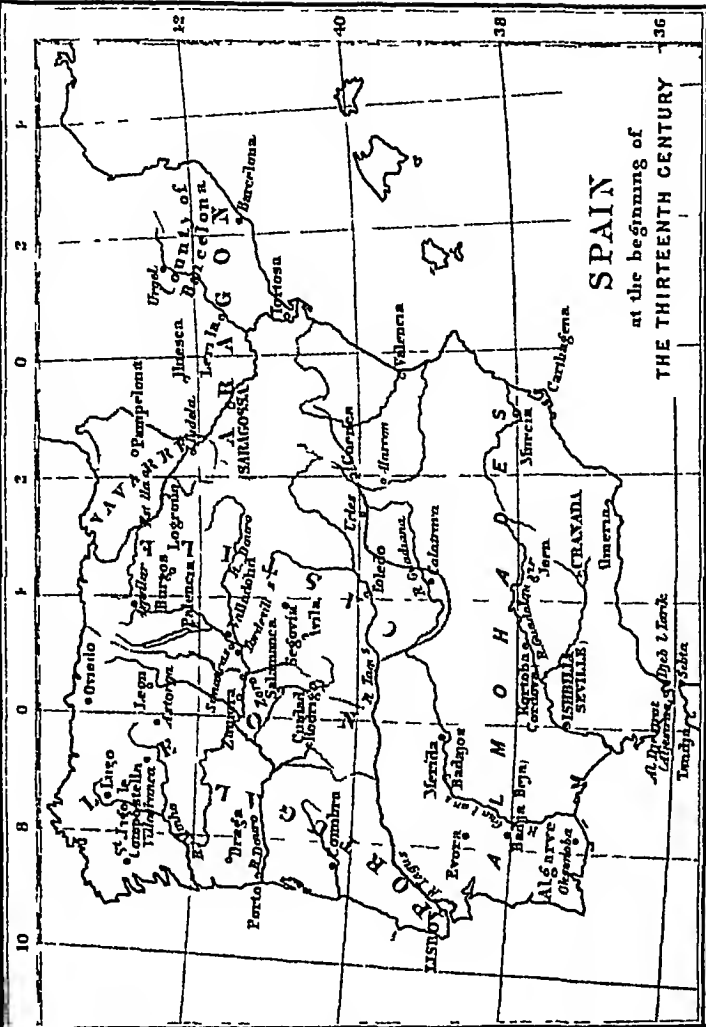

Religion—Roman Catholicism is the established religion, and Religion the church and clergy are maintained by the state. The immense majority of the people (in 1877 16,003,959 out of a total of 16,034,345) are professed adherents of this faith, so that, so far as numbers go, Spain is still the most "Catholic" country in the world, as it has long been styled. According to Willkomm, however, religious indifference is now very general, not only among the educated but also among the lower classes, and of the bigotry and fanaticism which in former times led to the destruction of hundreds of thousands of victims at the hands of the Inquisition the only traces at the present day are to be found, says the same authority, in the provinces of Aragon, Navarre, and Extremadura, where the clergy still exercise a considerable influence over the lower orders. By the constitution of 1876 non-Catholics are permitted to exercise their own forms of worship, but they must do so in private and without making any public announcement of their services. At the census of 1877 the total number of Protestants was 6061, a number below that of those entered as rationalists (9645). There are nine archbishoprics (Toledo, Madrid, Burgos, Granada, Santiago, Saragossa, Seville, Tarragona, Valencia, and Valladolid) and forty-five bishoprics. The archbishop of Toledo is primate.

Education—By the law of July 17, 1857, primary education was declared compulsory on all children of school age (originally fixed at six to nine) and made free to the poor, but the results of the census of 1877, though showing an advance in elementary education as compared with previous years, makes it clear that this law is far from being efficiently carried out. At that date the total number who could both read and write was 4,071,823, equal to 24.48 per cent of the population, as against 19.07 per cent in 1860. The provinces in which the percentage of those able to read and write was greatest were Alava, Burgos, Poncevedra, Madrid, Santander, those in which it was least were the Canary Islands, Granada, Malaga, Almeria, Alicante, Castellon.

There are ten universities—those of Madrid (founded in 1836 to replace the long celebrated university of Alcalá), Barcelona, Granada, Salamanca, Seville, Valencia, Santiago, Saragossa, Valladolid, and Oviedo, that of Madrid is now the most celebrated and the best attended, while that of Salamanca, so renowned in the Middle Ages, is now in least repute.

Political Administration—Spain is an hereditary monarchy, the constitution of which rests on the fundamental law of June 30, 1876. The sovereign becomes of age on completing his or her sixteenth year. The sovereign is grand master of the eight Spanish orders of knighthood, the principal of which is that of the Golden Fleece (Toison de Oro), founded in 1431 by Philip of Burgundy. The chain of this order surrounds the royal arms, in which are included, besides the arms of Castile, Leon, Granada, and the lilies of the royal house of Bourbon, the arms of Austria, Sicily, Savoy, Brabant, and others. The national colours are red and yellow. The flag is divided into three horizontal stripes—two red stripes, with a yellow one between bearing the royal arms.

The legislative authority is exercised by the sovereign in conjunction with the *cortes*, a body composed of two houses—a senate

barbarous Celts and Iberians, with some Phœnician settlements for the purposes of trade on its southern coasts. Several of these places were just known to them by name, but even of Gades, rich and populous as it seems to have been in quite early days, nothing but vague hearsay had reached them, and Herodotus, who mentions it as Gadeira (iv. 8), merely defines its position as "on the ocean outside of (beyond) the Pillars of Heracles." Tarraco, one of the oldest and most important of the cities of Spain, and one of which we hear continually in the subsequent history of the country, was also in all probability a Phœnician colony. There are still here remains of very ancient walls, possibly Phœnician work. Gades, Tartessus, Tarraco, all seem to have been of Phœnician origin¹ and of unknown antiquity, and they were flourishing places in the 7th century B.C., when the Greeks first made a slight acquaintance with them,—an acquaintance, however, which they did not follow up. The result is that we really know nothing about Spain till the first war between Rome and Carthage (264-241 B.C.). There was indeed, in the 4th century B.C., an embassy to Alexander the Great from the remote West, of Gauls and Iberians, and from that time learned Greeks began to discuss the geography of Spain. But again the country drops out of sight till the 3d century B.C., when we find a close connexion established between it and Carthage, which, being itself a Phœnician colony, would feel itself almost at home on the southern shores of Spain. According to Polybius, Carthage (before the First Punic War) had acquired at least something like a protectorate over the Iberian tribes as far as the Pyrenees, the then recognized boundary between the Iberians and Celts,—between, in fact, Spain and Gaul. Spanish troops served as volunteers in Carthaginian armies. There must have been a good deal of Phœnician blood in the south of Spain for many centuries, and this no doubt prepared the way for Carthaginian ascendancy in the country. Not, however, till after the First Punic War and the loss of Sicily was there anything that could be called a Carthaginian empire in Spain. It was in 237 B.C. that Hamilcar Barca, the father of Hannibal, crossed the Straits of Gibraltar and set foot in Spain, not, however, with any commission from the home Government at Carthage, but with the deliberately formed design of making the country, with its warlike population and great mineral wealth, into a Carthaginian province, and ultimately into a basis of operations in a future war with Rome (see HAMILCAR, HASDRUBAL, HANNIBAL). There were rich mines in the mountains, which had drawn the Phœnicians some way into the interior, and among the native tribes there were the elements of a brave and hardy soldiery. A good army might very well be organized and paid out of the resources of Spain. All this Hamilcar clearly saw, and in the true spirit of a statesman he set himself to the work, not merely of subjugating the country, but of making the Spaniards into loyal subjects of Carthage. He encouraged marriages between his officers and soldiers and the native women; his own son Hannibal married a Spanish woman. He showed them how to work their gold and silver mines to the best advantage, in every way, in short, he made them feel that he was their friend. The great work of which he had laid the foundation was carried on after his death in 228 by his son-in-law Hasdrubal, under whom New Carthage, with its fine harbour, founded probably by Hamilcar, became the capital of the country. It would seem that by this time the Carthaginian empire in Spain was as firmly established over the southern half of the country as the fickle and uncertain temper of the native tribes would admit. The

Spaniard of that day, as indeed more or less throughout his whole history, was particularly amenable to personal influence, and an Hamilcar or a Hannibal could sway him as he pleased. From 228 to 221 Hasdrubal was extending and strengthening the Carthaginian rule in Spain, while the Romans were fighting in Cisalpine Gaul. One precaution, indeed, they had taken, an understanding with Hasdrubal, which might be regarded as a treaty, that the Carthaginian conquests were not to be pushed east of the Ebro. West of that river there was one town, Saguntum, a Greek colony, in alliance with Rome, this Hasdrubal had spared. His successor, Hannibal, after two years' continuous fighting, which resulted in the submission of hitherto unconquered tribes and the undisputed supremacy of Carthage throughout almost all Spain, attacked and took the place in 218.

Thus was the beginning of the Second Punic War. Spain was now for the first time entered by Roman armies, under the command of the two Scipios,—the brothers Cneius and Publius. Six years of hard fighting ended in the defeat and death of these two brave men, but in 210 the son of Publius, the elder Africanus, struck a decisive blow at the Carthaginian power in Spain by the sudden capture of New Carthage. The war, however, still dragged on till 205, in which year it may be said that Spain, or at least that part of it which had been under Carthage, was fairly conquered by the arms of Rome. Andalusia, Granada, Murcia, Valencia, Catalonia, Aragon, may be said to have become Roman territory. Rome had now to deal simply with the native Spaniards, without the fear of any foreign interference. Hence from 205 the reduction of the country into a Roman province was only a matter of time. It proved, however, to be a tedious and troublesome work, and more than once Rome's hold on Spain was seriously imperilled. An oppressive governor, or a governor without tact and sympathy, was sure to unsettle the restless and impressionable tribes, and to stir up all manner of dangerous jealousies and heart-burnings. The Scipios, the elder Africanus especially, knew how to manage the people, and yet even in 205, the year of those brilliant successes of Africanus, there was a great rising of several of the tribes, headed by a local chieftain, against the dominion of Rome. It was quelled after a sharp engagement, there was a general submission on the part of the Spaniards, and many of them became Roman tributaries. It was some time, however, before the country, or even the southern half of it, was really subdued into complete peace and order. The mountains and the forests were a formidable obstacle to the Roman legions, and favoured that guerilla warfare which makes conquest slow and laborious. For a long period many of the tribes were rather the allies and dependants of Rome than her subjects, and might at any moment be roused into war. In fact, Rome's dominion west of the Ebro—Further Spain (*Hispania Ulterior*), as the province was called—must for very many years have been little more than nominal. Rome's policy was to keep the native tribes disunited, and to have as many of them as possible under a friendly protectorate. There seem to have been wide differences between these tribes,—some, especially those in the interior and in the north, being fierce and utterly barbarous, and others in the south and south-west comparatively mild and civilized. The Celtiberi, in the interior, were a group of warlike tribes, and were always uncertain and intractable. At one time they would fight for Rome, at another they would serve as mercenaries for Rome's bitter foe, the Carthaginian. Continually were they breaking out into revolt and defying the arms of Rome. The "Celtiberian War" often figures in the pages of Roman histories, and it generally meant a war

¹ For the Phœnician colonization of Spain, see PHœNICIA, vol. viii p. 806

involving the greater part of Spain. In 195 the elder Cato had to put down a rising in the country, in which the Celtiberi took the lead, but he offered them favourable terms, and showed himself particularly anxious to conciliate them. His Spanish campaigns were so far a success as to establish the Roman power east of the Ebro, and along with peace and order came better administration and a development of the resources of the district now known as Hither Spain (*Hispania Citerior*). Cato is said to have disarmed the inhabitants of this part of Spain, and to have even compelled the Spaniards, from the Pyrenees to the Guadalquivir, to pull down their fortifications, but still the smouldering fires of rebellion were not trampled out. Some few years afterwards, in 179 and 178, we find the father of the famous Gracchi governor of Hither Spain, and fighting with the troublesome Celtiberi, winning victories over them, capturing one hundred and three of their towns, and then securing his conquests by showing himself as great in peace as he had been in war. He seems to have anticipated in Spain the work attempted by his sons in Italy, making grants of land on favourable conditions to the poorer natives. Much must have been accomplished by Gracchus towards producing contentment with the Roman rule, but in the west, in the valleys of the Douro and the Tagus, and in the region known as Lusitania, answering to Portugal, there seems to have been almost incessant fighting, and what one general won another general often lost. Under Mummius, a governor of Further Spain (154),—the Mummius who in 146 took and sacked Corinth,—the Romans suffered a disastrous defeat from the Lusitanians, of which the Celtiberi took prompt advantage, and there was another Roman defeat, with a massacre of Roman citizens in one of the towns of the interior. These losses were avenged in 152 by Claudius Marcellus, grandson of Hannibal's illustrious antagonist, during whose command in Spain Corduba is said to have been established as a Roman colony. Marcellus was too humane and considerate to the Spaniards to suit the ideas of the Roman senate, which we may well suppose to have been greatly provoked by the trouble which Spain had given them. The new governors, Lucius Lucullus and Servius Galba, by a combination of perfidy and extortion, drove the country into a most formidable revolt, with which the Romans, whose hands were tied by the Third Punic War, could not for some time effectually deal. A guerilla chief of Lusitania (which had been specially ill-treated by the Romans), Viriathus, headed the revolt, and from 147 to 140 army after army of the Romans was cut to pieces, the formidable Celtiberi had joined his standard, and Spain seemed well nigh lost to Rome. A treaty was even extorted by Viriathus from one of the Roman commanders, declaring the independence of the Lusitanians, and it is said to have been acknowledged and accepted by the senate. The brave man, however, could not hold together his fickle Spanish levies, and he fell at last by native treachery, encouraged by or at least connived at by the Romans. The Celtiberi, however, were still in arms, the strong city of Numantia, the capital of the Arevaci, the most powerful Celtiberian tribe, witnessed more than once the defeat of a Roman consul before its walls (141 to 140). The besieging army became despondent and demoralized, and its commander, supplies failing him, had to retire, leaving his sick and wounded behind him. It was humiliation indeed for Rome to be thus baffled by a half-barbarous country-town of no great size, in the interior of Spain. She now sent her best general, the younger Scipio, into the country, and in 133 the capture and destruction of Numantia gave Rome a hold over the inland district of Spain which she had never before had (see Scipio). The province of Hither Spain was rendered safe from Celtiberian incursions. Shortly afterwards Lusitania and its towns, after some obstinate fighting, were reduced to submission by the consul Junius Brutus, and thus Spain, with the exception of its northern coasts, the home of its most barbarous tribes, was nominally Roman territory. There must have been by this time a considerable mixture of Roman blood with the native population, there were several towns—Carteia, Valentia, Tarraco especially among them—with a Latin municipal constitution and with a number of Latin-speaking people. The growth of Roman civilization had fairly begun, and it was promoted by a commission sent out by the senate after Scipio's victory. Peace in the Mediterranean was checked in the interest of native Spanish commerce, and the Roman administration generally favoured the development of the country's prosperity. The extensive mountain districts were still the shelter of banditti, but, on the whole, order was well maintained, and Spain from this time flourished under Roman rule. It abounded in flocks and herds, and had a number of thriving populous towns, particularly on its Mediterranean shores. It seems, too, that it was never oppressed and impoverished by some of those forms of tribute,—such as the exaction of a tenth of the produce,—under which many of Rome's provincials smarted. Fixed money payments, and military service in the Roman army, were the chief burdens which the conquered Spaniards had to bear. Rome on the whole, by comparison, dealt tenderly with them. Several of their towns had the privilege of coining the silver money of Rome, and the flourishing cities along the Mediterranean coast, which were so many centres of civilization to the adjacent districts, were treated rather as allies than as subject. In the east the Romanizing process went on rapidly and under favourable conditions, while the west and the north and a great portion of the interior remained barbarous, and Roman merely in name. In 105 it seemed possible that the Romans might be utterly swept out of the country, in that year a great wave of invasion passed over the inland regions from the Cimbri, who had destroyed two Roman consular armies on the Rhone. Spain to a great extent was cruelly ravaged, and Rome was too seriously menaced by the barbarians nearer home to be able to protect her. The country was saved by the brave Celtiberi, whose determined resistance forced the Cimbri back upon Gaul. Again in 97 and 96 we hear of a rising of these same Celtiberians against Rome, and of campaigns in the interior, in which for the first time we meet the name of the famous Sertorius, a name almost as conspicuous in Sertorius' ancient Spanish history as that of Hamilcar or Hannibal. For the remarkable episode of the eight years' wars of Sertorius in Spain against the generals of Sulla and against the great Pompey, and his almost successful attempt to render the country independent of the home Government at Rome, we must refer the reader to the article SERTORIUS. It was to his skill in winning the hearts of the Spaniards, more even than to his very considerable military ability, that he owed his success. Rome was financially most grievously embarrassed by this tedious and difficult war, and Spain, with its Roman civilization and its Latinized towns on the Mediterranean, suffered severely. By the year 71 the country had been reconquered by Pompey for Rome, and the two Pompey provinces of Hither and Further Spain were reorganized under a somewhat more stringent rule, the tribute in some districts of the latter province being raised, and some of the towns in both losing their municipal independence. In 61 the great Caesar was governor of Further Spain, and carried the arms of Rome into the

Spain
under
Roman
rule.

imperfectly conquered regions of the west and north west, the country of the Lusitanians and of the Gallaeci, and with a fleet from Gades is said to have occupied a point in the north-west answering to Coruña. But he was too short a time in Spain to reduce these barbarous regions to permanent subjection, and the work still remained to be accomplished. In the civil war with Pompey in 49 he was in Hither Spain, winning decisive victories over Pompey's generals, Afranius and Petreius. Once more, in 45, he had to enter further Spain at the head of an army, and to defeat his rivals sons at Munda, somewhere probably in the neighbourhood of Cordova, a victory which made him undisputed master of the Roman world. Spain, however, the northern part at least, was not thoroughly subdued—"pacified," in Roman phrase,—till the reign of Augustus, whose ambition it was to advance the boundaries of empire to the ocean. In the north was a wild and warlike highland population, a collection of tribes known as the Astures in the north-west, and their neighbours the Cantabri to the east, between a mountain range and the coast, "the last," as Gibben says (*Decline and Fall*, ch. 1), "to submit to the arms of Rome and the first to throw off the yoke of the Arabs." Caesar's flying visit in 61 had done something to cow these tribes, but ever and again they would assert their independence. In 27 the emperor Augustus himself penetrated their strongholds, and he passed two years in Spain, decisive victories were won over the northern tribes, and their towns and villages were converted into military posts in the occupation of the legionary veterans. Such was the origin of Saragossa, a modern survival of the name of Caesar Augusta then given to an old town on the Ebro, henceforth an important Roman centre in Spain. The successes of Augustus were commemorated by the same title bestowed on other ancient Spanish towns, Bracara Augusta (Braga) in the north-west, Asturica Augusta (Astorga) still further north, Emerita¹ Augusta (Merida) on the Guadiana, which became a Roman city of the first class,—“the Rome of Spain,” as it has been called,—and Pax Augusta, perhaps the modern Badajoz. The work of consolidating the Roman dominion in Spain was completed in 19 by his friend and minister, Marcus Agrippa, and now at last the “Cantaber non ante domabilis,” as Horace has it, acknowledged Rome's supremacy. Spain was fairly conquered, the warlike peoples of the north were cowed and broken, the south was thoroughly Romanized, the population having adopted Latin manners and the Latin tongue. Some of the best specimens of Roman architecture, some of the finest Roman coins, have been discovered in the cities of Spain, which from the time of Augustus became rapidly prosperous, and were famous for their schools and their scholars. Spain, in fact, was more completely Roman than any province beyond the limits of Italy. The country which had hitherto harassed Rome with incessant risings and insurrections was at last peaceful and contented, a happy land which for the next 400 years may be said to have had at least no military history.

Under Augustus the old political constitution into two provinces, Further and Hither Spain, of which the Ebro had been the boundary, was set aside, and exchanged for a division into the three provinces of Lusitania, Bætica, and Tarraconensis, sometimes spoken of as the “Three Spains.” Of these Bætica, so called from the Bætis (the Guadalquivir), and answering nearly to Andalusia inclusive of Granada, was the smallest, Tarraconensis, which embraced Hither Spain and the interior and all the north, was much the largest. Lusitania corresponds to modern

¹ Emerita, from “emeriti,” soldiers whose term of service had expired,—in fact, “veterans from the legions.”

Portugal. The centres of administration were—for Tarraconensis, Tarraco, for Bætica, Corduba, for Lusitania, Emerita Augusta. We may see, in part, on what principles this division of the country was adopted. Lusitania and Bætica had tolerably distinct features, the latter having been from the earliest times the most civilized and the most tractable district of Spain. North of the Tagus came a much wilder region, the home of excitable and warlike tribes, this in great part, so as to include the country of the Celtiberi, was thrown into Tarraconensis, which, and also Lusitania, were under the empire “Cæsaris provincie,” the governors of them being nominated by the emperor. The smaller and quieter province of Bætica was a “senate's province,” and its finances were under the charge of the old republican official known as a “questor.” The governor of Tarraconensis seems to have held decidedly the first position in the country, he had as a matter of course the greater part of the army under his command, and he was usually, it may be presumed, an ex-censul. The governorship, indeed, of this province must have been one of the best appointments in the emperors' gift.

Under the empire Spain was divided for the general purposes included under the head of local administration into fourteen “conventus,” that is, provincial parliaments or assemblies made up of a union or combination of so many communities or townships. The town or city which was the centre of each “conventus” was the place where justice was administered to the inhabitants of the district, and would, so far, answer to our assize town. In Tarraconensis there were seven of these “conventus,”—Tarraco, New Carthage, and Cæsar Augusta being the chief, in Bætica, four,—Gades and Corduba being of the number, in Lusitania, the least populous and civilized district, three—Emerita Augusta the principal, Pax Julia, perhaps the modern Beja, and Scalabis not far from the mouth of the Tagus. Pliny (the elder), to whom we are indebted for these details, enumerates 360 cities in Spain in the time of Vespasian. These included every variety of township,—the “colonia” which originated in a camp or a settlement granted to old soldiers, the town whose inhabitants had all been made Roman citizens in the fullest sense (“municipium” in Roman phrase, under the empire), the town that had the inferior franchise (“jus Latii”), the “free town,” which might at any time have its freedom taken from it, and the “tributary” town (“civitas stipendiaria”). Spain presented types of all these various communities till Vespasian, it is said, gave them all the “jus Latii,” which opened an easy door for the provincials to the full privileges of citizenship. A native born Spaniard might now rise to the imperial dignity, as Trajan did, and the Spaniards generally must have felt themselves to all intents and purposes Romans.

The provincial constitution of Spain was revised and re-modified to some extent in the 2d century in the time, it would seem, of the Antonines and Hadrian. The vast and unwieldy province of Tarraconensis was subdivided, and the divisions distinguished as Gallaecia (the north-west), Carthaginiensis with New Carthage for its capital, Tarraconensis (the old name being then still retained for one division) with Cæsar Augusta for its capital, and the Balearic Isles, which had always been regarded as Spanish territory. Constantine accepted this arrangement, including, however, in it a strip of the western coast of Africa, part of the old Mauritania, which, from an ancient Moorish town, Tingis (Tangier), took the name of Tingitana among the later Roman provinces.

Spain in 256 A.D. was invaded and ravaged by the Frankish Franks, Tarraco was almost destroyed, and several flourishing towns reduced to mere villages. It was, how-

barians.

ever, but a passing storm,—the only interruption, in fact, to the peace and prosperity of the country during 400 years. With the departure of the Franks Spain soon recovered herself, and when we next hear of her early in the 5th century we find commerce and civilization well established, and cities ranking among the finest and richest in the Roman world. In 409, however, the year of the sack of Rome under Alaric, a tide of barbarism swept over the country, Suevi, Alani, Vandals "ravaged," says a writer of the time, quoted by Gibbon (ch 31), "with equal fury the cities and the open country." Spain, long so quiet and prosperous, was brought down to the lowest depth of misery. At this point the precise order of events is not quite clearly ascertainable. It seems that in 414 or 415 a Visigothic host entered Spain under their king, Ataulphus, Alaric's successor by election, who had married Placidia, the sister of Honorius, emperor of the West, son of the great Theodosius. Ataulphus was now Rome's ally, and fought as her champion in Spain against Suevi and Vandals. A new era seemed to have opened, and we may see in this alliance a prophecy of the ultimate fusion of Latin and German peoples,—the beginnings, in fact, of the modern world. To Ataulphus, who was murdered at his new capital Barcelona, succeeded after a brief interval in 415 Walla, a warlike and ambitious chief, who may be said to have established the Visigothic or West-Gothic kingdom in Spain on the ruins of the old Roman province. Walla concluded a treaty with the emperor Honorius, and, putting himself at the head of his brave Goths, in a three years' war he destroyed or drove into remote corners the barbarous hordes of Vandals, Alani, and Suevi that had settled down in the country. Spain, thus reconquered, was nominally subject to Rome, but soon became really independent and began to be the seat of a Christian civilization.

SECTION II.—SPAIN UNDER THE WEST-GOTHS

Walla.

The West-Gothic or Visigothic kingdom in Spain, founded by Walla, lasted for nearly three centuries, from 418 to 711, when it fell before the Arab or Saracen invasion. Toulouse was its headquarters, here was held the court of the West-Gothic kings, while Toledo became the centre of administration for Spain. The relations of the West-Goths with Rome varied from time to time sometimes they were her friendly allies, sometimes, nominally at least, her dependants, sometimes they rose in revolt and were her open enemies. Walla, after his victories in Spain, professed to restore the country as once more a Roman province to the rule of the emperor Honorius, and again we hear of the oppressions of imperial officers and functionaries, which seem to have been even more intolerable to the Spaniards than the strifes and wars of Vandals, Alani, and Suevi. Nor were these troubles finally ended, Walla had by no means thoroughly consolidated his conquests, and the West-Gothic kingdom in Spain cannot be said to have been firmly established till the 6th century. In northern Spain, in Galicia more especially, the Vandals and Suevi still had settlements, and were quarrelsome neighbours. In 428 they routed an allied army of Romans and Goths, and overran the southern districts, plundering some of the chief cities on the coast before they quitted the country for Africa under their king, the famous and savage Genseric. The Suevi yet remained, but at the solicitation of the Romanized Spanish provincials of the southern cities, who felt themselves threatened with utter extinction by these barbarians, Rome offered its intervention, which was effectually carried out by the king of the West-Goths, Theodoric II, grandson of Alaric. Crossing the Pyrenees in 456, as Rome's representative and ally, Theodoric crushed the Suevi by a decisive victory in the north west of Spain,

Theo-
doric.

near Astorga. It would seem that from this time the Suevic power was confined within the limits of Galicia, which became in fact a mere dependency of the West-Gothic kingdom. Theodoric's victories, so far from strengthening Rome's hold on Spain, greatly weakened it, and this was what he himself really intended. He did not even make a pretence of restoring the country to the imperial rule. His brother and successor Euric (466-485) Euric. persistently defied the empire, completing Theodoric's work, and establishing by further successes in Spain, carried into its remotest western districts, the West-Gothic kingdom in that country in full and avowed independence. Euric was something more than a successful warrior—he aspired to be a legislator, and he had the "customs of the Goths" recorded in writing and embodied in a code. The work was continued by his successor Alaric II in the beginning of the 6th century, under the superintendence of civil and ecclesiastical lawyers, and it was based mainly on what was known as the Theodosian code (see *BREVIAVIUM ALARICANUM*). The result was that a thoroughly Roman character was impressed on the West-Gothic legislation, and that Roman institutions, ideas, and manners long survived in Spain. With the conversion of the West-Goths from Arianism to the orthodox faith in the latter part of the 6th century, under their king Recared (586-589), came in new influences and a great accession of power to the ecclesiastics. Recared was the first Catholic king of Spain. With the zeal of a convert he set himself to root out Arianism, burning Arian books of theology and frightening his Arian bishops into the profession of the Catholic belief. He seems to have been thoroughly successful, and richly endowed churches and monasteries grew up in every part of Spain. Pope Gregory the Great acknowledged the good work of Recared by a gift of sacred relics. Unhappily the seeds of bigotry and religious intolerance had been sown, and with the beginning of the 7th century came a savage persecution of the Jews, multitudes of whom had long been settled in Spain and had thriven, as elsewhere, by trade and industry. The Jew up to this time seems to have found in Spain a particularly safe and comfortable home. Now, at the instance of a West-Gothic king, he was so cruelly oppressed and persecuted that even the Catholic clergy interposed to some extent on his behalf. A decree for the expulsion of the entire Jewish community was promulgated on one occasion with the sanction of the council of Toledo, but the Jew still held his ground in Spain and prospered and grew rich, and his presence in the country contributed to the rapid spread of Arab conquest in the next century.

The Jews
in Spain.

Among the most conspicuous features of the West-Gothic kingdom in Spain we may note elective monarchy, the great and indeed overshadowing power of the church, an aristocracy which had in its hands a very large part of the administration, a uniform code of laws for all Spaniards, with both a distinctly Roman and ecclesiastical impress on it. The church on the whole seems to have been the guiding spirit, and the Spanish bishops and clergy were held in high esteem for their learning and virtue. It was they who mainly inspired the legislation of the great national councils of Toledo, which to the West-Goths of Spain were what the Witenagemot was to our Saxon ancestors. The church was the centre round which the whole of society moved. In this fact we see foreshadowed much of the future of Spanish history, the supremacy of ecclesiastics, the extraordinary powers of the Inquisition. It had from the first its evil

³ Limited, however, to pure Gothic blood.

side in tendencies to bigotry and persecution, but it was at the same time the means of giving Spain laws very far above the average ideas of a barbarous people,—laws indeed which in many respects were rational, humane, enlightened, often combining the wisdom of old Rome with the kindly spirit of Christianity. The West-Gothic code recognized the equality of all men in the eye of the law, such barbarisms as the assessment of a man's value according to his rank and position, or judicial combat or trial by ordeal, find no place in it. It had certainly great merits, its weakness seems to have been in leaving too much scope on one side to the king, on the other to the clergy. Between the royal and the ecclesiastical powers individual freedom was liable to disappear. There was a danger, too, of human thought and speculation being wholly absorbed into theology. In anything like general literature Spain seems to have been decidedly poor during this period, while among her neighbours in the south of Gaul Greek philosophy was a fashionable study, testifying to the presence of considerable intellectual activity. Spain under its West Gothic kings and its Catholic clergy may have been a fairly well governed country, but long before the end came there must have been languor and decay amongst its people. After the conquest of Africa by Belisarius for the emperor Justinian, it seemed possible that the country might be once again annexed to the empire as a province, and an unsuccessful candidate for the throne,—which, it will be remembered, was elective,—went so far as to conclude a treaty of alliance, and actually to cede to the troops of the empire several towns on the Mediterranean coast. That a Gothic king should condescend to ask support from such a quarter, and allow himself to be spoken of as in any sense the empire's vassal, marks a very decided decline in the old independent spirit of the nation. We may certainly assume that repeated disputes as to the royal succession had undermined its power for resistance, and the numerous and not very well affected Jewish colony in their midst must have been a permanent source of danger. By the end of the 7th century northern Africa to the Straits of Gibraltar had passed wholly under Saracenic dominion. The struggle had been long and hard, and the West-Gothic kings, who had recovered the towns on the southern coasts, and even made some small conquests on the African shores, had done something to prolong it, but in 710 a little band of Saracens landed unopposed at Gibraltar, returned in safety, and urged their brethren at once to cross the straits and take possession of the country. In the following year (711) Tárik, at the head of about 5000 Saracen volunteers, entered Spain. A great Gothic army under Roderick, "the last of the Goths," was routed in the neighbourhood of Xeres on the Guadalete, and the Arab or Saracenic conquest of Spain, with the exception of the mountainous districts of the north, was accomplished with amazing ease and rapidity. Anything like a vigorous national resistance seems to have been too much for the Spaniards, enervated as they were by long familiarity with Roman civilization.¹ (W J B)

SECTION III.—MEDIEVAL HISTORY

The Arab invasion of Spain had been intended by Músá, the governor of Africa, to be merely a plundering raid (compare MOHAMMEDANISM, vol. XVI p 573). A single

¹ For the West Gothic kingdom in Spain, Gibbon's *Decline and Fall* should be consulted, chapters 31, 36, 37, 38, 41, 51. In note 122 (ch 38) he remarks on the obscurity of the subject, Spain having had during this period no chronicler like Bede for the Saxons or Gregory of Tours for the Franks. As to the West Gothic laws, there is a good deal of easily accessible information in Guizot's *History of Civilization*, lectures 3, 6, 10, 11. Compare ROMAN LAW, vol. XX p 712, and SALIC LAW, vol. XXI p 216, section (11).

unexpected success turned it into a conquest. Tárik had already made himself master of Cordova and Toledo when Músá arrived from Africa and rewarded his too successful lieutenant by consigning him to prison. But his military ability was too valuable to be dispensed with, and he was speedily released to aid in completing the conquest. Within four years the whole Peninsula, except the mountainous districts in the north, had submitted to the invaders. It was now Músá's turn to suffer from the jealousy of his superior. Recalled to Damascus by Walid, he arrived just after the caliph's death, and at once fell under the displeasure of his successor Suleimán. His sons, who had been left to rule in Spain, were involved in his disgrace, and the father died broken hearted on a pilgrimage to Mecca.

Few things in history are more remarkable than the case with which Spain, a country naturally fitted for defence, was subdued by a mere handful of invaders. The usual causes assigned are the misgovernment of the Visigoths, the excessive influence enjoyed by the clerical caste, internal factions and jealousies, and the discontent of numerous classes, and especially of the Jews. All of these doubtless co-operated to facilitate the conquest and to weaken the power of resistance, but the real cause is to be sought in the fact that the Visigoths had never really amalgamated with the conquered population. The mass of the inhabitants regarded their rulers as aliens, and had no reason to resent a change of masters. This feeling was strengthened by the conduct of their new conquerors. The Arab invasion undoubtedly brought with it considerable bloodshed and destruction of property, but it was merciful when compared with the previous incursions of the German tribes, and in the end it proved a blessing rather than a curse to the country. To all who submitted the Arabs left their laws and customs, and allowed them to be administered by their own officials. The cultivation of the fields was left to the natives, and the overthrow of the privileged classes gave rise to a system of small holdings or properties, which was one of the causes of the flourishing condition of agriculture under Arab rule. The slaves found their lot much improved under a religion which taught that the enfranchisement of a slave was a meritorious action. The Jews, as they had suffered most under the Visigoths, were the chief gainers from a conquest which they had greatly contributed to bring about. But nothing was so influential in securing ready submission to the Arabs as their tolerance in religious matters. Even the most bigoted adherents of Islam found a practical check to their zeal for proselytism in the loss that would accrue to the exchequer. The Christians had to pay a poll-tax, which varied according to the class to which they belonged. All property was subject to the *kharrá*, a tax proportioned to the produce of the soil, but converts to Mohammedanism were excused from the poll tax. A clerical chronicler of the 8th century, while bewailing the subjection of Spain to an alien race, says nothing against the conquerors as the professors of a hostile religion. His silence is an eloquent testimony to the haughty tolerance of the Arabs.

As time went on, and the Arabs felt more secure in their position, their rule became not unnaturally harsher. Many of the treaties which had secured favourable terms to the conquered were broken, and the Christians were provoked to resistance by persecution. A notable instance of this was the edict making circumcision compulsory for Christians as well as Moslems. Greater hardships still were endured by the "renegades," most of whom had embraced Mohammedanism from a desire for safety or for temporal gain, and who found that return to the old faith was blocked both to themselves and to their children by

Decline and fall of the West Gothic power

The Arab invasion

Causes of its success

Tolerance

the law which punished a perverted Mussulman with death. At the same time their social position was intolerable, and they were excluded from all lucrative offices and from all share in the government. Their discontent led to numerous and stubborn rebellions, but they belong to a later period, and in the 8th century the chroniclers record only a single rising, that of the Christians of Beja, and they seem to have been merely the tools of an ambitious Arab chieftain.

Moham
medan
discord.

It was fortunate for the Arabs that they succeeded at first in conciliating the natives, as otherwise their rule in the Peninsula would have been short-lived. Internal discord offered the Christians an easy opportunity for successful revolt if they had chosen to avail themselves of it. The conquerors were united by religion but not by race. When the task of conquest was achieved, and the need for unity was removed by the submission of the vast majority of the natives, quarrels arose between the various races which had taken part in the invasion. Besides the Arabs proper, who regarded themselves as the true conquering race, there were Berbers or Moors, Egyptians, and Syrians. So difficult was it to prevent their quarrels that it was found necessary to subdivide the conquered territory and to allot separate settlements to the different tribes, a measure which only tended to perpetuate their differences. Matters were made worse by the constant efforts of ambitious chieftains to raise themselves to power or to run their more successful equals. The first forty years of Arab rule in Spain are a period of woeful confusion, and it is difficult even to enumerate the names of the emirs who followed each other in rapid succession. The great empire of the Arabs began to fall to pieces as soon as it had reached its greatest extent. A movement whose end was conquest began to fail directly it ceased to conquer. The overthrow of the Omayyad dynasty by the Abbasids was a proof that disorder prevailed at the centre. The extremities inevitably displayed the same symptoms. Each new caliph sent a fresh emir to Spain, the governor of Africa claimed to interfere in the affairs of a province which had been conquered by one of his predecessors, and the native chiefs were often unwilling to submit to a new ruler whose arrival was the result of a revolution in which they had no share and which they would have prevented if they could. A capable and energetic governor, confronted with internal dissension and always dreading the arrival of a successor to supersede him, could only devise one way of solving the problem. The Arabs were unable to live at peace, and the one means of preventing them from warring with each other was to find them new lands to conquer. Hence came the frequent invasions of Gaul, now ruled by the degenerate Merwings, which resulted in the conquest of the provinces of Septimania and Narbonne, and at one time threatened to subject the whole of western Europe to the successor of Mohammed. But the battles of Toulouse (721) and of Tours (732) checked the advance of the Moslems, and by 759 they had been compelled to retire from all possessions beyond the Pyrenees. Thus thrown back upon the peninsula, it seemed probable that their empire in Spain would speedily succumb to the disruptive forces which had no longer any external outlet.

OMAYYAD.
Abd al
Rahman.

From this fate the Arab power was saved by 'Abd al-Rahmān (Abderame), the one survivor of the Omayyad dynasty, who succeeded after a long series of romantic adventures in escaping from the general massacre of his family (see vol. xvi. p. 578). His arrival in the Peninsula was welcomed by those Arab chieftains who had ends of their own to gain or who saw how impossible it was for Spain to be ruled from a distant centre like Damascus or Baghdad. The resistance of the Abbasid emirs, Yūsuf and 'Alī b. Moḡlith, was overcome, and 'Abd al-Rahmān was

enabled to found a new Omayyad dynasty at Cordova. He and his immediate successors seem to have contented themselves with the title of emir, but all connexion with the eastern caliphate was cut off, and Spain became independent under its new rulers. The reign of 'Abd al-Rahmān I was spent in almost constant warfare. No sooner had he reduced the southern provinces than a revolt broke out in Saragossa under Hosein b. Yahya. Driven from Spain, where he had raised the black standard of the Abbasid caliph, Hosein fled to the court of Charlemagne and implored his assistance. The Frankish army restored Hosein to power, but on its return was almost destroyed by the Basque mountaineers in the famous valley of Roncesvalles (778). After a siege of two years Saragossa was taken, Hosein was put to death as a rebel, and the whole country up to the Pyrenees was compelled to submit to the Omayyad. A formidable rising of the sons of Yūsuf was put down in 786, and 'Abd al-Rahmān was enabled to devote the last two years of his life to the arts of peace and to the construction of his famous mosque at Cordova. Before his death he settled the succession on his third son, Hishām, who had been born in Spain, and compelled his followers and his elder sons to swear fealty.

Hishām's reign, which lasted only eight years (788–Hishām 796), was comparatively uneventful. He was successful in foiling the attempt of his elder brothers to seize the throne, but a projected invasion of Gaul was repulsed by the courage of the count of Toulouse. Hishām was a devotee,—strict in the performance of religious duties and absorbed in works of charity. He completed the mosque which his father had begun, and endeavoured to make Cordova the educational centre of Islam. His son and successor, Al-Hakam, was of a very different temperament. Al-Hakam disregarded the precepts of the Koran which forbade the use of wine, and his lax practices irritated the *fakīhs*, the "scribes" of Mohammedanism. The inability of the Arabs to adapt themselves to a life of peace found expression in a number of isolated risings, of which the most notable took place in Toledo and Cordova. The inhabitants of Toledo had never forgotten that their city had once been the capital of Spain, and most of them belonged to the class of "renegades," who had no real attachment to the dominant faith. Al-Hakam determined to suppress their discontent by a notable act of cruel treachery. Feigning the most complete goodwill, he invited the chief citizens to a banquet in honour of the presence of his son in Toledo. As they entered the door they were conducted to an inner chamber and massacred by a band of assassins. More than seven hundred are said to have perished on this "day of the fosse" (807), and the citizens, deprived of their leaders, submitted with the torpor of despair. The fate of Toledo terrified the Cordovans, and postponed their rising for seven years. But in 814 the murder of a blacksmith by one of Al-Hakam's bodyguard provoked a terrible outbreak. Besieged in his palace by the infuriated mob, Al-Hakam only escaped death by his own coolness and presence of mind. A detachment of his guard was sent to fire the houses of the citizens, the mob hurried off to save their families and goods, and a sudden charge of the emir and his soldiers threw them into complete disorder. With politic severity Al-Hakam destroyed a whole quarter of the city and condemned all the inhabitants to exile. Part of them found a new home in Africa, but others, after a temporary sojourn in Alexandria, conquered Crete, where they founded a dynasty, which lasted till 961, when the island was recovered by the Greeks. The *fakīhs*, the real instigators of the rebellion, were treated with conspicuous leniency, and their leader, Talūt, was even admitted to Al-Hakam's favour.

CHRISTIAN STATES.

By the end of the 8th century it had become evident that the Arabs had committed a great error in not reducing the whole Peninsula, and that the contemptuous indifference with which they had left the northern mountains to a handful of refugees was destined to bring its own punishment. The early history of the Christian states of Spain is wrapped in a mist of fable and legend, but it is not hard to discern the main outlines. A scanty band of warriors, headed by Pelayo, probably a member of the Visigothic royal family, found refuge in the cave of Covadonga, among the inaccessible mountains of Asturias. Their own bravery and the difficulties of the country enabled them to hold their own, and they became the rallying point for all who preferred a life of hardship to slavish submission. The formation of a Christian kingdom was the work of Pelayo's grandson, Alfonso I, who seized the opportunity when the Arabs were occupied in the disputes attending the accession of 'Abd al Rahmān I. After driving the Berbers from Galicia, Alfonso advanced with his victorious troops as far as the Douro. But he had not followers enough to colonize the conquered territory, and contented himself with the northern districts, leaving a desert to form a natural boundary between himself and the Moors. Alfonso's son and successor, Fruela I (765-775), fixed his capital at Oviedo, but the greater part of his reign was occupied with the suppression of internal disorders, and he ultimately fell a victim to assassination. His throne was successfully usurped by his cousin Aurelia and his nephew Silo, both of whom sought security against domestic enemies in an alliance with 'Abd al Rahmān. On the death of Silo (781) a party among the nobles elected Fruela's son, Alfonso II, but for six years the western half of the kingdom obeyed a bastard son of Alfonso I by a Moorish captive, nicknamed from his origin El Maurecato. Under Alfonso the Chaste, whose long reign lasted till 842, the Christian kingdom of Oviedo was firmly established. It is impossible to find any accurate account of his achievements. The monkish chroniclers are hardly trustworthy authorities for military history, and they prefer to confine themselves to the more congenial subject of the founding and endowment of churches. The discovery of the pretended tomb of St James at Compostella is in their eyes the greatest event of the reign, and it undoubtedly aided to give a religious character to the war which was destined to be the great crusade of the west.

Alfonso II's reign witnessed the establishment of another Christian state in Spain. Charles the Great had been too much occupied elsewhere to avenge the great disaster at Roncesvalles, but he was only waiting for his opportunity. This was offered in 800 by the treachery of another governor of Saragossa, who had revolted against Al Hakam and sought assistance from the Franks. Charles himself was on his way to Italy to assume the imperial crown, but he sent his son Louis across the Pyrenees. In his first campaign Louis reached the Ebro, but he had to return in 801 to vanquish the obstinate resistance of Barcelona. The administration of the "Spanish mark" was entrusted to Bera, a man of Gothic descent, who proved fully capable of the task imposed upon him. The attacks of the Arabs were repulsed, and their last possessions beyond the Ebro were lost in 811, when Tortosa, after a siege of two years, succumbed to the forces which Louis the Pious had again led over the mountains. Henceforth the province was ruled by the counts of Barcelona, as representatives of the Frankish kings.

To avoid the difficulty of frequent transitions, it will be best to sketch in advance the main outlines of the history of the Christian states down to the formation of the three

kingdoms of Aragon, Castile, and Navarre, leaving their relations with the Moors to be narrated in connexion with the caliphate of Cordova. It is impossible to do much more than trace the dynastic and geographical changes, as their mutual quarrels are intricate and wearisome, and of little importance except as prolonging the rule of the Arabs in the Peninsula. The county of Barcelona may be dismissed with a few words. It continued for some time to be subject to Frankish suzerainty, and it suffered from the disorders that followed the break-up of Charles the Great's empire. Bera, its first count, was exiled, and his successor, Bernhard, played a prominent part in the intrigues of that troubled period. At one moment he added Septimania to the Spanish mark, at another he was disgraced and exiled, and finally he was treacherously murdered. In the later part of the 9th century all connexion with Septimania was cut off, and Wilfrid the Hairy (d 907) was able to make the county hereditary in his family. With its mixed population and its long line of coast the county of Barcelona, or Catalonia as it came to be called, was more involved in the affairs of Gaul than of Spain. Borengar I annexed the county of Carcassonne and other districts north of the Pyrenees (about 1050-1076), and Borengar III (1092-1131) obtained Provence by marriage. On the latter's death Catalonia and the transmontane territories were divided between his two sons, and in 1150 Borengar IV, by marriage with Queen Petronilla, obtained the kingdom of Aragon, with which Catalonia was henceforth united.

County of Barcelona (813-1150)

The history of Oviedo is more important and more complicated. Alfonso II's successors, Ramiro I (842-850) and Ordoño I. (850-866), had to contend both with the great nobles, who aimed at independence, and with the Basques, who had never learnt to submit to orderly rule. Alfonso III, in a long reign of nearly fifty years (866-910), won the title of "The Great" from the success which attended his arms. While his plundering raids extended as far as Coimbra and Lisbon, he really advanced his frontiers to the Douro, and in order to defend these more exposed territories he transferred his capital from Oviedo to Leon, on the further side of the mountains. In accordance with the universal custom of the Germans, Alfonso divided his territories among his three sons, Garcia receiving the southern districts with Leon as a capital, Ordoño II western Galicia, and Fruela II. the original district round Oviedo. In 931, however, the kingdom was again united under Ramiro II, a son of Ordoño II, and henceforth called after the new capital, Leon. Under Ramiro, a great warrior against the Arabs, we first hear of a district that was destined to become the most important in Spain. The border territory, a march to the south east of Leon, previously Bardulia, was now known as Castile, from the number of castles that had been raised to hold it against the infidels. Its count, Fernan Gonzales, was the most powerful noble in the kingdom of Leon, and sought to make himself independent. Ramiro reduced him to submission and then bound him to his side by marrying his eldest son to the count's daughter. Ordoño III (950-957) sought to emulate his father's achievements against the Arabs, but was hampered by the revolt of his brother Sancho and his father-in-law Fernan Gonzales. Sancho I (957-966) found an enemy in his recent ally, who attempted to place a rival king upon the throne, and he could only procure restoration to his kingdom by an alliance with the caliph of Cordova. This alliance lasted during the minority of his son, Ramiro III (966-982), who was deposed by the discontented nobles in favour of his uncle, Bermudo II (982-999). The latter, too mild a ruler for such troubled times, had a hard struggle against domestic

Kingdom of Oviedo or Leon

treachery and foreign enemies, and left a desolate kingdom to his son Alfonso V. Alfonso succeeded in restoring order, and to his reign are attributed the most important of the *fueros*, on which were based the local institutions of his kingdom.

Rise of
Navarre,
Castile,
and
Aragon. Meanwhile a new kingdom had sprung up to the east of Leon, which for a time seemed likely to become the chief state of Christian Spain. The district in the western Pyrenees bordering on the Bay of Biscay was the most defensible position in the Peninsula. It was there that the Basques had held out against the German invaders, and that the Suevi had found a refuge from the Visigoths. The sovereignty of the Moslems and of the Franks had been in turn acknowledged, but had never been more than nominal. About the beginning of the 10th century Sancho founded here the kingdom of Navarre, and he succeeded in extending his rule as far as the lower Ebro. His means of defence were primitive but efficient. When attacked by the infidels in overwhelming numbers he retired to the inaccessible mountains, and recovered the lost ground as soon as the enemy had turned his back. His grandson, Sancho the Great (970-1035), profited by the disasters which befel Leon. He married the sister of Garcia, count of Castile, and when his brother-in-law fell a victim to a conspiracy he seized the opportunity to avenge his death by annexing the northern portion of his country. In 1034 he picked a quarrel with Bermudo III. (1028-1037), the son and successor of Alfonso V., and conquered eastern Leon as far as the river Cea. More important still were his acquisitions in the south-east of Navarre. Partly by marriage connexions, and partly by the sword, he obtained possession of the counties of Aragon, Sobrarbe, and Ribagorça, which had for years been struggling to maintain their independence against the Mussulman governor of Saragossa. These considerable territories Sancho divided on his death (1035) among his four sons, and the division is an important event in the history of Spain. Garcia, the eldest, received Navarre, with a small district on the right bank of the Ebro, Ferdinand, the second son, obtained Castile, with the addition of the district of Palencia, which had been wrested from Leon, the counties of Ribagorça and Sobrarbe passed to Gonzalo, and that of Aragon to Ramiro, a bastard.

The death of Sancho the Great seemed to offer Bermudo III. an opportunity for recovering his lost territories, and he at once collected his forces to attack Ferdinand. In a pitched battle near the river Carrion, Bermudo was defeated and killed, and the conqueror at once annexed Leon with its dependencies—Galicia and Asturias—to his new kingdom of Castile (1037). The eldest brother, Garcia, resented a change which threatened to deprive Navarre of the pre-eminence which it had enjoyed under his father. To gratify his jealousy he did not scruple to ally himself with the emirs of Saragossa and Tudela. But in the battle of Atapuerca (1054) the unnatural coalition was defeated, Garcia lost his life on the field, and Ferdinand added to Castile the district on the right of the Ebro, leaving the rest of Navarre to his nephew, Sancho IV. Meanwhile Ramiro, equally ambitious and successful, got rid of his brother Gonzales, and seized upon Sobrarbe and Ribagorça to form, with his own inheritance, the kingdom of Aragon. Henceforth the history of Christian Spain centres round the two great states of Castile and Aragon. Leon, much to the disgust of its inhabitants, becomes a province of the former, and Navarre is soon afterwards deprived of independence by its more powerful neighbour.

We must now return to the history of the Arabs. Under 'Abd al Rahmān II (822-852), one of the mildest

and most cultivated of the Omayyad dynasty, began a Omayyad period of disorder and anarchy which might have ruined his power if the northern states had been prepared to take advantage of it. Toledo, which had recovered its independence soon after the "day of the fosse," was not reduced until after a desperate struggle of eight years, and then its fall was mainly due to internal quarrels. More serious was the growing spirit of insubordination among the Christian population of the south. In spite of the tolerance with which they were treated, the priests persisted in preaching against the rule of the infidel. Under the leadership of Eulogius and his friend Alvaro, a fanatical sect was formed which sought to emulate the glory of the early martyrs. So averse was the Government to resort to persecution that it was only by publicly blaspheming Mohammed that they could bring themselves under the penalties of the law. Eleven persons were put to death for such conduct, who are celebrated in Spanish history as the "martyrs of Cordova." It was in vain that the moderate party denounced their conduct as wanton suicide, the enthusiasts persisted in their defiant conduct. Mohammed (852-866), sterner and more narrow-minded than his predecessor, was not unwilling to take repressive measures, and the execution of Eulogius, who had been chosen archbishop of Toledo, seems to have checked for a time the thirst for martyrdom. But the movement had succeeded in provoking a feeling of distrust between the two religions, and it was difficult to return to the old attitude of easy tolerance. The "renegades" found their position altered for the worse, and under Mohammed they were jealously excluded from all the higher offices of state.

A series of revolts showed how prevalent was the feeling of discontent. The Gothic family of Bení Casí, which had embraced Mohammedanism in order to advance itself, had become extremely powerful in Aragon. Músá, the head of this family, made himself master of Saragossa, Tudela, and Huesca, concluded a close alliance with Toledo, which had again recovered its independence, and claimed to be the "third king in Spain." Músá's death in 862, in a war with Ordoño I. of Oviedo, enabled Mohammed to regain Tudela and Saragossa, but his troops were soon expelled by Músá's sons, and the Bení-Casí, with the help of Alfonso III., were for a long time able to bid defiance to the authority of the emir. About the same time an independent state was formed in the west by Ibn Merwān, a renegade of Merida. But by far the most formidable of these risings was that of 'Omar b. Hafsūn, who began as a brigand in the mountains of Andalusia, but whose castle at Bobastro became the centre of all the dissatisfied Christians and renegades of the south. Neither Mohammed nor his son and successor Mondhir (886-888) could reduce this impregnable fortress, and for years 'Omar was the real ruler of Andalusia. His authority was far greater than that of the emirs had ever been, his administration of justice was rude but efficient, and the Arab historians maintain that a girl laden with treasure could in his time cross the mountains in safety.

The premature death of Mondhir, a brave and chivalrous prince, gave the succession to his brother 'Abdallah (888-902), who ascended the throne at a very critical moment. Not only had the rising of the Christians and renegades assumed an almost national character, but the Arab nobles had taken advantage of the general disorder to assume the independence that was so congenial to them. 'Abdallah, considering the latter danger the more formidable, sought to gain over the Spaniards, and even offered Ibn Hafsūn the government of Regio, on condition that he would acknowledge himself as sovereign. But the negotiation came to nothing, and the only result was to

provoke the indignation of his own race against the omir. Luckily for him the Spaniards had an old debt to pay off against the Arabs, who had long treated them with insufferable contempt. In various districts a desperate civil war broke out, which was destructive of all law and order, but was not directly aimed against the central Government. The most violent struggle was in the province of Elvira, where for a time the natives got the upper hand, and it was only after a desperate conflict that the Arab domination was maintained by the heroism of two successive leaders, Sauwár and Sa'íd. In Seville a similar contest arose, and 'Abdallah, after attempting in vain to hold the balance between the two parties, was at last compelled to espouse the cause of the Arabs. An insurrection, in which the life of Mohammed, the emir's eldest son, was in imminent danger, was punished with ruthless severity, but it was the Arab nobles who profited by the success to make themselves absolute masters of the province. The central authority was almost powerless. Most of the provincial governors had thrown off all connexion with Cordova, and the others only rendered obedience when it was convenient to themselves. But at the moment when matters seemed at their worst the tide turned. In 890 'Abdallah won his first victory over Ibn-Hafsun, and during the remainder of his reign he gradually recovered power in the revolted provinces. The work was continued by his son and successor, 'Abd al-Rahmán (or Abderame) III (912-961), the greatest of the rulers of Cordova. Under this prince, who at last assumed the title of caliph, the unity of Mussulman Spain was for the time restored.

Abd al-Rahmán.

No sooner had 'Abd al-Rahmán completed the first part of his task by the reduction of the family of Ibn-Hafsun than he found himself confronted by two dangers. In Africa the Fatimites were establishing a great empire, and it was almost certain that they would turn their attention to Spain as soon as their power was secure in the southern continent. In the north the Christian states had profited by the long anarchy among their old foes and were assuming a very threatening attitude. Alfonso III had moved his capital across the mountains to Leon, and Sancho had recently created the kingdom of Navarre. As regards Africa, 'Abd al-Rahmán contented himself with encouraging and subsidizing the princes that still held out against the Fatimites, and with obtaining possession of Ceuta, so as to have complete command of the straits. The northern danger was the more pressing. In 914 Ordoño II made a successful raid into the territory of Merida, and two years later he defeated the army which had been sent to avenge the insult. Although Merida had not yet returned to submission, 'Abd al-Rahmán was determined to console his subjects by proving his ability to defend them. He spared no pains to collect a magnificent army, and his efforts were rewarded in 918 by a great victory over the combined forces of Leon and Navarre. This was the first of a series of successful campaigns, in the course of which he penetrated as far as Sancho's capital, Pamplona. But his victories brought him little beyond glory and revenge. As soon as his troops were withdrawn, the enemy showed himself to be really unconquered. In 921 Ordoño is said to have advanced within a day's journey of Cordova, and in 923 Sancho excited a panic in Mussulman Spain by the capture of Viguera. But the disorders in Leon that followed Ordoño II's death were a great blow to the Christians, and enabled 'Abd al-Rahmán to complete his work of internal reorganization and to turn his attention to resisting the Fatimite conquest of Mauretania. On the death of Sancho, his widow Tota recognized the caliph as suzerain of Navarre.

In his later years 'Abd al-Rahmán was less uniformly successful. The Arabs were disgusted by his policy of excluding the nobles from all share in the government and of filling the chief offices with "Slavs," the generic title for all foreign servants of the court. Ramiro II had succeeded in restoring unity to Leon, and resumed the warlike policy of his predecessors. In 939 he inflicted a serious defeat upon the army of the caliph at Alhandega, and was only prevented from following up his victory by a quarrel with the famous count of Castile, Fernán Gonzales. The divisions which followed Ramiro's death were an additional advantage to 'Abd al-Rahmán, and in 960 he gained the most conspicuous success of his reign when his troops restored the deposed Sancho I to the throne of Leon. This was almost his last act, as he died in October 961.

"Among the Omayyad princes of Spain 'Abd al-Rahmán III incontestably holds the first place. His achievements bordered on the fabulous. He had found the empire in a state of anarchy and civil war, divided amongst a crowd of chiefs of different race, exposed to constant raids from the Christians of the north, and on the verge of being absorbed either by Leon or by the Fatimites. In spite of innumerable obstacles he had saved Andalusia both from itself and from foreign rule. He had given to it internal order and prosperity and the consideration and respect of foreigners. He found the treasury in disorder, he left it in the most flourishing condition. A third of the annual revenues, which amounted to 6,245,000 pieces of gold, sufficed for the ordinary expenditure, another third was kept as a reserve, the rest was devoted to buildings. The condition of the country was equally prosperous. Agriculture, industry, commerce, the arts and sciences, flourished together. The foreigner was lost in wonder at the scientific system of irrigation, which gave fertility to lands that appeared most unpromising. He was struck by the perfect order which, thanks to a vigilant police, reigned in the most inaccessible districts. Commerce had developed to such an extent that, according to the report of the superintendent of the customs, the duties on imports and exports constituted the most considerable part of the revenue. A superb navy enabled 'Abd al-Rahmán to dispute with the Fatimites the empire of the Mediterranean, and secured him in the possession of Ceuta, the key of Mauretania. A numerous and well-disciplined army, perhaps the best in the world, gave him a preponderance over the Christians of the north. The most haughty sovereigns were eager for his alliance. Ambassadors were sent to him by the emperor of Constantinople and by the sovereigns of Germany, Italy, and France."—Dozy, iii 90.

The new caliph, Al-Hakam II (961-976), was distinguished as a patron of literature and a collector of books. The number of volumes in his library was reckoned at 400,000, and he is said to have read and annotated them all. For politics he had comparatively little taste. Naturally averse to war, he was only forced into hostilities by the obstinate refusal of Sancho I to fulfil the treaty which he had signed on his restoration, and he hastened to conclude peace on an empty renewal of the treaty. The disorders which arose during the minority of Ramiro III. put an end to all danger on the side of Leon, and the death of Fernán Gonzales in 970 removed a ruler who had always been a thorn in the side of the infidel. The most notable event of Al-Hakam's reign is the rise to influence of a man who was destined to play a more prominent part in the history of Spain than any of the caliphs, not excluding 'Abd al-Rahmán III. Mohammed Ibn abí-'Amr was the descendant of a family which had long been distinguished in the civil administration, but had never been admitted to the higher nobility of the sword. From his

Al-Hakam II.

treachery and foreign enemies, and left a desolate kingdom to his son Alfonso V. Alfonso succeeded in restoring order, and to his reign are attributed the most important of the *fueros*, on which were based the local institutions of his kingdom.

Rise of
Navarre,
Castile,
and
Aragon.

Meanwhile a new kingdom had sprung up to the east of Leon, which for a time seemed likely to become the chief state of Christian Spain. The district in the western Pyrenees bordering on the Bay of Biscay was the most defensible position in the Peninsula. It was there that the Basques had held out against the German invaders, and that the Suevi had found a refuge from the Visigoths. The sovereignty of the Moslems and of the Franks had been in turn acknowledged, but had never been more than nominal. About the beginning of the 10th century Sancho founded here the kingdom of Navarre, and he succeeded in extending his rule as far as the lower Ebro. His means of defence were primitive but efficient. When attacked by the infidels in overwhelming numbers he retired to the inaccessible mountains, and recovered the lost ground as soon as the enemy had turned his back. His grandson, Sancho the Great (970-1035), profited by the disasters which befell Leon. He married the sister of Garcia, count of Castile, and when his brother-in-law fell a victim to a conspiracy he seized the opportunity to avenge his death by annexing the northern portion of his country. In 1034 he picked a quarrel with Bermudo III. (1028-1037), the son and successor of Alfonso V., and conquered eastern Leon as far as the river Cea. More important still were his acquisitions in the south-east of Navarre. Partly by marriage connexions, and partly by the sword, he obtained possession of the counties of Aragon, Sobrarbe, and Ribagorça, which had for years been struggling to maintain their independence against the Mussulman governor of Saragossa. These considerable territories Sancho divided on his death (1035) among his four sons, and the division is an important event in the history of Spain. Garcia, the eldest, received Navarre, with a small district on the right bank of the Ebro; Ferdinand, the second son, obtained Castile, with the addition of the district of Palencia, which had been wrested from Leon; the counties of Ribagorça and Sobrarbe passed to Gonzalo; and that of Aragon to Ramiro, a bastard.

The death of Sancho the Great seemed to offer Bermudo III. an opportunity for recovering his lost territories, and he at once collected his forces to attack Ferdinand. In a pitched battle near the river Carrion, Bermudo was defeated and killed, and the conqueror at once annexed Leon with its dependencies—Galicia and Asturias—to his new kingdom of Castile (1037). The eldest brother, Garcia, resented a change which threatened to deprive Navarre of the pre-eminence which it had enjoyed under his father. To gratify his jealousy he did not scruple to ally himself with the emirs of Saragossa and Tudela. But in the battle of Atapuerca (1054) the unnatural coalition was defeated, Garcia lost his life on the field, and Ferdinand added to Castile the district on the right of the Ebro, leaving the rest of Navarre to his nephew, Sancho IV. Meanwhile Ramiro, equally ambitious and successful, got rid of his brother Gonzales, and seized upon Sobrarbe and Ribagorça to form, with his own inheritance, the kingdom of Aragon. Henceforth the history of Christian Spain centres round the two great states of Castile and Aragon. Leon, much to the disgust of its inhabitants, becomes a province of the former, and Navarre is soon afterwards deprived of independence by its more powerful neighbour.

We must now return to the history of the Arabs. Under 'Abd al Rahmān II (822-852), one of the mildest

and most cultivated of the Omayyad dynasty, began a period of disorder and anarchy which might have ruined his power if the northern states had been prepared to take advantage of it. Toledo, which had recovered its independence soon after the "day of the fosse," was not reduced until after a desperate struggle of eight years, and then its fall was mainly due to internal quarrels. More serious was the growing spirit of insubordination among the Christian population of the south. In spite of the tolerance with which they were treated, the priests persisted in preaching against the rule of the infidel. Under the leadership of Eulogius and his friend Alvaro, a fanatical sect was formed which sought to emulate the glory of the early martyrs. So averse was the Government to resort to persecution that it was only by publicly blaspheming Mohammed that they could bring themselves under the penalties of the law. Eleven persons were put to death for such conduct, who are celebrated in Spanish history as the "martyrs of Cordova." It was in vain that the moderate party denounced their conduct as wanton suicide; the enthusiasts persisted in their defiant conduct. Mohammed (852-866), sterner and more narrow-minded than his predecessor, was not unwilling to take repressive measures, and the execution of Eulogius, who had been chosen archbishop of Toledo, seems to have checked for a time the thirst for martyrdom. But the movement had succeeded in provoking a feeling of distrust between the two religions, and it was difficult to return to the old attitude of easy tolerance. The "renegades" found their position altered for the worse, and under Mohammed they were jealously excluded from all the higher offices of state.

A series of revolts showed how prevalent was the feeling of discontent. The Gothic family of Bení-Casí, which had embraced Mohammedanism in order to advance itself, had become extremely powerful in Aragon. Musá, the head of this family, made himself master of Saragossa, Tudela, and Huesca, concluded a close alliance with Toledo, which had again recovered its independence, and claimed to be the "third king in Spain." Musá's death in 862, in a war with Ordoño I. of Oviedo, enabled Mohammed to regain Tudela and Saragossa, but his troops were soon expelled by Musá's sons, and the Bení-Casí, with the help of Alfonso III., were for a long time able to bid defiance to the authority of the emir. About the same time an independent state was formed in the west by Ibn-Merwān, a renegade of Merida. But by far the most formidable of these risings was that of 'Omar b. Hafsūn, who began as a brigand in the mountains of Andalusia, but whose castle at Bobastro became the centre of all the dissatisfied Christians and renegades of the south. Neither Mohammed nor his son and successor Mondhir (886-888) could reduce this impregnable fortress, and for years 'Omar was the real ruler of Andalusia. His authority was far greater than that of the emirs had ever been, his administration of justice was rude but efficient, and the Arab historians maintain that a girl laden with treasure could in his time cross the mountains in safety.

The premature death of Mondhir, a brave and chivalrous prince, gave the succession to his brother 'Abdallah (888-902), who ascended the throne at a very critical moment. Not only had the rising of the Christians and renegades assumed an almost national character, but the Arab nobles had taken advantage of the general disorder to assume the independence that was so congenial to them. The central authority was almost powerless. Most of the provincial governors had thrown off all connexion with Cordova, and the others only rendered obedience when it was convenient to themselves. But at the moment when matters seemed at their worst the tide turned. In 890 'Abdallah won his first victory over Ibn-Hafsun, and during the remainder of his reign he gradually recovered power in the revolted provinces. The work was continued by his son and successor, 'Abd al-Rahmán (or Abderame) III (912-961), the greatest of the rulers of Cordova. Under this prince, who at last assumed the title of caliph, the unity of Mussulman Spain was for the time restored.

'Abd al-Rahmán.

No sooner had 'Abd al-Rahmán completed the first part of his task by the reduction of the family of Ibn-Hafsun than he found himself confronted by two dangers. In Africa the Fatimites were establishing a great empire, and it was almost certain that they would turn their attention to Spain as soon as their power was secure in the southern continent. In the north the Christian states had profited by the long anarchy among their old foes and were assuming a very threatening attitude. Alfonso III had moved his capital across the mountains to Leon, and Sancho had recently created the kingdom of Navarre. As regards Africa, 'Abd al-Rahmán contented himself with encouraging and subsidizing the princes that still held out against the Fatimites, and with obtaining possession of Ceuta, so as to have complete command of the straits. The northern danger was the more pressing. In 914 Ordoño II made a successful raid into the territory of Merida, and two years later he defeated the army which had been sent to avenge the insult. Although Merida had not yet returned to submission, 'Abd al-Rahmán was determined to conciliate his subjects by proving his ability to defend them. He spared no pains to collect a magnificent army, and his efforts were rewarded in 918 by a great victory over the combined forces of Leon and Navarre. This was the first of a series of successful campaigns, in the course of which he penetrated as far as Sancho's capital, Pamplona. But his victories brought him little beyond glory and revenge. As soon as his troops were withdrawn, the enemy showed himself to be really unconquered. In 921 Ordoño is said to have advanced within a day's journey of Cordova, and in 923 Sancho excited a panic in Mussulman Spain by the capture of Viguera. But the disorders in Leon that followed Ordoño II's death were a great blow to the Christians, and enabled 'Abd al-Rahmán to complete his work of internal reorganization and to turn his attention to resisting the Fatimite conquest of Mauretania. On the death of Sancho, his widow Tota recognized the caliph as suzerain of Navarre.

In his later years 'Abd al-Rahmán was less uniformly successful. The Arabs were disgusted by his policy of excluding the nobles from all share in the government and of filling the chief offices with "Slavs," the generic title for all foreign servants of the court. Ramiro II had succeeded in restoring unity to Leon, and resumed the warlike policy of his predecessors. In 939 he inflicted a serious defeat upon the army of the caliph at Alhandaga, and was only prevented from following up his victory by a quarrel with the famous count of Castile, Fernán Gonzales. The divisions which followed Ramiro's death were an additional advantage to 'Abd al-Rahmán, and in 960 he gained the most conspicuous success of his reign when his troops restored the deposed Sancho I to the throne of Leon. This was almost his last act, as he died in October 961.

"Among the Omayyad princes of Spain 'Abd al-Rahmán III. incontestably holds the first place. His achievements bordered on the fabulous. He had found the empire in a state of anarchy and civil war, divided amongst a crowd of chiefs of different race, exposed to constant raids from the Christians of the north, and on the verge of being absorbed either by Leon or by the Fatimites. In spite of innumerable obstacles he had saved Andalusia both from itself and from foreign rule. He had given to it internal order and prosperity and the consideration and respect of foreigners. He found the treasury in disorder, he left it in the most flourishing condition. A third of the annual revenues, which amounted to 6,245,000 pieces of gold, sufficed for the ordinary expenditure, another third was kept as a reserve, the rest was devoted to buildings. The condition of the country was equally prosperous. Agriculture, industry, commerce, the arts and sciences, flourished together. The foreigner was lost in wonder at the scientific system of irrigation, which gave fertility to lands that appeared most unpromising. He was struck by the perfect order which, thanks to a vigilant police, reigned in the most inaccessible districts. Commerce had developed to such an extent that, according to the report of the superintendent of the customs, the duties on imports and exports constituted the most considerable part of the revenue. A superb navy enabled 'Abd al-Rahmán to dispute with the Fatimites the empire of the Mediterranean, and secured him in the possession of Ceuta, the key of Mauretania. A numerous and well-disciplined army, perhaps the best in the world, gave him a preponderance over the Christians of the north. The most haughty sovereigns were eager for his alliance. Ambassadors were sent to him by the emperor of Constantinople and by the sovereigns of Germany, Italy, and France."—Dozy, in 90.

The new caliph, Al-Hakam II (961-976), was distinguished as a patron of literature and a collector of books. The number of volumes in his library was reckoned at 400,000, and he is said to have read and annotated them all. For politics he had comparatively little taste. Naturally averse to war, he was only forced into hostilities by the obstinate refusal of Sancho I to fulfil the treaty which he had signed on his restoration, and he hastened to conclude peace on an empty renewal of the treaty. The disorders which arose during the minority of Ramiro III. put an end to all danger on the side of Leon, and the death of Fernán Gonzales in 970 removed a ruler who had always been a thorn in the side of the infidel. The most notable event of Al-Hakam's reign is the rise to influence of a man who was destined to play a more prominent part in the history of Spain than any of the caliphs, not excluding 'Abd al-Rahmán III. Mohammed Ibn abí-'Ámir was the descendant of a family which had long been distinguished in the civil administration, but had never been admitted to the higher nobility of the sword. From his

Al-Hakam II

earliest youth he was inspired with the thought that he was destined to rule. His ability and the favour of Al-Hakam's favourite wife, Sobh, combined to bring about his speedy advance, and by the time of the caliph's death he held a high office in the court. Al-Hakam had done all in his power to secure the succession of his son by Sobh, Hishám, a boy of ten years of age. But the chief eunuchs, dreading the influence which a minority would give to Moshafi, the *hajib* or chief minister, sought to give the crown to Moghira, a brother of Al-Hakam. With the help of Ibn-abí-Ámir, Moshafi defeated the plot, Moghira was put to death, and Hishám succeeded to his father's throne. But he never really ruled. Ibn-abí-Ámir, still aided by Sobh, whose lover he was popularly supposed to be, gradually rose to absolute power. Moshafi, a man of little real ability, was charged with peculation and deposed, and his younger rival was appointed *hajib* in his place. To free himself from all danger from the mob at Cordova, the all-powerful minister transferred the government and the court to Zahra, which he built for the purpose. There the young caliph was immured in a magnificent palace, and was carefully secluded from all contact with public affairs. His education was purposely neglected, and he never made the slightest effort to free himself from his gilded imprisonment. To remove all obstacles to his authority, Ibn-abí-Ámir reorganized the army. He filled the ranks with Moors from Africa and with Spaniards from Leon, Castile, and Navarre, whom he bound to his cause by lavish generosity. The old tribal distinctions among the Arabs, so long the source of jealousy and quarrels, he completely disregarded in the forming of regiments, and thus completed the work of assimilation which 'Abd al-Rahmán III. had commenced. Though trained to the study of the law and experienced only in civil affairs, he speedily mastered the art of war and conciliated the popular favour by victories such as no caliph had ever won. In 981 he defeated Ramiro III. and his allies in a pitched battle, took Zamora and Sumanca, and was only prevented by a storm from capturing Leon. On his return he assumed the name of Almansór (victorious by the help of God), by which he is usually known in history. Bermudo II., whom the nobles of Leon raised to the throne in place of the defeated Ramiro, could only secure himself by paying tribute to the ruler of Cordova. In 985 Almansór invaded Catalonia, which had hitherto been respected as a Frankish fief, drove the count Borrel into exile, and took and sacked Barcelona. When Bermudo II. sought to free himself from the harsh conditions that had been imposed upon him and drove the Moslem troops from his kingdom, Almansór took a terrible revenge. In 987 he stormed Coimbra and razed it to the ground. In the next year he advanced into the heart of the kingdom. Leaving Zamora, where Bermudo awaited him, on one side, he marched against the city of Leon, and took it after an obstinate resistance. The fortifications were utterly destroyed, with the exception of one gate, which was left to commemorate the victor's triumph. Zamora was then attacked, and Bermudo fled to his northern territories, which were all that were left to him.

In spite of these successes Almansór had to face more than one conspiracy on the part of those who were jealous of his pre-eminence. The most formidable of these was fomented by his former patroness, Sobh, who found herself more and more thrust into the background. She succeeded in gaining over her son, but Almansór soon recovered his ascendancy over the feeble caliph, from whom he extorted a document transferring all powers to himself. A refusal of Bermudo II. to continue the payment of tribute led to the last and most famous of his campaigns,

in which he took Compostella and carried off the gates and bells from the shrine of St James, the patron saint of the Christians. At the same time his generals were gaining victories in Mauretania, and his power was almost equally dreaded on both sides of the straits. His death in 1002 deprived the Spanish Moslems of the greatest ruler and warrior, considering his origin, that their race had produced. His campaigns against the Christians, which are reckoned by the Arab historians as more than fifty, were almost uniformly successful. Three capitals—Leon, Pamplona, and Barcelona—had been conquered by him. His home administration was as successful as his generalship, and much of his attention was devoted to the construction of roads and bridges, so as to facilitate communication between all parts of Spain. He was a zealous, if not an intelligent, patron of literature, but his real interests were always practical. Finding that he was suspected by the people of a laxness in religious belief, he did not hesitate to prove his orthodoxy by an act of politic vandalism. Taking the chief *ulemá* into the library of Al-Hakam II., he begged them to collect all the books on philosophy, astronomy, and other prohibited sciences; and when they had completed their task he ordered the condemned books to be burnt on a vast pile.

Almansór had been absolute in everything but name. He had desired at one time to take the final step and to supersede the incapable Hishám II. in the caliphate, but he dreaded the inveterate attachment of the people to the Omayyad dynasty. He had, however, taken steps to secure the continuance of his family in power. His son, 'Abd al-Melik Mozaffar succeeded to the office of *hajib*, and ruled with the same authority and success as his father. But the position was really untenable. An hereditary monarchy is intelligible, but an hereditary line of chief ministers is not. The early death of 'Abd al-Melik (1008) gave the government to the weaker hands of his brother 'Abd al-Rahmán. The latter was hated by the Mohammedan clergy, partly because he indulged in the use of wine, and partly because his mother had been born a Christian. She was the daughter of a Sancho, either the king of Navarre or the count of Castile, and her son was nicknamed Sanchol, or the little Sancho. The Amirids were not popular. Their exaltation irritated, not only the families that claimed a higher rank by birth, but also those who thought themselves their equals. Without having any actual grievance to complain of, the people vaguely desired a change of rulers. It was easy under the circumstances to effect a revolution. When Sanchol returned from a campaign against Leon in 1009 he found that his power had been completely overthrown. Mohammed, a great-grandson of 'Abd al-Rahmán III., had headed an insurrection in the capital and had gained possession of the caliph's person. Sanchol was put to death, and the magnificent palace which his father had erected at Zahra was razed to the ground. The Amirids fell, and with them ended the grand period in the history of Moslem Spain.

Mohammed was not long content with the office of *hajib*. Scrupling to kill the unfortunate Hishám, who had never made any opposition to the acts that had been committed in his name, he closely imprisoned him, and buried the corpse of a Christian who bore a strong personal resemblance to the caliph. Mohammed was now raised to the caliphate, and assumed the title of Al-Mahdí (guided by God). But his reign was not destined to be long or untroubled. He had been raised to power by a combination of orthodox Moslems, of the so-called "Slavs" (foreign slaves serving in the royal harem and in the army of the caliph) and of Berbers, and he alienated each in turn. The Berbers, who formed an important part of the army, were the first to revolt. Raising the standard of Solei-

Al-Hakam II.

mán, a member of the Omayyad family, they obtained assistance from Count Sancho of Castile, marched upon Cordova, and inflicted a serious defeat upon the troops which Mohammed imprudently led out to meet them. Mohammed endeavoured to strengthen his position by producing Hishám II, whom he had given out as dead. But the Berbers refused to be turned from their purpose, and occupied Cordova in November 1009. The wretched Hishám was compelled to abdicate in favour of Soleimán, and returned to his prison. Mohammed, who had escaped to Toledo, now turned for assistance to the Christians, who, by a sudden change of circumstances, had become the arbiters of Mohammedan affairs. With the help of troops from Catalonia he recovered Cordova, which had to pay in constant sieges a terrible penalty for the levity with which it had welcomed the fall of the Amírs. In pursuing the Berbers, however, Mohammed was again defeated. The Slavs, who had hitherto supported him for their own ends, determined to desert the unsuccessful caliph. Hishám II was again dragged from prison to assume the throne, and Mohammed was murdered in his presence. Wálih, the leader of the Slavs, was now *hajib*, and aspired to play the part of Almansór. But his resources were at an end. An attempt to increase the taxes roused general indignation, and he was put to death by his own followers (1011). Two years later the nominal reign of Hishám II came to an end. Cordova was taken by Soleimán and the Berbers, and the caliph disappeared (1013). His fate remains one of the unsolved secrets of history.

Soleimán Soleimán was now formally proclaimed caliph, but his power was more nominal than real. The provincial governors had taken advantage of the civil war to make themselves independent, and Soleimán's authority was only recognized by five towns—Cordova, Seville, Niebla, Osasonoba, and Boja. Even within this district he soon found an opponent. The Slavs were unwilling to submit to the domination of the Berbers, whose excesses the caliph was unable to check. Their most powerful leader, Khairán, had been badly wounded in the late struggle, but on his recovery he determined to avenge his defeat. He found a capable ally in 'Alí b Hammúd, a descendant of the famous son-in-law of the Prophet, but whose family had almost ceased to be Arab in their long residence in Africa. 'Alí relied not only upon the Slavs but also upon the Berbers, who regarded Soleimán with contempt, and looked upon 'Alí as a fellow-countryman. Soleimán's government was easily overthrown (1016), but Khairán's attempt to discover Hishám II was unsuccessful, and he had to acknowledge 'Alí as caliph and to content himself with the office of *hajib*.

Ham-mudites. The Hammudite dynasty, thus established in Cordova, was not destined to enjoy a long tenure of power. Khairán revolted against a sovereign who was too able and spirited for the part of a Hishám II, and set up an anti-caliph in the person of another Omayyad, 'Abd al-Rahmán IV, a great-grandson of 'Abd al-Rahmán III, who took the name of Mortadá. 'Alí was murdered in his bath (1017), but his supporters rallied round his brother Kásim. For five years a confused civil war raged which was complicated by the hostility to Kásim of 'Alí's son, Yahyá. In 1023 Mortadá was slain in battle, and the Omayyad party gave the crown to another 'Abd al-Rahmán, a brother of the detestable Malidí. Two months later the young prince was murdered, but his successful rival, Mohammed b 'Abd al-Rahmán was driven from Cordova in 1025. The Hammudite caliph, Yahyá, now occupied the capital, but was slain in attempting to reduce the rebellious *wáls* of Seville to obedience. Hishám III, a brother of 'Abd al-Rahmán Mortadá, was now raised to the throne. But all central government

was by this time at an end, no revenues could be drawn from the rebellious provinces, and in 1031 Hishám abdicated a title which had ceased to have any meaning, and sought peace and retirement in the neighbourhood of Saragossa. His death five years later was almost unnoticed even in Cordova. With him ended the Omayyad dynasty, which had ruled in Spain for nearly three centuries, and which had produced princes worthy to be ranked with the greatest of their contemporaries. Its decline dates from the time when it allowed power to slip from its hands and to be wielded by ambitious ministers.

Ever since the death of Almansór Moslem Spain had been gradually splitting up into a number of independent principalities. With the extinction of the Omayyads the last semblance of unity disappeared. "The Berber generals shared the south, the Slavs ruled in the east, the rest was divided either among successful adventurers or among the small number of noble families who had been fortunate enough to escape the blows which 'Abd al-Rahmán and Almansór had struck at the aristocracy. Finally, the two most considerable towns, Cordova and Seville, were organized as republics" (Dozy). Into the history of the numerous dynasties which were established during this period it is impossible to enter here, but the reader will find the subject not only fully but attractively treated in the fourth volume of Dozy's *Histoire des Musulmans d'Espagne*. See also Plato VII.

It was of additional moment that this disruption of the States of Mussulman power was contemporary with the formation of the great Christian states of Aragon and Castile. They were not slow to profit by the opportunity held out to them. It was in this century that the Christian cause found a champion in the famous Ruy Diaz Campeador, who under the name of "The Cid" became the traditional hero of Spanish mediæval history. Ferdinand I of Castile (1037-1067) captured the strong places of Visen, Lamego, and Coimbra, and was only diverted from the conquest of Toledo by the humble submission of the emir, who undertook to pay tribute to the Christian king. The unfortunate division of his territories between his three sons gave occasion to civil wars, which were only terminated in 1072 by the reunion of the whole kingdom under Alfonso VI. Following up his father's successes, Alfonso made himself master of Toledo, which once more became the capital of a Christian state. Meanwhile Ramiro I of Aragon (1035-1063) drove the Moors from their last possessions in the counties of Aragon and Sobrarbe. His son, Sancho Ramirez (1063-1094), joined Alfonso VI in an attack on Navarre which resulted in the partition of that state between the two kings, and commenced a war against the emir of Saragossa which ended, under his successors Pedro (1094-1104) and Alfonso I (1104-1136), in the conquest of Huesca and Saragossa. The latter town became henceforth the recognized capital of Aragon.

This period is also important in another aspect. Hitherto the Christian kingdoms of Spain had been naturally isolated from the rest of Europe. But the papacy, under the guiding hand of Hildebrand (Gregory VII), was now making its ecclesiastical supremacy a reality, and was not likely to tolerate independence even in the most distant members of the church. Aragon, which lay nearest to the other states of Western Christendom, made little difficulty about complying with the papal demands. Ramiro not only agreed to adopt the Roman ritual in his kingdom, but even sent tribute to Alexander II. Castile, lying farther distant, was more inclined to resent dictation. At a council at Burgos (1077) it was formally decided to retain the Gothic ritual. But Alfonso VI realized the danger of isolating his state from the rest

Castile and Aragon formed

Relations with Rome.

of Europe, and of his own accord conceded the demands of Gregory VII. From this time Christian Spain was directly connected with Rome, and became the most faithful, if not the most servile, of Roman Catholic countries.

Almoravid campaigns in Spain (1069-91)

The Christian victories of the 11th century seemed likely at one time to annihilate the Mohammedan power in Spain. From this fate, however, it was saved, not by any internal strength, but by the arrival of assistance from Africa. The emir of Seville, Al Mo'tamid, the most powerful of the Moslem princes, watched with profound misgiving the progress of the Castilian arms. When Toledo fell before Alfonso VI. he determined to appeal to Yûsuf b Tâshufin, the king of the Almoravids,—a confederation of Berber sectaries that had recently established a vast empire reaching from the Senegal to Algiers. Yûsuf, who had established his capital at Morocco in 1069, was at this time eighty years of age, but he did not hesitate to accept the prospect of a new field of conquest and adventure. In 1086 he sailed from Ceuta to Algesiras, the cession of which he had demanded as the price of his aid, and was at once joined by the forces of the emirs of Andalusia. Alfonso VI. hastened to obtain assistance from the king of Aragon and the count of Barcelona, and with a larger force than had ever before been assembled in the Christian cause he met the Moors in the battle of Zallâka (Sacralias), a few miles from Badajoz (October 1086). After an obstinate struggle victory declared for the infidels, and Alfonso had great difficulty in escaping with his life. Luckily for the Castilians, Yusuf was recalled to Africa by the death of his eldest son, whom he had left at Ceuta, and his victory, which might have been as decisive as that of Târik, was not followed up. Alfonso even ventured to resume his aggressions, and laid siege to the important towns of Murcia and Almeria. Mo'tamid, seeing that the danger was as great as ever, proceeded to Africa in person in order to urge the return of Yûsuf. The Almoravid prince, on whom the attractions of Andalusia had made a profound impression, crossed again to Algesiras (1090), and this time the predictions of the princes who had foreseen the risk of calling in so powerful an ally were fully verified. Postponing the task of resisting Alfonso, Yûsuf set to work to make himself master of Andalusia. Mo'tamid himself had to fly from his territories, after a futile appeal for aid to the king of Castile. Captured by the Africans, the emir of Seville was condemned to end his life in close imprisonment. In the course of a few years the whole of Moslem Spain was rennited under the king of Morocco, and the death of the Cid in 1099 enabled the Moors to recover Valencia, which he had taken in 1094. This was the last event of the reign of Yûsuf, who in 1103 handed over the government to his son 'Alî and returned to Africa, where he died three years later at the ripe age of a hundred years.

Alfonso VI. of Castile.

Alfonso VI. of Castile had raised his kingdom to such pre-eminence in the Peninsula that he had assumed the title of "emperor of Spain." But a great disaster clouded his later years. In 1108 his only son Sancho perished with the flower of the Castilian chivalry on the fatal field of Ucles, and most of Alfonso's conquests passed into the hands of the victorious 'Alî. In 1109 the emperor died, leaving the succession to his daughter Urraca, the widow of Count Raymond of Burgundy. In order to secure the unity of the Christian kingdoms, Urraca was married to Alfonso I. of Aragon (1104-1134), who imitated his father in law in assuming the imperial title. But the marriage failed to produce the desired result. Urraca induced the Castilian nobles to revolt against the Aragonese rule and to set up Alfonso VII., her son by her first marriage. A civil war ensued, which was only ended

Temporary union of Castile and Aragon

in 1127 by the separation of the kingdoms. Alfonso I. retained Aragon and Navarre, while Castile, with Leon and Galicia, passed to Alfonso VII. Alfonso of Aragon renewed the war against the Moors which he had so gloriously begun by the capture of Tudela and Saragossa, but in 1134 he was completely defeated in the battle of Fraga, a disaster which hastened his death. As he had no children, he bequeathed his territories to the great crusading order of the Templars. The Aragonese, however, refused to recognize this testament, and gave the crown to his brother, Ramiro II. (1134-1137), who was brought out of a monastery to continue the dynasty. Ramiro fulfilled his duties by marrying a sister of the duke of Aquitaine, who bore him a daughter, Petronilla. At the age of two the child was betrothed to Raymond Berengar IV of Barcelona, and Ramiro, leaving the administration of the kingdom to his son-in-law, hastened to return to his cloister. Thus a permanent union was effected between Aragon and Catalonia, both of which passed in 1162 to Petronilla's son, Alfonso II. But, if Catalonia was gained, another province, Navarre, was lost. The Navarrese had long desired to recover their independence, and on the death of Alfonso I. they refused to acknowledge Ramiro, and chose a ruler of their own, Garcia Ramirez. Ramiro, who needed Garcia's generalship against a threatened attack from Castile, recognized him, first as a vassal of Aragon and afterwards as an independent king. Thus Navarre regained its place among the kingdoms of Spain, though it never enjoyed its old importance.

Navarre independent

The main interest of Spanish history in the 13th century centres round the war against the Moors, which was beginning to attract the interest and assistance of the other European states. It was the age of the great crusades, and Christendom was absorbed in the struggle against the infidel, both in the East and West. Spain, like Palestine, had its crusading orders, which vied with the Templars and Hospitalers both in wealth and military distinction. The order of Calatrava was founded in 1158, that of St James of Compostella in 1175, and the order of Alcantara in 1176. The kingdom of Portugal, which had risen with great rapidity in the 12th century, had a no less distinguished order, that of Evora. These military priests, debarred by their profession from the ordinary interests of humanity, gave a firmness and consistency to the Christian cause which had too often been sacrificed to the dynastic quarrels of the temporal princes.

Crusading orders

The empire of the Almoravids, like so many of its predecessors, had soon begun to fall to pieces. It was too large and unwieldy for permanence. Its real centre was at Morocco, and the attention of the caliphs was absorbed in the affairs of Africa, while the extortion and misgovernment of their viceroys excited discontent among the Mohammedans of Spain. This state of things gave a great advantage to Alfonso VII. of Castile, who revived the title of emperor of Spain, allied himself with Raymond Berengar of Barcelona and Aragon, and sought to emulate the achievements of his grandfather. For the second time the Moorish power in Spain was only saved from dissolution by the arrival of reinforcements from Africa. As happened so often in Mussulman history, a movement which began with religious reform ended with the formation of an empire. Mohammed b 'Abdallah, an Arab from Mount Atlas, gave himself out as the expected Mahdi, and formed a sect known as the Almohades (Unitarians). His disciple, 'Abd al M'n'min, was chosen as his successor, and soon overthrew the power of the Almoravids. Tâshufin, 'Alî's son, made a vigorous but ineffectual resistance, and the conqueror crossed the sea to complete his work by the reduction of Spain (1146). The success of 'Abd al M'n'min, if less rapid than that of Yûsuf,

Struggles of Almoravids and Almohades.

Separation of Castile and Leon

was quite as complete. The Almoravids appealed to the Christians, and both Castile and Aragon came to their aid. Alfonso VII, with the help of the Genoese and Pisan fleets, besieged and took Almeria, while Raymond Berengar captured Tortosa. But these successes were only temporary. In ten years the Almoravids had been driven from the mainland, and only a small remnant found refuge in the Balearic Islands. Almeria was again wrested from the Castilians, and in 1157 Alfonso VII died, the last of the series of "emperors of Spain." His territories were divided between his two sons, the elder, Sancho, succeeding to Castile, while Leon went to his brother Ferdinand. The quarrels which resulted from this partition would probably have been fatal to the Christian cause but for the exertions of the great knightly orders. The successors of 'Abd al-Mu'min (d. 1163), Yusuf and Ya'qub Almansor, continued to advance the power of the Almohades, and the latter inflicted a crushing defeat at Alarcos (1195) upon Alfonso VIII of Castile, who had succeeded his father Sancho in 1158. Castile was at this time distracted by the feuds of the great families of Lara and Castro, and the count of Castro, who had been worsted by his rival, rendered conspicuous service to the infidels in the battle. Even Sancho of Navarre, out of jealousy of the rival kings, concluded an alliance with the Almohades.

Downfall of the Almohades

Luckily for the Christians Ya'qub, the most formidable opponent they had had to face since the great Almansor, died in 1199, and his death was followed by a rising of the Almoravids which took five years to suppress. Meanwhile successful efforts had been made by the pope and clergy to arrange the differences among the Christian states, and a confederation was formed between the five kings of Castile, Aragon, Leon, Navarre, and Portugal. When Ya'qub's successor, Mohammed al-Nasir, had succeeded in restoring order in Andalusia and prepared to march against the Christians, he was confronted by the allies in the famous battle of Las Navas de Tolosa, in the Sierra Morena (July 16, 1212). After an obstinate struggle the Christians gained a decisive victory, and their success decided the fate of Spain. The religious impulse which had constituted the original strength of the Almohades had come to an end, they were regarded as infidels by the orthodox Moslems, and the first failure necessarily led to their downfall. The cruelties with which they sought to repress the rising discontent only excited popular feeling against them, and when Al-Motawakkil, a descendant of the family of Ibn Hud which had once ruled in Saragossa, raised the standard of revolt in Andalusia, the bulk of the population joined him, and Al-Ma'mun, the last of the Almohades who held any power in Spain, fled to Africa in 1232. The chief result of their rule was to depress the Arab element in the Muslim population of Spain. Hitherto the Arabs, though numerically in a minority, had retained the preponderance due to their original prestige. Henceforth the infidels of Spain can only be considered and spoken of as Moors.

Castile and Leon reunited.

After the fall of the Almohades the triumphs of the Christian arms were rapid and decisive. The separation of Castile and Leon, which had been productive of so much disaster, was finally terminated in 1230 by the accession of Ferdinand III, the son of Alfonso IX of Leon and Berengaria of Castile. The province of Estremadura had been annexed to Leon by Alfonso IX, and now formed part of the united kingdom which under Ferdinand III rapidly extended itself southwards. In 1233 the Castilian army won a great victory over the Moors under Al-Motawakkil, and three years later Ferdinand himself captured Cordova, so long the capital of the Mohammedan rulers and one of the most wealthy and

beautiful cities of Europe. In 1237 Al-Motawakkil was assassinated, and with him perished the last semblance of Moorish unity. The numerous emirs became independent rulers, and the most powerful of them, Mohammed Ibn al-Ahmar of Granada, became a tributary of Castile and ceded the strong town of Jaen (1246). In 1248 Sevilla, the second of the Mohammedan cities, submitted to Ferdinand, who within a few years annexed Xerez de la Frontera, Medina Sidonia, and Cadiz. By these acquisitions the frontier of Castile was extended to the southern coast before Ferdinand III's death in 1252. A considerable number of Moors submitted to the rule of Castile, but the Christians had become intolerant during the long war, and most of the conquered population sought a new home either in Granada or in Africa.

Meanwhile Aragon had taken a no less important part in the struggle. Pedro I (1196-1213), the successor of Alfonso II, had excited the discontent of his subjects, partly by seeking coronation from Pope Innocent III, and partly by his excessive taxation. The "union" of nobles and towns compelled the king to diminish his exactions. Pedro took part in the battle of Navas de Tolosa, but his attention was diverted from Spanish affairs by his relationship with Raymond of Toulouse, which involved him in the Albigensian crusade, where he met his death. His son James I (1213-1276), however, resumed the war against the infidels, and won in it the title of "The Conqueror." With the help of his Catalan subjects, at that time perhaps the most accomplished sailors in the world, he conquered the Balearic Islands (1229-1233), which had long been a stronghold of the Moslem and a centre for piratical attacks upon the Christian states. Still more important was his reduction of Valencia (1238), which had once before been conquered by Ruy Diaz. The last achievement of the great king was the conquest of the province of Murcia (1266), the last of the Moorish territories in Spain except Granada. Murcia, though reduced by Aragon, was handed over to Castile. By the acquisition of Algarve Portugal had already acquired frontiers which correspond roughly to those which it has at the present day.

From the latter half of the 13th century the crusading energy of the Spaniards came to a sudden standstill, and the Moors were allowed to retain possession of Granada for more than two centuries. The causes of this abrupt termination of the war before it had reached what seemed to be its natural and legitimate end have often been discussed. In the first place Castile was henceforth the only state which was directly interested in the war. By the acquisition of Seville and Murcia it had separated Granada both from Portugal and Aragon, neither of which states had henceforth any common frontier with the Moors. The state of Granada, though small when compared with Castile, was by nature easily defensible, as was made amply apparent in the last campaigns under Ferdinand and Isabella. The attention of Castile was often distracted by foreign interests or by internal dissensions. Again, the Moors were more concentrated and homogeneous in Granada than they had been when their rule was more extensive. The large subject population, many of whom were Christians or renegades, had been a great source of weakness, and thus no longer existed. They, like their opponents, had given up the tolerance that had once distinguished them, and hardly any but true Mohammedans can have remained in Granada. Something, too, must be attributed to the wily policy and well timed submission of Mohammed Ibn al-Ahmar, who even gave assistance to Ferdinand III against the other Moorish emirs.

With the termination of the crusade Spanish history loses what little unity it had possessed for the last two

Moorish Granada centuries, and it becomes necessary to follow the fortunes of each state separately. Into the history of Granada it is as impossible as it would be tedious to enter within the limits of this article. It is a long record of revolution and civil war, in which nothing above the most petty personal interests are concerned. There is no change of dynasty, but one perpetual struggle between members of the same family. It would not be easy to enumerate even the names of the successive rulers, many of whom were several times deposed and restored to power. Even during the final struggle, when the existence of the kingdom was at stake and the one hope of resistance lay in unity, the national cause was sacrificed to the jealous rivalry of three claimants of the throne. The history of Castile and Aragon, on the other hand, assumes a new character and interest when the attention of kings and people ceased to be absorbed in the overwhelming excitement of a great religious war.

CASTILE (1252-1479)
Constitution of the kingdom

The constitution of Castile traced its origin back to the institutions of the Visigoths, which had been carried by the original refugees into the mountains of Asturias, but it had been profoundly modified by the circumstances under which the kingdom had risen to greatness. The war with the infidel, while it had given strength and unity to the monarchy, had at the same time compelled the granting of considerable independence to the nobles and the great towns. The religious character of the war had enabled the clergy to retain greater powers than they possessed in any other European country, though they had lost that omnipotence which they had enjoyed under the Visigoths. Their councils and synods, which had once formed the sole constitutional machinery of the country, had been superseded by the secular assembly of the cortes. The early history of the cortes is wrapped in great obscurity, but its main outlines are fairly discernible. Originally a meeting of the great nobles and royal household, it had attained the position of a national assembly in 1162, when the deputies of the chief towns were admitted to membership. Its powers and procedure developed gradually, and naturally varied according to the character of the different kings. Its first functions were the approval of legislation and the granting of extraordinary taxation, though it is difficult to say when its sanction of such measures was regarded as essential. The assembly consisted of the three estates—clergy, nobles, and citizens—who deliberated sometimes separately and sometimes together. Representation existed only in the case of the third estate, whose members were elected at first by all free citizens and afterwards by the municipal magistrates. The number of cities which sent deputies varied very much at different times. As to what constituted the right of attendance in the case of the nobles and clergy, there is great obscurity, but it probably depended partly upon tenancy in chief and partly upon royal summons. As both classes were exempt from taxation, their functions were less important than those of the third estate, and on more than one occasion we find meetings of the cortes in which the upper orders took no part. The weakness of the assembly, as contrasted with the English parliament, lay mainly in the absence of any class like the knights of the shire to form a link between the burgesses and the great nobles. In early times, probably the most effective check upon the royal power lay in the independent privileges claimed and exercised by the chief feudatories. Their tenants were bound to feudal service, and the right of private war made them petty sovereigns on their own estates. The long feud of the families of Castro and Lara is only a notable example of the difficulties which the central power had to contend with. For the protection of their privileges, both nobles and towns claimed

the right of forming an armed union or *hermandad*, which resembled the right of "confederation" exercised in later times by the nobles of Poland. The ordinary administration, except when war was going on, was local rather than central. The nobles had judicial powers within their domains, though it appears that these were granted by the crown rather than derived from their territorial position. The bishops and higher clergy administered ecclesiastical jurisdiction as in other countries, and at the same time exercised the same powers as the secular lords over the large estates which the piety or superstition of generations of benefactors had conferred upon them. The connexion with Rome, though established in the 11th century, had not become very close before the middle of the 12th century. The appointment to most of the bishoprics was in the hands of the crown, and the church of Castile was more independent even than that of England. In the cities and great towns, most of which were of considerable extent of adjacent territory, the administration of justice and of local affairs was in the hands of municipal corporations which had received grants of liberties at the time when they had received as important privileges as the attack of the infidel. In the city, probably, there existed in all cases a right of appeal to the crown, but this was a right which, in the nature of things, was rarely exercised. The attempt of municipal lords to control or supersede the local administration of justice by the appointment of *corregidores* was always regarded as an encroachment upon traditional liberties. Even the taxes, though granted by a central authority, were raised and collected by the local officials and jealous care was taken to secure that they should only be applied to the purpose for which the grant had been made.

Ferdinand III, "the Saint," was succeeded in 1252 by his son, Alfonso X, "the Wise." The new king gave up the military policy of his father, and the only territorial acquisition of his reign, the province of Murcia, was won for him by the arms of Aragon. On the other hand he was a great student and patron both of literature and science, especially of astronomy. He invited to his court the most distinguished scholars not only in Christian but also in Arabic lore, and he raised the university of Salamanca to rank with the great schools of Paris and Oxford. He also turned his attention to legislation, and his code, the *Siete Partidas*, is one of the great legislative monuments of an age which produced the *Provinciale* of St Louis and the great statutes of Edward I. Compiled under the influence of the civil and canon laws, the *Siete Partidas* was in some respects disadvantageous, especially as admitting papal encroachments upon the ecclesiastical power of the crown. Though drawn up under Alfonso X, it did not finally supersede the ancient *Siete* until 1318, when it was formally approved by the cortes. But Alfonso's reign, though distinguished in the history of literature and law, was not on the whole a prosperous period for Castile, and it was to a great extent his fault that the opportunity of driving the Moors from the Peninsula was allowed to slip. On the fall of the Hohenstaufen he came forward as a candidate for the imperial dignity, and through the period known as the "great interregnum" he and Richard of Cornwall, chosen by rival parties among the electors, bore the empty title of king of the Romans. The expense of bribing the electors and of maintaining a magnificent court involved Alfonso in pecuniary difficulties and compelled him to alienate his subjects by imposing heavy taxes and by debasing the coinage. But the hardships inflicted on the country by the king's futile ambition were as nothing compared with those which arose from a disputed succession to the crown. By the old custom of Castile nearness

of blood gave a superior claim to priority of descent, so that the second son of a king would be preferred to the children of the eldest son. The *Siete Partidas* recognized the more modern rule of succession; but, as that code had not yet been accepted by the cortes, its ruling had no binding force. The question arose in 1275, when Alfonso's oldest son, Ferdinand de la Cerda, perished in a campaign against the Moors, leaving two sons, Ferdinand and Alfonso. The king's second son, Sancho, was at once declared heir to the crown, but the widow, Blanche, announced her intention to uphold the rights of her children, and she received support both from Pedro III of Aragon and from her brother, Philip III of France. A long war followed, which was further complicated when Alfonso X, having quarrelled with his son, proposed a partition between the rival claimants. So far did the dispute go that the Moors, instead of being attacked in Granada, were called upon to give their assistance to the factions among their enemies.

Sancho
V.

Ferdinand
V.

The result of these internal quarrels was to increase the already excessive power of the noble families, and this was productive of further disturbances in the reign of Sancho IV (1284-1295). The family of Castro seems to have sunk into comparative insignificance, but the Laras had found a new rival in the house of Haro. The whole state was divided by their feuds, and the king found himself degraded from the position of arbiter to that of a partisan. The condition of affairs became even worse when the death of Sancho gave the crown to his infant son Ferdinand IV (1295-1312). In an early stage of society a minority is always an evil, and Castile at this period had more than a fair share of such misfortunes. The crown was contested, not only by the late king's brother John, but also by Alfonso de la Cerda, who returned from France to maintain a claim which had already been negatived by the accession of Sancho. The king of Aragon supported Alfonso, while the rulers of Portugal and Granada mixed themselves up in the quarrel to obtain advantages for themselves. The regency had been bequeathed by Sancho to his widow, Maria de Molina, but her marriage had been declared uncanonical by the pope, so that a slur was cast upon the legitimacy of her son. Nothing but the great skill and capacity displayed by the regent could have secured victory under such discouraging circumstances. By mingled submission and defiance she disarmed one opponent after another, induced the pope to ratify her marriage, and finally succeeded in transferring the government to her son on his coming of age. Ferdinand's harshness provoked a renewal of the conflict, but ultimately the treaty of Camillo (1305) put an end to the struggle, and compensated the princes of La Cerda with lavish cessions of territory. Alfonso preferred to remain an exile rather than to abandon his claims, but his son accepted the proffered conditions and became the founder of the great house of Medina Sidonia. But the treaty made little difference to the country. Disorder and civil war had become a chronic disease in Castile, and Ferdinand IV was himself too deeply imbued with the spirit of the age to maintain peace with a strong hand. The story that is told about his death illustrates his character. In spite of a solemn promise made twice during his reign that every accused person should have a fair trial, he ordered two brothers of the name of Carrizal to be put to death without the pretence of judicial forms. They summoned him to appear before the supreme tribunal within thirty days, and on one morning within that period he was found dead in his bed. The cause of his death was never ascertained, but the people regarded the event as a judgment, and he has received from this story the name of "The Summoned" (*El Emplazado*).

Ferdinand IV's death was followed by another and still

longer minority, as his son, Alfonso XI (1312-1350), Alfonso was only two years old at the time. The regency was claimed by the late king's brother Don Pedro and by his uncle Don John, and from this dispute arose a civil war fiercer and more destructive than any of its predecessors. The central authority ceased to exist, both nobles and towns had to protect themselves as best they could, the royal domains were seized upon by rapacious neighbours, and the person of the young king was only saved by his being concealed in the cathedral of Avila. At last the mediation of the pope and of Maria de Molina brought about a compromise, and the administration was divided between the two regents,—Pedro taking the south eastern and John the north-western provinces (1315). But a few years later they were both killed in a joint campaign against the emir of Granada, and the disorders broke out with worse violence than ever (1319). Four "infants," as the members of the royal family were called, contended for the government, and the assumption of power by the king himself at the age of fifteen failed to put a stop to their feuds. The character of Alfonso XI was as harsh and brutal as was to be expected in a man who had been educated in such troubled times. He invited his cousin, a younger Don John, to a banquet in the royal palace, and treacherously murdered him. His treatment of his first wife, whom he divorced in order to marry a daughter of the king of Portugal, provoked her father, Don John Emanuel, a nephew of Alfonso X, to head a rising which took years to suppress. The Portuguese princess was also repudiated by her husband, who had been inspired with a passion for the beautiful Eleanor de Guzman, and the forces of Portugal were added to those of the Castilian rebels. After a long struggle (1335-1337) Alfonso XI succeeded in reducing his opponents to submission, while he conciliated Alfonso IV of Portugal by restoring his daughter to her position as queen. The restoration of unity was extremely opportune, as Spain was threatened at this moment by a new invasion from Africa. Abu'l Hakam, the head of the Merinids and emir of Fez, crossed over to Gibraltar with a huge army in 1339, and was acknowledged as suzerain by the ruler of Granada. Assistance was obtained both from Aragon and Portugal, and in 1340 Alfonso XI marched to the relief of Tarifa, which was besieged by the Moors. On the banks of the Salado the Christians won a great victory, which destroyed the last chance of a revival of the Mohammedan power in Spain. Abu'l Hakam fled to Africa, and in 1344 Alfonso concluded a glorious war by the reduction of Algeiras. In the hope of cutting off all connexion between Granada and Africa, Alfonso laid siege to Gibraltar in 1350, but before he could accomplish his design he was carried off by the Black Death. His victories over the infidel have led the Spanish historians to gloss over the acts of cruelty and treachery which have left an ineffaceable stain upon his character. His reign, troubled as it was, constitutes an important epoch in the history of Castilian liberties. In 1328 he issued two laws which formed the firmest basis of the powers of the cortes. He recognized the right of that assembly to be consulted in all important matters of state, and he solemnly pledged himself and his successors not to impose any new tax without its approval and consent. These concessions were to some extent counterbalanced by his restriction of the right of electing deputies to the *regidores* or magistrates of each city. This narrowing of the franchise was a great blow to the popular rights, and it gave the crown facilities for tampering with the elections which were frequently abused in later days. But at the time the municipal magistrates enjoyed considerable independence, and for several generations the cortes showed no signs of subservience. In fact

Alfonso's position made him dependent upon the support of the citizens against the great lords, so that he was not likely to aim at diminishing the power of the former class. Another important event of the reign was the granting by the cortes, for the expenses of the Moorish war, of the *alcavala*, a tax of a twentieth upon every sale of real or personal property. This tax, one of the most ruinous that can be conceived, illustrates the want of economical insight in the 14th century, and was destined in later times to seriously impede the industrial and commercial development of Spain.

Pedro I The atrocities of Alfonso XI's reign sink into insignificance when compared with those committed by his son and successor, Pedro I. (1350-1369). The story of the latter's rule is mainly derived from the narrative of his avowed enemies, but there is no reason to doubt the substantial accuracy of the charges which have given him the name of "The Cruel." Some of his actions may perhaps be attributed to a politic desire to destroy the ascendancy of the great nobles, whom the princes of the royal house had often headed against the crown, but most of them can only be explained by a thirst for bloodshed which almost amounted to mania. He ascended the throne at the age of sixteen, and was at once urged by his mother Maria of Portugal to avenge the wrongs which she had endured at the hands of her rival, Eleanor de Guzman. The unfortunate Eleanor was strangled in prison, and her sons could only secure safety by flight. The eldest, Henry of Trastamara, found a refuge first in Portugal and afterwards in France. A wife was now found for the young king in Blanche, daughter of the duke of Bourbon, in the hope of strengthening his throne by a French alliance. But Pedro had formed a connexion with Maria de Padilla, and when he was at last induced to go through the marriage ceremony with Blanche, he quitted her immediately to return to his mistress, whose brothers he advanced to the chief offices of state. A conspiracy of nobles, headed by Alfonso of Albuquerque, lately the king's favourite, was suppressed with ruthless severity. Pedro now concluded a second marriage with Juana de Castro, although Blanche was still living, but he again returned to Maria de Padilla. Another conspiracy, backed up by the pope and the French king, was more successful. After standing a long siege in Tordesillas, Pedro was compelled to concede the demands of the coalition and to acknowledge Blanche as his lawful queen. But his submission was only feigned. Seizing the opportunity of a hunting-party to escape from the imprisonment in which he was kept at Toro, he rallied a mercenary army round him and took terrible vengeance upon his opponents (1355-56). Henry of Trastamara, who had joined in the rising, escaped to France, where he took part in the war against the English. It would be wearisome to catalogue the long list of cruelties, beginning with the murder of the unfortunate Blanche of Bourbon, of which Pedro was guilty during the next ten years. It seems almost incredible that such a monster should have been allowed to reign in a country which had already shown so much independence as Castile. But several causes combined to secure him against deposition. In the first place, it was upon the nobles and the Jews that his hand fell with such severity, while to the citizen class he was on the whole a lenient ruler. This explains why it was that the cortes made little or no opposition when he endeavoured to secure the succession to his own children. In 1362 he solemnly swore that he had been lawfully married to Maria de Padilla, and his four children by her were recognized as heirs to the crown. His son Alfonso, however, died in the same year, and only two daughters, Constance and Isabella, survived their father. Another point in Pedro's favour was the outbreak in 1356 of a war

with Aragon, which lasted almost without intermission for the rest of the reign, and in the course of which the Aragonese king was joined by Henry of Trastamara. Much as the Castilian nobles hated Pedro, they hated Aragon still more, and they were unwilling to accept a king who might seem to be forced upon them by the neighbouring kingdom. This war was in a way harmful to the interests of both kings. They were both eager to depress the powerful nobles in their territories, but their continued hostilities only enabled these nobles to extend their power. On more than one occasion this community of interest was on the verge of leading to an agreement which would probably have excluded the house of Trastamara for ever from Castile, but each time national and personal enmity combined to revive the quarrel. Though Castile was larger and possessed of more resources than its rival, the presence of a large number of Castilian exiles in Aragon made the combat fairly even. But in 1365 Henry of Trastamara obtained new and more formidable auxiliaries. Charles V of France, who was now beginning to reorganize that country after the English wars, was only too glad to allow the disorderly bodies of disbanded soldiers to seek employment in Spain under the leadership of Bertrand du Guesclin. To these formidable enemies Pedro did not venture to offer resistance, and fled to Bayonne, while his half brother Henry was everywhere acknowledged as king (1366). But Pedro succeeded in convincing the Black Prince of the justice of his cause and of the impolicy of allowing the French king to gain overwhelling influence in the Peninsula. Before the end of the year Edward's army had crossed the Pyrenees, a number of English mercenaries in Du Guesclin's service deserted to the banner of their old leader, and in April 1367 was fought the great battle of Najera or Navarrete, near Logroño. Du Guesclin was taken prisoner. Henry of Trastamara fled to France, and Pedro was restored to his throne. But the Castilian king had learnt no wisdom from adversity. His barbarity disgusted his allies, who were further alienated by his failure to furnish him promised supplies. The fever had already begun to decimate his troops and to weaken his own health when the Black Prince quitted Castile. His departure gave another opportunity to Henry of Trastamara, who had obtained fresh reinforcements from Charles V. In 1369 the battle of Montiel was decided in Henry's favour. Pedro was taken prisoner, and was killed in a personal struggle with his rival, into whose tent he was brought. His two surviving daughters had been left as hostages at Bordeaux, and were married to two brothers of the Black Prince, — John of Gaunt, and Edmund Langley, duke of York.

Henry II. (1369-1379) was of illegitimate birth, and Henry II's marriage with the heiress of the La Cerda was hardly sufficient to remove all doubts as to his claim to the succession. But within his kingdom he met with little opposition. The Castilians were glad to settle down under an orderly government after the late reign, and the few malcontents eviled themselves to join the foreign claimants of the throne. The most important of these was Pedro I of Portugal, whose grandmother belonged to the legitimate line of Castile, and John of Gaunt, who came to Spain to vindicate the rights of his wife Constance. Pedro I proved for a time a formidable enemy. He allied himself with the Moors, who seized the opportunity to recover Algeiras, and with the king of Aragon, who annexed the border districts of Castile. But Pedro was an incapable warrior, and soon abandoned his own claim to obtain the English support by acknowledging John of Gaunt. But this enabled Henry to renew his alliance with France, and with the help of French troops he invaded Portugal, besieged Lisbon, and compelled Pedro to make peace

John I

Two years later a treaty was concluded with the king of Aragon, by which his conquests were restored. For the remainder of his reign Henry's throne was secure, and he left the kingdom in peace to his son John I (1379-1390). The chief interest of the now reign centres round the relations with Portugal. The first renewal of the war was the work of the Portuguese king Ferdinand, who again supported the English claims upon Castile. But the alliance with England was not popular in Portugal, and in 1383 a treaty was concluded, which, however, proved productive rather of evil than of good. Beatrice, the only daughter of Ferdinand, was married to the Castilian king, and it was agreed that her children, whether male or female, should succeed to the throne of Portugal. A few months later Ferdinand died. Beatrice was at once proclaimed queen, and her mother undertook the regency. But the idea of union with Castile, which would involve the subordination of the smaller kingdom, was intensely unpopular at Lisbon. A rising overthrew the authority of the queen mother, and the administration was entrusted to John, a brother of the late king. John of Castile at once entered Portugal to enforce what he considered to be the rights of his wife. But his high-handed measures only added strength to the opposition, and made the new regent the leader of a national movement. In 1384 the Castilian forces laid siege to Lisbon, which held out with obstinate resolution for five months, when the besiegers retired. Exulting in their success, the Portuguese determined to have nothing more to do with Beatrice, and an assembly of the cortes gave the crown to the regent John. The Castilian king now made a determined effort to uphold his failing cause, but at the great battle of Aljubarrota (August 1385) his army suffered a crushing defeat. It was now the turn of the Portuguese to take the aggressive, and the arrival of John of Gaunt enabled them once more to take up his cause. It was only the aid of France and the dislike of the Castilians for the foreign-bred Constance and her husband that enabled John to make head against his numerous enemies. In 1387 he succeeded in terminating the English part of the quarrel. His eldest son Henry, the first heir to the crown who received the title of prince of Asturias, was betrothed to Catherine, daughter of Constance, in whose favour John of Gaunt renounced all claims on behalf of his wife (1387). The war with Portugal now sunk into a chronic struggle on the frontier, but was still going on when John I died in 1390.

Henry III

With the accession of Henry III (1390-1406), a boy of eleven, Castile was again face to face with the difficulties of a minority, and these were the more formidable on account of the absence of any prince of the blood royal to assume the regency. By the will of the late king the administration was entrusted to a council to be formed by joint representation of the three estates. But the composition of this body was altered so as to give more power to the great nobles and prelates, and their quarrels soon involved the kingdom in the troubles of a civil war, from which it had been comparatively free in the last two reigns. Luckily for Castile, the young king, who assumed the government in 1393, showed himself to be a man of equal insight and resolution. By throwing himself boldly upon the support of the third estate, and by giving them the predominance in the cortes, he succeeded in taking efficient measures against the nobles. All domain lands which had been alienated during his minority had to be restored, and all confederations among the barons were declared illegal and dissolved. The discontent which these measures provoked was promptly suppressed before it could develop into insurrection. At the same time the country enjoyed the blessings of external peace. Henry's marriage with Catherine of Lancaster secured him against

hostilities not only from England but also from Portugal, whose queen was Catherine's sister. Unfortunately for the kingdom which he ruled with such wisdom and success, Henry III died in 1406 at the early age of twenty-seven, leaving an infant son to succeed him.

The minority of John II was the most orderly period of his reign (1406-1454). The government was wielded by the able hands of his uncle Ferdinand, to whom the Castilians would have given the crown if he had been willing to supplant his nephew. Even after his accession to the throne of Aragon in 1412 he continued to give his advice to the queen-mother. The administration during these years was strong and orderly. The fortress of Antequera was taken from the Moors, and the Castilian nobles were kept in the same subjection as in the late reign. A new and disastrous period commenced in 1417, when the death of his mother transferred the reins of government to John II at the age of fourteen. Averse to the cares of business and absorbed in personal pleasures, the young king was only too ready to allow himself to be guided by any one who would take the responsibility of rule upon his own shoulders. Before many years had elapsed he had fallen completely under the influence of Alvaro de Luna, grandmaster of the order of St James and constable of Castile. The minister, possessed of all the qualities which would have endowed a great monarch, set himself to increase the royal power. Not only were the nobles depressed to a condition of impotence which they had never yet experienced, but steps were also taken to diminish the powers of the third estate. Many of the lesser towns in Castile, as in England at the same period, found that the right of representation involved pecuniary burdens which they were eager to get rid of. This made it easy for the minister to reduce the number of towns sending deputies to the cortes to some seventeen or eighteen of the larger cities. This diminution of the third estate, though not resented, was an insidious blow at its real interests, and made it easy for Charles V and his successor to reduce the cortes to impotence. The arbitrary government of John II, which might have been endured if it had been really directed by the king himself, was intolerable to the nobles when it was known to be inspired by his minister. The reign is filled by a series of conspiracies, in which the domestic malcontents found powerful allies in John II's cousins, John and Henry of Aragon. But Alvaro de Luna was a warrior as well as a politician, and succeeded in foiling all direct attempts to effect his overthrow. His ultimate fall was due to the ingratitude of the king whom he had served too well. John's second wife, Isabella of Portugal, disgusted at the small amount of influence which the minister allowed her to exercise, set herself to effect his overthrow. Once deprived of the royal favour, Alvaro de Luna had no further support to rest upon. The very absolutism which he himself had built up was turned against him, and he was executed after a trial which was notoriously unfair. A year later John II followed him to the grave, and the crown passed to his son, Henry IV, the feeblest sovereign that ruled in Castile before the 17th century. His mind was as feeble as his body, and the contempt of his subjects has fixed upon him the title of "The Impotent." His first favourite, the marquis of Villena, was supplanted, after Henry's marriage with Joanna of Portugal, by Beltran de la Cueva, whom scandal declared to be the queen's paramour. The birth of a daughter did nothing to check these rumours, and the unfortunate infant was only known as "la Beltraneja." The government was not exactly oppressive, but it failed to command respect, and personal jealousies and ill feeling were sufficient to produce a revolt. The leaders were the marquis of Villena

and Carillo, archbishop of Toledo, both of whom had objects of their own to serve. In 1465 the rebellion broke out, and its first act was the formal deposition of Henry at Avila, after an absurd ceremony in which the king was represented by a puppet. The conspirators denounced the infanta Joanna as illegitimate, and offered the crown to Henry's brother Alfonso. In the course of the civil war which followed, Alfonso died (1468), and his partisans at once put forward the claims of his sister Isabella. But the infanta, who already displayed a wisdom and moderation beyond her years, refused to be involved in hostilities with her elder brother, and she succeeded in arranging a treaty by which she was recognized as Henry IV's heiress. The king himself struggled hard to evade these conditions, and after his death in 1474 Joanna's cause was espoused by her uncle, Alfonso V of Portugal. But Isabella succeeded in securing her accession to the throne, and her marriage with Ferdinand of Aragon, by paving the way for the union of the two kingdoms, begins a new period in which for the first time there is a real history of united Spain.

Isabella.

ARAGON
(1213-
1479)
Constitution.

The kingdom of Aragon which we left in the reign of James the Conqueror (1213-1276), consisted of the three provinces of Aragon, Catalonia, and Valencia. Each province retained its own laws and institutions, and Valencia and Catalonia regarded with the keenest jealousy any attempt to govern them on the principles which prevailed in Aragon. The powers of the crown were far more limited than in the neighbouring kingdom of Castile. The great nobles, or *ricos hombres*, formed a small and exclusive class, whose privileges made them almost the equals of the monarch. All conquests had to be divided between them, and the king was forbidden to confer a fief or honour upon any person outside their ranks. They possessed and exercised the right of private war, and were entitled at will to renounce their allegiance to their sovereign. The smallness of their numbers made them much more united than the nobles of Castile, and proportionately more formidable. The difference between the two kingdoms was recognized by Ferdinand the Catholic with his usual acuteness when he said that "it was as difficult to divide the nobles of Aragon as it was to unite those of Castile." But the privileges of the nobles, great as they were, were not the only check upon the royal power. Each province had its own cortes, which possessed from a very early date the right of granting taxes and approving legislation. In Valencia and Catalonia the cortes consisted, as in Castile, of the ordinary three estates, but in Catalonia, where a maritime life had inspired the inhabitants with a passionate love of freedom, the commons enjoyed a predominance which was hardly to be paralleled in any other country in the Middle Ages. The cortes of Aragon, which were more important, and whose history has been more carefully elucidated, consisted of four estates or arms (*bracos*). Besides the great prolates and the *ricos hombres*, both of whom had the right of appearing by proxy, there was a separate chamber of smaller landholders. This contained the *infanzones*, or lesser tenants-in-chief, and the *caballeros* or knights, who were tenants of the greater barons but whose military rank gave them the right of personal attendance. The fourth chamber alone was representative, and consisted of the deputies of the towns. Their presence is first mentioned in 1133, thirty years before anything is heard of popular representation in Castile. Their numbers were naturally small, as the kingdom was of very limited extent, but it seems to have been early established that a town which had once sent deputies was permanently entitled to the privilege, and thus preserved them from having their rights tampered with by the crown as was

done in Castile. Besides their legislative and taxative functions, the Aragonese cortes were also a supreme court of justice, and in this capacity were presided over by the *justicia*, an official whose unique powers have attracted the attention of all writers on Spanish history. In its origin the office had nothing very remarkable about it, and it is only the peculiar circumstances of the kingdom which forced it into such prominence. The *justicia* was not at first entrusted with any political functions, but the difficulty of adjusting the relations between the king and the barons led to his being called in as mediator. By the 11th century he had become almost the supreme arbiter in all constitutional questions. To him the people could appeal against any infringement of their liberties, while the king regarded him as his chief councillor and as the most efficient barrier against armed rebellion, which was the only alternative method of settling disputes between his subjects and himself. As the *justicia* thus became the pivot of the constitution, it was of great importance to secure that he should exercise his functions with firmness and impartiality. As the *ricos hombres* were exempted from corporal punishment, he was always chosen from the lesser nobles or knights, and was made responsible to the cortes under penalty of death. The dignity of the office was enhanced by the character of its successive holders, and the medieval history of Aragon abounds with instances of their fearless opposition to the crown and of their resolute resistance to despotism on the one hand and to anarchy on the other.

The glorious reign of James (I) the Conqueror was disturbed towards its close by quarrels which arose from his scheme of partitioning his conquests among his children. The death, however, of his youngest and favourite son put an end to these projects, and the most important of the provinces passed into the hands of Pedro Pedro III (1276-1285). Under Pedro and his son and successor Alfonso III (1285-1291), attention was almost wholly diverted from internal affairs to the conquest of Sicily. By his marriage with Constance, the daughter of Manfred, Pedro could put forward a claim to succeed to the Hohenstaufen in Naples and Sicily, but it is not probable that he would have been able to make any use of the claim if the Sicilian Vespers (1283) had not thrown that island into his hands. The result was a long series of wars with the Angevin rulers of Naples, but the hold upon Sicily was steadily retained. These wars had a notable influence upon Aragonese history, as they compelled the kings to purchase the support of their subjects by concessions which could only with great difficulty have been extorted from them. Thus in 1283 Pedro III granted the famous "General Privilege," the Magna Carta of Aragon. By this the crown formally laid down a number of rules to secure all classes against oppression. The General Privilege is quite as important a document as the English charter, it is even more full and precise, and its numerous confirmations show that it was as highly prized. It had the additional advantage of being issued to a people already possessed of institutions sufficiently developed to employ and defend the national liberties. But if Pedro's concessions were for the advantage of his country, his successor went to an extreme which was equally harmful. In 1287 Alfonso III signed the famous "Privilege of Alfonso Union," by which his subjects were formally authorized to take up arms against their sovereign if he attempted to infringe their liberties. The right of revolt, while it is and must be the ultimate safeguard against oppression, becomes at once liable to abuse when it is formulated and discussed. The act of 1287 gave an unlimited licence to disorder, which could always disguise itself under the pretence of defending liberty. Until it was repealed

there was always a danger that the constitution would succumb, not to the tyrannical usurpations of the crown, but to the selfish interests of the nobles

II. On the death of Alfonso III the crown passed to his brother James II (1291-1327). The new king handed over Sicily to his younger brother Frederick, thus creating a separate dynasty in that island. In the hope of depressing the greater barons, James II strengthened the hands of the justiciar and sought to conciliate the clergy and citizens to the crown. By these steps he succeeded in avoiding any open conflict during his reign, and at the same time he sought to secure external unity by an edict which declared the three provinces of Aragon, Catalonia, and Valencia to be for ever indivisible (1319). But his successor, Alfonso IV (1327-1336), did not hesitate to break this edict, in spirit if not in letter, by carving out great fiefs for his second wife, Eleanor of Castile, and her children. By this measure he gave rise to the difficulties, and indirectly to the triumphs, of his son, Pedro IV (1336-1387). Pedro's reign is a great epoch in Aragonese history, as to him is due the arrest of the tendencies which threatened to divide and destroy the kingdom. He began by recalling his father's excessive grants to his stepmother and his half-brothers. The intervention of Alfonso XI of Castile on behalf of his sister failed to make any impression upon the king, and it was only the pressing danger from the Moors, which was removed in 1340 by the Castilian victory on the Salado, that induced him at last to consent to a compromise. The same desire to unite all the possessions of the Aragonese crown is apparent in his treatment of the king of Majorca, James II, the descendant of James I's younger son, who had received from his father the Balearic Islands with Roussillon and Cerdagne as a vassal kingdom. As James II showed inclination to evade his legal duties towards his suzerain, Pedro seized the first opportunity to pick a quarrel with him. In 1344 all the territories of the king of Majorca were declared to be united to Aragon, and, though James II made an obstinate resistance, he met with little support from his former subjects, and the hopeless struggle was ended by his death in 1348.

These high handed measures not unnaturally excited the misgivings of the nobles of Aragon, whose privileges were not likely to be very scrupulously respected by a prince with such an obvious sense of his own rights and duties. In 1347 chance gave them an eminent and capable leader. There was no law against female succession in Aragon, and there was the precedent of Queen Petronilla in its favour. On the other hand, there was a strong prejudice against it, and as a rule preference had been given to males, although further removed from the direct line. Pedro IV had an only daughter, Constance, and he was eager to secure the succession to her in preference to his brother James, who was popularly regarded as the heir to the throne. This unconcealed intention excited the indignation of James, who was already discontented at the harsh treatment of the king of Majorca. He had no difficulty in inducing most of the chief nobles, including his half-brothers, to form a "Union," which was also joined by several of the towns in their discontent at the projected settlement of the succession (1347). Pedro was taken by surprise and could only gain time by concessions. He promised to convocate annual meetings of the cortes, to choose his councillors with the approval of the estates, to revoke his will in favour of his daughter, and to recognize his brother as his heir. Soon after this agreement, which left the Union master of the situation, James died, and men were not slow in attributing his death to the machinations of the king. This event was of the greatest advantage to Pedro, as it deprived his opponents of their leader, and

from this moment the rebellion began to be split up by personal rivalries. The king and his advisers were not slow to avail themselves of the opportunity thus offered. The opposition was strongest in Aragon and Valencia, and Pedro succeeded in gaining over the Catalonians, who were always prone to act in isolation from the other provinces. With the troops thus acquired he met the army of the Union at Epila (1348) and won a complete victory. He followed up his success by destroying all the charters which gave any sanction to armed resistance to the crown, and especially the Privilege of Union of 1287. His elder half-brother Ferdinand, who had succeeded James as leader of the revolt and as heir apparent to the throne, fled to Castile, but the chief nobles were severely punished, and the power of the crown was raised to a height which it had never before attained.

Thus Aragon, following the tendencies of the age, became centralized under a powerful monarchy, and the forces of feudal disunion received a final check. But Pedro IV was far from establishing anything like a despotism. While destroying the Privilege of Union, he took a solemn oath to respect the political and personal liberties of his subjects, and enjoined the same oath upon his successors. At the same time he strengthened the powers of the justiciar, whose pre-eminence dates from this reign. The position of the king was immensely strengthened by the birth of a son, which destroyed the claims of his half-brothers. The later part of his reign was occupied with a war against Henry II of Castile, which has been referred to above, and with resistance to James III of Majorca, who made an unsuccessful effort to recover the territories of his father. Pedro concluded a second marriage with Sibilla, daughter of a Catalan knight, and her influence involved him in a quarrel with his eldest son, whom he attempted to deprive of the office of lieutenant-general, which custom assigned to the heir to the throne. But he found that the authority of the justiciar was now strong enough to restrain the crown as well as the nobles. Dominic de Cerda, who now held the office, pronounced that the infant was legally entitled to the dignity from which he had been ousted, and compelled the king to restore him. The brief reign of John I. (1387-1395) was mainly occupied with wars in Sicily and Sardinia. The expense which these involved, which was increased by the luxury of a magnificent court, excited the most lively discontent on the part of the cortes. The remonstrances of his subjects were resented by the king, but they were backed up by the authority of the justiciar, and John I. gave way so far as to banish the unpopular favourites from the court. On the king's death his daughters were passed over, and the crown was transferred to his brother Martin, who was occupied in restoring the Aragonese supremacy in Sicily. Under Martin a private war between the great families of Urrea and Luna was put down, and the dependence of the great nobles was more firmly secured. But the death in 1409 of the king's only son, Martin the younger, brought the kingdom face to face with the difficulty of a disputed succession. There were two male claimants,—the count of Urgel, a great-grandson of Alfonso IV, and the duke of Gandia, a grandson of James II. The former was the undoubted heir if the succession was absolutely limited to males, while the latter was advanced in years and could only bring forward the old contention of nearness to the royal stock. But, although precedent was in favour of the exclusion of females, there was no definite rule to prevent the succession of their male descendants. Of such claimants there were two,—Louis of Calabria, the son of John I's daughter Violante, and Ferdinand, infant of Castile, the son of Martin's sister Eleanor. Moreover,

and Carillo, archbishop of Toledo, both of whom had objects of their own to serve. In 1465 the rebellion broke out, and its first act was the formal deposition of Henry at Avila, after an absurd ceremony in which the king was represented by a puppet. The conspirators denounced the infanta Joanna as illegitimate, and offered the crown to Henry's brother Alfonso. In the course of the civil war which followed, Alfonso died (1468), and his partisans at once put forward the claims of his sister Isabella. But the infanta, who already displayed a wisdom and moderation beyond her years, refused to be involved in hostilities with her elder brother, and she succeeded in arranging a treaty by which she was recognized as Henry IV's heirress. The king himself struggled hard to evade these conditions, and after his death in 1474 Joanna's cause was espoused by her uncle, Alfonso V of Portugal. But Isabella succeeded in securing her accession to the throne, and her marriage with Ferdinand of Aragon, by paving the way for the union of the two kingdoms, begins a new period in which for the first time there is a real history of united Spain.

Isabella.

ARAGON
(1213-
1479)
Consti-
tution.

The kingdom of Aragon which we left in the reign of James the Conqueror (1213-1276), consisted of the three provinces of Aragon, Catalonia, and Valencia. Each province retained its own laws and institutions, and Valencia and Catalonia regarded with the keenest jealousy any attempt to govern them on the principles which prevailed in Aragon. The powers of the crown were far more limited than in the neighbouring kingdom of Castile. The great nobles, or *ricos hombres*, formed a small and exclusive class, whose privileges made them almost the equals of the monarch. All conquests had to be divided between them, and the king was forbidden to confer a fief or honour upon any person outside their ranks. They possessed and exercised the right of private war, and were entitled at will to renounce their allegiance to their sovereign. The smallness of their numbers made them much more united than the nobles of Castile, and proportionately more formidable. The difference between the two kingdoms was recognized by Ferdinand the Catholic with his usual acuteness when he said that "it was as difficult to divide the nobles of Aragon as it was to unite those of Castile." But the privileges of the nobles, great as they were, were not the only check upon the royal power. Each province had its own cortes, which possessed from a very early date the right of granting taxes and approving legislation. In Valencia and Catalonia the cortes consisted, as in Castile, of the ordinary three estates, but in Catalonia, where a maritime life had inspired the inhabitants with a passionate love of freedom, the commons enjoyed a predominance which was hardly to be paralleled in any other country in the Middle Ages. The cortes of Aragon, which were more important, and whose history has been more carefully elucidated, consisted of four estates or arms (*brazos*). Besides the great prelates and the *ricos hombres*, both of whom had the right of appearing by proxy, there was a separate chamber of smaller landholders. This contained the *infanzones*, or lesser tenants-in-chief, and the *caballeros* or knights, who were tenants of the greater barons but whose military rank gave them the right of personal attendance. The fourth chamber alone was representative, and consisted of the deputies of the towns. Their presence is first mentioned in 1133, thirty years before anything is heard of popular representation in Castile. Their numbers were naturally small, as the kingdom was of very limited extent, but it seems to have been early established that a town which had once sent deputies was permanently entitled to the privilege, and thus preserved them from having their rights tampered with by the crown as was

done in Castile. Besides their legislative and taxative functions, the Aragonese cortes were also a supreme court of justice, and in this capacity were presided over by the *justiciar*, an official whose unique powers have attracted the attention of all writers on Spanish history. In its origin the office had nothing very remarkable about it, and it is only the peculiar circumstances of the kingdom which forced it into such prominence. The justiciar was not at first entrusted with any political functions, but the difficulty of adjusting the relations between the king and the barons led to his being called in as mediator. By the 14th century he had become almost the supreme arbiter in all constitutional questions. To him the people could appeal against any infraction of their liberties, while the king regarded him as his chief councillor and as the most efficient barrier against armed rebellion, which was the only alternative method of settling disputes between his subjects and himself. As the justiciar thus became the pivot of the constitution, it was of great importance to secure that he should exercise his functions with firmness and impartiality. As the *ricos hombres* were exempted from corporal punishment, he was always chosen from the lesser nobles or knights, and was made responsible to the cortes under penalty of death. The dignity of the office was enhanced by the character of its successive holders, and the medieval history of Aragon abounds with instances of their fearless opposition to the crown and of their resolute resistance to despotism on the one hand and to anarchy on the other.

The glorious reign of James (I) the Conqueror was disturbed towards its close by quarrels which arose from his scheme of partitioning his conquests among his children. The death, however, of his youngest and favourite son put an end to these projects, and the most important of the provinces passed into the hands of Pedro Pedro III (1276-1285). Under Pedro and his son and successor Alfonso III (1285-1291), attention was almost wholly diverted from internal affairs to the conquest of Sicily. By his marriage with Constance, the daughter of Manfred, Pedro could put forward a claim to succeed to the Hohenstaufen in Naples and Sicily, but it is not probable that he would have been able to make any use of the claim if the Sicilian Vespers (1283) had not thrown that island into his hands. The result was a long series of wars with the Angevin rulers of Naples, but the hold upon Sicily was steadily retained. These wars had a notable influence upon Aragonese history, as they compelled the kings to purchase the support of their subjects by concessions which could only with great difficulty have been extorted from them. Thus in 1283 Pedro III granted the famous "General Privilege," the Magna Carta of Aragon. By this the crown formally laid down a number of rules to secure all classes against oppression. The General Privilege is quite as important a document as the English charter, it is even more full and precise, and its numerous confirmations show that it was as highly prized. It had the additional advantage of being issued to a people already possessed of institutions sufficiently developed to employ and defend the national liberties. But if Pedro's concessions were for the advantage of his country, his successor went to an extreme which was equally harmful. In 1287 Alfonso III signed the famous "Privilegio of Alfonso Union," by which his subjects were formally authorized to take up arms against their sovereign if he attempted to infringe their liberties. The right of revolt, while it is and must be the ultimate safeguard against oppression, becomes at once liable to abuse when it is formulated and discussed. The act of 1287 gave an unlimited licence to disorder, which could always disguise itself under the pretence of defending liberty. Until it was repealed

there was always a danger that the constitution would succumb, not to the tyrannical usurpations of the crown, but to the selfish interests of the nobles

James II On the death of Alfonso III the crown passed to his brother James II (1291-1327). The new king handed over Sicily to his younger brother Frederick, thus creating a separate dynasty in that island. In the hope of depressing the greater barons, James II strengthened the hands of the justiciar and sought to conciliate the clergy and citizens to the crown. By these steps he succeeded in avoiding any open conflict during his reign, and at the same time he sought to secure external unity by an edict which declared the three provinces of Aragon, Catalonia, and Valencia to be for ever indivisible (1319). But his successor, Alfonso IV (1327-1336), did not hesitate to break this edict, in spirit if not in letter, by carving out great fiefs for his second wife, Eleanor of Castile, and her children. By this measure he gave rise to the difficulties, and indirectly to the triumphs, of his son, Pedro IV (1336-1387). Pedro's reign is a great epoch in Aragonese history, as to him is due the arrest of the tendencies which threatened to divide and destroy the kingdom. He began by recalling his father's excessive grants to his stepmother and his half-brothers. The intervention of Alfonso XI of Castile on behalf of his sister failed to make any impression upon the king, and it was only the pressing danger from the Moors, which was removed in 1340 by the Castilian victory on the Salado, that induced him at last to consent to a compromise. The same desire to unite all the possessions of the Aragonese crown is apparent in his treatment of the king of Majorca, James II, the descendant of James I's younger son, who had received from his father the Balearic Islands with Roussillon and Cerdagne as a vassal kingdom. As James II showed inclination to evade his legal duties towards his suzerain, Pedro seized the first opportunity to pick a quarrel with him. In 1344 all the territories of the king of Majorca were declared to be united to Aragon, and, though James II made an obstinate resistance, he met with little support from his former subjects, and the hopeless struggle was ended by his death in 1348.

These high handed measures not unnaturally excited the misgivings of the nobles of Aragon, whose privileges were not likely to be very scrupulously respected by a prince with such an obvious sense of his own rights and duties. In 1347 chance gave them an eminent and capable leader. There was no law against female succession in Aragon, and there was the precedent of Queen Petronilla in its favour. On the other hand, there was a strong prejudice against it, and as a rule preference had been given to males, although further removed from the direct line. Pedro IV had an only daughter, Constance, and he was eager to secure the succession to her in preference to his brother James, who was popularly regarded as the heir to the throne. This unconcealed intention excited the indignation of James, who was already discontented at the harsh treatment of the king of Majorca. He had no difficulty in inducing most of the chief nobles, including his half-brothers, to form a "Union," which was also joined by several of the towns in their discontent at the projected settlement of the succession (1347). Pedro was taken by surprise and could only gain time by concessions. He promised to convoke annual meetings of the cortes, to choose his counsellors with the approval of the estates, to revoke his will in favour of his daughter, and to recognize his brother as his heir. Soon after this agreement, which left the Union master of the situation, James died, and men were not slow in attributing his death to the machinations of the king. This event was of the greatest advantage to Pedro, as it deprived his opponents of their leader, and

from this moment the rebellion began to be split up by personal rivalries. The king and his advisers were not slow to avail themselves of the opportunity thus offered. The opposition was strongest in Aragon and Valencia, and Pedro succeeded in gaining over the Catalonians, who were always prone to act in isolation from the other provinces. With the troops thus acquired he met the army of the Union at Epila (1348) and won a complete victory. He followed up his success by destroying all the charters which gave any sanction to armed resistance to the crown, and especially the Privilege of Union of 1287. His elder half-brother Ferdinand, who had succeeded James as leader of the revolt and as heir apparent to the throne, fled to Castile, but the chief nobles were severely punished, and the power of the crown was raised to a height which it had never before attained.

Thus Aragon, following the tendencies of the age, became centralized under a powerful monarchy, and the forces of feudal disunion received a final check. But Pedro IV was far from establishing anything like a despotism. While destroying the Privilege of Union, he took a solemn oath to respect the political and personal liberties of his subjects, and enjoined the same oath upon his successors. At the same time he strengthened the powers of the justiciar, whose pre-eminence dates from this reign. The position of the king was immensely strengthened by the birth of a son, which destroyed the claims of his half-brothers. The later part of his reign was occupied with a war against Henry II of Castile, which has been referred to above, and with resistance to James III of Majorca, who made an unsuccessful effort to recover the territories of his father. Pedro concluded a second marriage with Sibilla, daughter of a Catalan knight, and her influence involved him in a quarrel with his eldest son, whom he attempted to deprive of the office of lieutenant-general, which custom assigned to the heir to the throne. But he found that the authority of the justiciar was now strong enough to restrain the crown as well as the nobles. Dominic de Corda, who now held the office, pronounced that the infant was legally entitled to the dignity from which he had been ousted, and compelled the king to restore him. The brief reign of John I (1387-1395) was mainly occupied with wars in Sicily and Sardinia. The expense which these involved, which was increased by the luxury of a magnificent court, excited the most lively discontent on the part of the cortes. The remonstrances of his subjects were resented by the king, but they were backed up by the authority of the justiciar, and John I gave way so far as to banish the unpopular favourites from the court. On the king's death his daughters were passed over, and the crown was transferred to his brother Martin, who was occupied in restoring the Aragonese supremacy in Sicily. Under Martin a private war between the great families of Urrca and Luna was put down, and the dependence of the great nobles was more firmly secured. But the death in 1409 of the king's only son, Martin the younger, brought the kingdom face to face with the difficulty of a disputed succession. There were two male claimants,—the count of Urgel, a great-grandson of Alfonso IV, and the duke of Gandia, a grandson of James II. The former was the undoubted heir if the succession was absolutely limited to males, while the latter was advanced in years and could only bring forward the old contention of nearness to the royal stock. But, although precedent was in favour of the exclusion of females, there was no definite rule to prevent the succession of their male descendants. Of such claimants there were two,—Louis of Calabria, the son of John I's daughter Violante, and Ferdinand, infant of Castile, the son of Martin's sister Eleanor. Moreover,

Martin the younger had left an illegitimate son, Frederick, count of Luna, and if the question had arisen a century earlier, before the clergy had obtained so much power, it is probable that his claims would have been preferred. The question was still unsettled on the death of the elder Martin in 1410, with whom ended the male line of the counts of Barcelona. A prolonged civil war seemed inevitable, and for two years the kingdom endured the evils of an interregnum. If the dispute was to be settled by force of arms, the count of Urgel seemed likely to carry all before him, as he had the pretty unanimous support both of the Catalans and of the powerful family of Luna. But his followers, confident in their superiority, allowed themselves to indulge in acts of violence which alienated the more orderly part of the population. The justiciar, Juan de Cerda, who had acted with such impartial firmness in the reign of John I., succeeded in forming a patriotic party which determined to settle the dispute by a legal decision. Jealousy of the De Lunas gave to this party the support of the rival house of Urrea. They succeeded in procuring the appointment of a joint commission of nine members,—three from the cortes of each province. After a careful examination of all the claims, the commissioners decided, on what principle it is difficult to determine, in favour of the infant Ferdinand, who was then acting as regent of Castile for his nephew John II. (1412). As far as ability and merit went, the choice was probably the best that could have been made. By mingled firmness and concession Ferdinand succeeded in restoring order and unity to the kingdom and its dependencies. A revolt headed by the disappointed count of Urgel in the next year was suppressed, and its leader was punished with the confiscation of his territories and perpetual imprisonment.

Ferdinand
I

Thus the house of Trastámara succeeded in obtaining the crown of Aragon as well as that of Castile. Ferdinand I., the first king of the new dynasty, did not live long to wield the sceptre which he had so fortunately acquired. On his death in 1416 the crown passed to his son Alfonso V. (1416–1458). The new prince played little part in Aragonese history, as his attention was almost wholly absorbed in the affairs of Italy. To his inherited possessions of Sicily and Sardinia he added the kingdom of Naples after a seven years' contest with the Angevin claimant, René le Bon of Provence (1435–1442). From this time he never quitted his new kingdom, where his politic rule and his patronage of literature acquired for him the name of "The Magnanimous." During his absence the government of Aragon was entrusted to his brother John, as lieutenant-general. The arbitrary character of this prince, which is so clearly visible in his subsequent history, seems to have been foreseen by his subjects. In order to secure the justiciar from undue influence on the part of the crown, a law was made in 1442 that the office should be held for life, and that its occupant could only be dismissed by the king with the express approval of the cortes. In 1461 this provision was followed up by another law which directed that all complaints against the justiciar should be heard before a commission regularly chosen from the four estates.

Relations of
Aragon
and
Navarre

The history of John, both as regent for his brother and later as king in his own right, centres round the family quarrels which finally led to a formidable rebellion against him. His first wife was Blanche, widow of Martin of Sicily and heiress of Navarre. This little kingdom, which comprised territory on both sides of the Pyrenees, had been more closely connected with France than with Spain since its separation from Aragon on the death of Alfonso I. (1134). In the 13th century it was united to the French crown by the marriage of Jeanne of Navarre with

the French king, Philip IV, but it again became independent on the death of Louis X. in 1315. His daughter Jeanne was the undoubted heiress of Navarre, and, though she was kept out of her rights by her uncles, Philip V and Charles IV, she was allowed to succeed after their death. In 1329 she was crowned at Pamplona with her husband, Philip of Evreux. Her son, Charles the Bad (1349–1387), obtained an unenviable notoriety for the part which he played in French history during the troublous period of the English wars. His son, Charles III. (1387–1425), was a peace-loving prince, who devoted more attention to art and literature than to politics. The marriage of his daughter Blanche with John of Aragon brought the mountain kingdom once more into close connexion with the western peninsula. By her marriage contract, Navarre was to pass on her death to her children and not to her husband, but a later agreement enjoined her son, before assuming the sovereignty, to obtain "the goodwill and approbation of his father." When Blanche died in 1442, John seems to have considered that this later stipulation justified him in retaining the title of king of Navarre, though he entrusted the administration of the kingdom to his son, Charles of Viana. For some time no difficulty was made about this arrangement. But in 1447 John married a second wife, Joanna Henriquez, a descendant of the royal family of Castile, and a few years later he sent Joanna to share the government of Navarre with his son. This appointment, coupled with the arrogant conduct of his stepmother, was regarded as an insult by Charles of Viana, who was not slow to remember that by right he was entitled to the crown. The old parties of Navarre, the Beaumonts and Agramonts, seized the opportunity to renew their feuds,—the former espousing the cause of the prince, the latter that of the queen. Before long the dispute developed into civil war, and John marched into Navarre to assist his wife, who was besieged in Estella by her stepson. At Aybar the hostile forces met in open conflict, but the superior discipline of the royal troops gave them a complete victory, and Charles fell a prisoner into his father's hands (1452). The prince was released after a short imprisonment, but the reconciliation was only a hollow one. The birth of a son to Joanna Henriquez (1452), afterwards famous as Ferdinand the Catholic, was a serious blow to the interests of the elder son. The queen scarcely concealed her desire to secure the succession to her own child, and her influence over her husband was unbounded. Charles found that his defeat had given the supremacy in Navarre to the hostile party, and after a vain attempt to recover his power he went to Naples to appeal to his uncle Alfonso V. But his hopes in this quarter were destroyed by Alfonso's death in 1458. Of his possessions, Aragon, John I. Sicily, and Sardinia passed to his brother John II, while Naples, as a private acquisition of his own, was bequeathed to his natural son Ferdinand. The Neapolitan barons, dreading the gloomy and tyrannical character of their new ruler, offered to support Charles of Viana as a candidate for the throne, but he refused to oppose his cousin, and retired to Sicily, where he spent the next two years in seclusion. In 1460 he was induced to return by the solicitations of his father, who seems to have been disquieted by the popularity which the prince had obtained among the Sicilians. The intrigues of Joanna were not long in exciting the old mistrust between father and son, and her hostility towards Charles was increased by his attempts to obtain the hand of Isabella of Castile, whom she had already fixed upon as a suitable bride for her own son Ferdinand. In 1461 Charles was induced to meet his father at Lerida, and was at once imprisoned. When asked about the cause of this arbitrary proceeding, John

only replied with obscure hints at a conspiracy. But his subjects were not prepared to acquiesce in this unnatural treatment of a prince whom they had learned to love and whom they regarded as their future ruler. The Catalans, always easily moved, rose in arms and marched upon Lerida, and it was only by a hasty retreat that John was able to escape with his court to Saragossa. But the revolt speedily spread from Catalonia to the other provinces, and even to Sicily and Sardinia, while it found supporters in the king of Castile and in the faction of the Beaumonts in Navarre. Surrounded by enemies, John II found it necessary to yield. He not only released his son, professing that he did so at his wife's request, but appointed him lieutenant-general of Catalonia and promised not to enter that province without the permission of the cortes. But no sooner had Charles of Viana regained his liberty than he died, on September 23, 1461, and the circumstances led ready credence to be given to the suspicion that he had been poisoned during his captivity.

The crown of Navarre now devolved by right upon Charles's elder sister Blanche, who had been married to and afterwards repudiated by Henry IV of Castile. But she had incurred her father's enmity by the support which she had given to her brother, and John II was not unwilling to curry favour with France by securing Navarre to his second daughter Eleanor of Foix, whose son Gaston had married a sister of Louis XI. The unfortunate Blanche was committed to the guardianship of her younger sister, and after two years of imprisonment in the castle of Orthez she died of poison. But Eleanor reaped little advantage from the crime which all historians impute to her. Her father retained the crown of Navarre till his death, and she only survived him a few weeks. She was succeeded by her grandson Francis Phœbus, but he only lived for four years, and his sister and heiress Catherine brought the crown of Navarre by her marriage to the French house of D'Albret, from which it was wrested by Ferdinand the Catholic in 1512. This third union with Aragon proved permanent, although the district north of the Pyrenees was subsequently annexed to France.

Meanwhile the troubles of John II were by no means removed by his son's death. In Aragon the young Ferdinand was acknowledged as heir, and was then sent with his mother to Catalonia to receive the oath of allegiance from that province. But the Catalans rose again in rebellion, and besieged Joanna and her son in the fortress of Gerona. As John II was unable to advance through the revolted province to his wife's relief, he purchased the assistance of Louis XI by a promise of 300,000 gold crowns, as security for which he pledged the counties of Roussillon and Cerdagne (1462). The Catalans replied to this alliance by throwing off their allegiance to John and proclaiming a republic. As, however, Gerona was relieved by the French, and the royal troops succeeded in reducing several of the chief towns, they determined to appeal for foreign aid. The crown was offered first to Henry IV of Castile and then to the constable of Portugal, who was descended from the old counts of Barcelona. On the death of the latter in 1466 the rebels turned to the traditional rivals of the house of Aragon, and offered the crown to René le Bon, the head of the Angevin house. René, whose life had been spent in putting forward claims which he had never been able to enforce, accepted the offer and sent his chivalrous son John of Calabria to assist the Catalans (1467). John II's fortunes were now at their nadir. He had lost his eyesight, and the death of his wife in 1468 deprived him of the companion and adviser who had for years directed and inspired his policy. John of Calabria, whose enterprise was secretly encouraged by the treacherous king of France, was steadily regaining

much of the ground which had been lost by the Catalans before his arrival. But the old king, whose sight was restored by a surgical operation, fought on with a dogged obstinacy worthy of a better cause. The death of the duke of Calabria in 1469 deprived his opponents of their leader, and from this moment their ultimate defeat was inevitable. The fall of Barcelona (1472) completed the reduction of Catalonia. But John did not venture to abuse the victory which he had so hardly won. He granted a general amnesty, and took a solemn oath to respect the constitution and liberties of the conquered province. The only notable event of the remaining years of John II's reign was an attempt to recover Roussillon and Cerdagne. But Louis XI kept a firm hold by arms upon the provinces which his diplomacy had won, and they were only restored to Aragon in 1493 when Charles VIII ceded them to Ferdinand the Catholic. In 1479 the death of John II, at the ripe age of eighty-two, transferred the crown to his son Ferdinand, who ten years before had concluded his marriage with Isabella of Castile.

Literature—Lafuente, *Historia General de España*, Ortiz, *Compendio General de la Historia de España*, Mariann, *Historia General de España*, Lombko, Schafer, and Schürmacher, *Geschichte von Spanien* (down to 1295), Dory, *Histoire des Musulmans d'Espagne* (to 1110), Desormeau, *Abregé Chronologique de l'Histoire d'Espagne*. For the constitutional history the chief books of reference are—for Castile, Marina, *Teoria de las Cortes*, and Sempere, *Histoire des Cortes d'Espagne*, and for Aragon, Blancas, *Commentarii Rerum Aragonensium*, but a fair summary of their conclusions may be found in chapter iv of Hallam's *Middle Ages* and in the introduction to Prescott's *Ferdinand and Isabella*. The history of the Castilian cortes has been recently elucidated by Don Manuel Colmeiro in his *Cortes de los Antiguos Reinos de Leon y de Castilla* (Madrid, 1883). The chief medieval chroniclers may be found, though not well edited, in Florez, *España Sagrada*, and Schott, *Hispania Illustrata*. (R. L.)

SECTION IV—MODERN HISTORY

The history of Spain as a united state dates from the union of Castile and Aragon by the marriage of Isabella and Ferdinand. The marriage took place in 1469, before the accession of either sovereign. In 1474 the crown of Castile was claimed by Isabella on the death of her brother Henry IV, whose daughter Joanna was universally believed to be illegitimate. It was contended by the partisans of Ferdinand that female succession was prohibited in Castile, and that he was entitled to the crown as the nearest male heir after his father. Ultimately the question was settled in Isabella's favour, and she obtained the most important rights of sovereignty, though the government was carried on in their joint names. It is possible that Ferdinand would have refused to accept this arrangement, if concerted action had not been necessary to oppose the party which espoused the cause of Joanna. A number of the Castilian nobles, headed by the marquis of Villena, dreaded the danger to the privileges of their order that might arise from the establishment of a strong government. They found an ally in Alfonso V of Portugal, who was Joanna's uncle by the mother's side, and who cherished the design of obtaining the Castilian throne by a marriage with his niece. In 1476 the confederates were routed in the battle of Toro, and Alfonso departed to France with the chimerical plan of seeking assistance from Louis XI. The treaty of St Jean de Luz between France and Castile in 1478 ruined these hopes, and in the next year Alfonso was compelled, by the treaty of Lisbon, to abandon the cause of his niece. This terminated the war of succession in Castile, and Joanna, known from her reputed father as La Beltraneja, retired into a convent. A few months before the treaty of Lisbon the death of John II (January 20, 1479) gave to Ferdinand the succession to Aragon, Sicily, and Sardinia. Navarre, which had been brought

the Catholic.

Ferdinand and Isabella

to John II by his first wife, passed to his daughter by that marriage, Eleanor, countess of Foix. Two provinces of the Aragonese crown, Roussillon and Cerdagne, had been pledged by John to Louis XI of France, and were still retained by that monarch. The union of Castile and Aragon effected in 1479 was merely a personal union. Each province retained its own institutions and its own laws, and each would have resented the idea of absorption in the other.

Adminis-
trative
reforms.

The first care of the two sovereigns was to reform the system of government, especially in Castile, where the recent civil wars had given rise to serious disorders. One of their chief objects was to depress the nobles, whose privileges, acquired during the long struggle against the Moors, were inconsistent with a strong centralized government. In accordance with true policy and with the spirit of the age Ferdinand and Isabella sought to counterbalance the nobles by relying upon the burgher class. The *Santa Hermandad*, or Holy Brotherhood, which was organized in 1476, was a popular confederation of the whole kingdom for police and judicial purposes. Its affairs were managed by local courts,—from which appeals could be made to a supreme tribunal,—and by a general junta composed of deputies from all cities, which was convened once a year. A body of 2000 cavalry was at the disposal of the association, and a special code of laws for its guidance was compiled in 1485. The institution was completely successful in maintaining order and in diminishing the independence of the local jurisdiction of the great nobles. About the same time the lavish grants from the royal domain, which had enriched the nobles at the expense of the crown, were revoked, the central judicial courts were made more efficient by the introduction of trained lawyers, and steps were taken to codify the numerous laws that had been made since the *Siete Partidas* of Alfonso X. The grandmasterships of the great orders of St. Iago, Calatrava, and Alcántara, which conferred powers too great to be entrusted to a subject, were on successive vacancies secured to the crown. Trade was encouraged by protective measures, by the breaking down of the barriers between Castile and Aragon, by a strict reform of the currency, and by the commutation for a fixed impost of the detested *alcavala*, a tax of one tenth upon all sales and transfers of property.

The increased prosperity of the country is well illustrated by the steady rise of the revenue. "In 1474, the year of Isabella's accession, the ordinary rents of the Castilian crown amounted to 885,000 reals, in 1477 to 2,390,078, in 1482, after the resumption of the royal grants, to 12,711,591, and finally, in 1504, when the acquisition of Granada and the domestic tranquillity of the kingdom had encouraged the free expansion of all its resources, to 26,283,334, or thirty times the amount received at her accession. All this was derived from the customary established taxes, without the imposition of a single new one" (Prescott, ii 575). No attack was made upon the liberties of the subjects, the cortes of Castile were frequently convened, the same towns were called upon to send deputies, and the only innovation was the frequent neglect to summon the nobles. The numerous *pragmaticas*, or royal ordinances, were mostly limited to administrative matters or to the interpretation of the law. The credit for the domestic administration rests mainly with Isabella. Ferdinand busied himself more with military and diplomatic affairs, and comparatively few innovations were made in Aragon. The *Hermandad* was introduced, and in some other points the example of Castile was followed. But the advanced constitutional liberties of Aragon were uncongenial to Ferdinand. He summoned the cortes as rarely as possible, and when that assembly

met he spared no pains to influence its composition and its decisions. The centralizing tendencies of the reign were carried still further in both provinces in the later period when Ximenes, who became archbishop of Toledo in 1495, exercised the chief influence. Five councils were entrusted with the administration of affairs—the "royal council," the chief court of justice, the "council of the supreme" for ecclesiastical business, the "council of the orders" for the great military fraternities, the "council of Aragon" for the management of that kingdom and of Naples, and the "council of the Indies" for the great discoveries of Columbus and his companions.

The political unity of Spain was to be based upon its religious unity. Both Ferdinand and Isabella were imbued with that stern spirit of orthodoxy with which the Spaniards were inspired by their long crusade against the infidel. No institution of their reign was so important as the Inquisition, which was authorized by a bull of Sixtus IV in 1478, and constituted for the two kingdoms in 1483 under the presidency of Torquemada. Its extension to Aragon was bitterly protested against by the liberty-loving people, but was forced upon them by the iron will of Ferdinand. The activity of the Holy Office was at first directed against the Jews, whose obstinate adherence to their faith in spite of persecution was punished by an edict for their expulsion in 1492. Their departure deprived Spain of many industrious inhabitants, but its importance has been much exaggerated by authors who have failed to notice that it was followed, not by the decline of Spain, but by the period of its greatest prosperity. In spite of their orthodoxy, however, Ferdinand and Isabella were by no means slavish adherents of the papacy. The claim of the popes to appoint to important benefices was strenuously resisted, and the chief control of ecclesiastical affairs was successfully vindicated for the crown.

The steady extension of the royal power in Spain was due in no small degree, as Machiavelli has pointed out, to the constant succession of enterprises in which the attention of the nobles was absorbed. These enterprises may be summarized under three heads—(1) the union of the Peninsula, (2) the extension of colonial empire, and (3) the acquisition of foreign territories.

(1) Under the first head the most important achievement was the final extinction of the Moorish power in Spain. The war which began in 1481 was carried on in a desultory manner for ten years, and was completed in 1492 by the conquest of Granada. The Moors, who had fought with the courage of despair, received very lenient terms from their conquerors. They were secured in the free exercise of their religion, and were allowed to retain their own laws, customs, and language. In some points, such as the trade with Africa, they obtained privileges which were not even shared by the Castilians. But the spirit of proselytism was too strong in Spain to allow this treaty to be observed. The measures taken by Ximenes to bring about the conversion of the Moors provoked a revolt in 1500, which was put down with great severity. They were compelled to choose between conversion or banishment, and, although most of them accepted the former alternative, the Moriscos, as they were now called, found themselves henceforward in the hopeless position of a proscribed and hated minority. In 1493 Ferdinand extorted from the fears and hopes of Charles VIII of France the restoration of Roussillon and Cerdagne by the treaty of Barcelona. In 1512, after Isabella's death, he annexed Navarre. The whole Peninsula was now united, with the exception of Portugal, and steps had been taken for the acquisition of that kingdom by marriage. Isabella, Ferdinand's eldest daughter, was married to Alfonso, the son and heir of

John II of Portugal After the death of that prince his widow married Emanuel, who succeeded to the Portuguese crown in 1495 Isabella herself died in giving birth to a son, but the connexion was still maintained by the marriage of Emanuel to her younger sister Mary The fruits of this persistent policy were not reaped, however, till the reign of Philip II

Colonial empire. (2) Maritime discovery was the task of the age, a task forced upon it by the Turkish occupation of the Levant, which had closed the old commercial routes to the East The foremost pioneers in the work were the Portuguese and Spaniards, whose efforts brought them into rivalry with each other The treaty of Lisbon in 1479 secured the western coast of Africa to Portugal, but enabled Spain to complete the annexation of the Canaries The Spaniards now turned further westwards, and a wholly new problem was created by Columbus's discovery of the West Indies in 1492 His voyage had been undertaken under the patronage of Isabella, and the new territories were regarded as pertaining to Castile To solve any difficulties that might arise, a bull was obtained from Alexander VI. in 1493, which granted to Spain all discoveries west of an imaginary line drawn 100 leagues to the west of the Azores and the Cape Verde Islands. As this arrangement excited Portuguese discontent, it was modified by a treaty at Tordesillas in 1494, which removed the boundary line to 370 leagues west of the Cape Verde Islands This modification had important results for the Portuguese, as giving them their subsequent claim to Brazil In the meanwhile Spain redoubled its exertions In 1498 Columbus landed on the continent of South America, and in a few years the whole western coast was explored by subsequent adventurers In 1512 Ponce de Leon discovered Florida, and in the next year Balboa crossed the Isthmus of Darien and gazed for the first time upon the Pacific No exertions were spared by the Government to encourage settlement in its new territories, but the regulations of colonial trade, and especially the provision that it should pass through the single port of Seville, were conceived in a narrow and selfish spirit which prevented the full development of their resources

Acquisition of Naples (3) The foreign affairs of the reign, which were almost wholly connected with Italy, were conducted by Ferdinand on behalf of Aragon, just as the extension of the colonies was directed for the benefit of Castile Charles VIII's invasion of Naples, which was ruled by an illegitimate branch of the house of Aragon, was undertaken in the full belief that the support or at least the neutrality of Spain was secured by the treaty of Barcelona. But Ferdinand, jealous of the rapid success of the French, seized the first pretext to disregard the treaty, and became a member of the league which was formed at Venice in 1495 against Charles His troops, under the famous Gonsalvo de Cordova, took a prominent part in restoring Ferdinand II. to the Neapolitan throne With the accession of Louis XII. came a great change in Ferdinand's policy, and he determined to advance the claim to Naples which he himself possessed as the legitimate head of the Aragonese house By the treaty of Granada in 1500 Naples was to be divided between France and Spain, and the reigning king Frederick could make no resistance to such overwhelming forces But a quarrel naturally arose about the terms of the partition, and by 1504 Gonsalvo de Cordova succeeded in expelling the French from Naples, which was henceforth annexed to the crown of Aragon

Death of Isabella. In 1504 the unity of Spain was interrupted for a time by the death of Isabella. The successive deaths of the infant John (1497), of Isabella of Portugal (1498), and of her infant son Miguel (1500) had left the succession in Castile to the second daughter, Joanna, she was

married to the archduke Philip, son of Maximilian I., and ruler, through his mother Mary of Burgundy, of the Netherlands and Franche Comté. Unfortunately Joanna, who was the mother of two sons, Charles and Ferdinand, had already given signs of that insanity which was to cloud the whole of her subsequent career Philip, who had visited Spain in 1502, had then excited the distrust of his wife's parents, and Isabella by her will left the regency in Castile to her husband until the majority of their grandson Charles But Ferdinand, in spite of his brilliant successes, was not popular among the Castilian nobles, who seized the opportunity to support the more natural claims of Philip to govern on behalf of his wife Ferdinand showed his disgust by actions which threatened to undo all the previous objects of his policy He concluded a treaty with Louis XII in 1505, by which he undertook to marry the French king's niece, Germaine de Foix To her Louis resigned his claims upon Naples, but in case of her death without issue his share in the kingdom by the treaty of Granada was to revert to France Thus Ferdinand was willing to gratify his spite and to perpetuate the division between Aragon and Castile, under the penalty of forfeiting his recent conquests in Italy His second marriage was concluded in March 1506, and two months later he resigned the regency in Castile to Philip, and soon afterwards sailed to Naples

But the division of the Peninsula was not destined to last long On September 25 Philip died at the age of twenty-eight, and the devotion of Ximenes secured the restoration of the regency to Ferdinand Joanna, who had been devotedly attached to her husband, lost all semblance of reason after his death, and made no attempt to exercise any influence over the conduct of affairs The remaining part of Ferdinand's reign is uneventful in the history of Spain The government was carried on on the same system, but with more avowed absolutism, as during the lifetime of Isabella. Ximenes, whose energies found insufficient occupation in the compilation of his Polyglott Bible and in the foundation of the university of Alcalá de Henares, fitted out and headed an expedition to Oran in 1509, which resulted in extensive but short-lived conquests in northern Africa Ferdinand threw himself with more energy than ever into the current of European politics By joining the league of Cambray he wrested from Venice five important towns in Apulia which had been pawned to the republic by Ferdinand II As a member of the Holy League against France he succeeded in conquering Navarro in 1512 Navarre had passed to the French family of Albret by the marriage of Catharine de Foix with Jean d'Albret, and it was the close connexion with France which gave Ferdinand a pretext for its invasion In 1515 his new conquest was formally incorporated with the kingdom of Castile This was Ferdinand's last success, and he died on January 23, 1516 His will recognized Joanna as his heiress in Aragon, and his grandson Charles as the regent in both kingdoms Until his arrival, the administration of Castile was entrusted to Cardinal Ximenes and that of Aragon to his own natural son, the archbishop of Saragossa

With the death of Ferdinand begins the period of uninterrupted Hapsburg rule in Spain, which lasted for nearly two centuries In the course of this period the monarchy obtained absolute authority, and Spain, after rising for a time to be the foremost state in Europe, sank to the position of a second rate power, from which it has never since emerged At first the condition of affairs was by no means promising for the crown The unity of Spain, which had advanced with such rapid strides after the marriage of Ferdinand and Isabella, had been seriously shaken by the selfish policy pursued by the king since his

Death of Ferdinand.

(1516-1700)

wife's death. Aragon and Castile were distinct kingdoms, and the former was again divided into the three provinces of Aragon, Catalonia, and Valencia, each of which had its own cortes, its own privileges, and the most warmly-cherished traditions of independence. Classes were everywhere divided against each other, and within each class jealousies and quarrels were frequent. The foreign possessions of the two crowns were a source of weakness rather than of strength. France stood ready at the earliest opportunity to contest the possession of Navarre with Castile, and that of Naples with Aragon.

Charles
I
(emperor
Charles
V.)

The difficulties of domestic government were increased by the fact that the prospective ruler was a youthful foreigner, who had never visited Spain, and who was completely ignorant of the customs and even of the language of the country. Charles had been born and educated in the Netherlands, of which he had been nominal ruler ever since the death of his father in 1506. All his friends and advisers were Flemings, who cared nothing for Spanish interests and had already acquired an evil reputation for selfish greed. The first symptom of discontent in Spain was excited by Charles's demand to be recognized as king, in utter disregard of his unfortunate mother. In Aragon the demand was unhesitatingly refused, but in Castile the vigorous measures of Ximenes secured Charles's proclamation. The regent, however, had great difficulties to face. The nobles, delighted to be rid of the strong government of Ferdinand, wished to utilize the opportunity to regain the privileges and independence they had lost. In this crisis the loyal devotion of Ximenes saved the monarchy. Throwing himself upon the support of the citizen class, he organized a militia which overawed the nobles and maintained order. A French invasion of Navarre was repulsed, and to avoid any danger from the discontent of the inhabitants all the fortresses of the province, with the single exception of Pamplona, were dismantled. These distinguished services were rewarded with more than royal ingratitude by Charles, who came to Spain in 1517, and who allowed the aged cardinal to die on November 8 without even granting him an interview.

The young king soon felt the loss of so able and experienced an adviser. His Flemish ministers, with Chièvres at their head, regarded Spain as a rich booty to be plundered at will. The Castilians, the proudest nation in Europe, found all the places of honour and profit seized by greedy foreigners. The cortes had shown their loyalty by acknowledging Charles as joint-king with his mother and by granting him an unprecedented service of 600,000 ducats. But they had accompanied their grants with eighty-eight significant demands, which the young king accepted but made no pretence of fulfilling. In Aragon and Catalonia more difficulty was experienced. Nearly two years were wasted in obtaining the recognition of the royal title, and no supplies were forthcoming. Valencia was not visited at all, and the attempt to induce the people to do homage to a viceroy was a failure. A civil war broke out in the province between the privileged nobles and a *germandada*, or brotherhood, of the burgher class. The Government exasperated parties by supporting each in turn, but ultimately threw in its lot with the nobles.

Meanwhile the death of Maximilian had given Charles the succession to the considerable Hapsburg territories in Germany, and in 1519 the German electors had chosen him to be king of the Romans. He was now the first prince in Europe, and it was necessary for him to leave Spain to look after his interests in Germany and to cement there alliances which he needed against the inevitable hostility of France. But his elevation by no means increased his popularity in Castile. The Castilians had

already plenty of grounds for complaint in the rapacity of the Flemings and in Charles's failure to perform his promises to the cortes. But these were as nothing compared with the prospect that Castile might no longer be the primary state of their king, and that their revenues might be employed in the attainment of objects in which they had not the slightest interest. While opinions were thus excited, Charles, who had been reduced to great straits by his military preparations and his promises to the German electors, summoned the cortes to meet at Santiago (Compostella) in Galicia, and thence transferred them to Coruña in order to embark as soon as he had obtained the supplies he needed. The place of meeting was carefully chosen so as to isolate the assembly and to expose it to royal influence or intimidation. The lead of the opposition was taken by Toledo, which refused to send its two deputies, as being too favourable to the crown, but sent other representatives to remonstrate with Charles and to encourage the other cities. They were driven from Coruña, and the deputies of Salamanca were excluded from the cortes. By these and similar means the desired grant was extorted. Charles hastened to quit Spain with the first favourable wind, leaving Adrian of Utrecht as regent in Castile, and two native nobles in Aragon and Catalonia. His departure was really necessary for his other interests, but it must have seemed reckless to the Spaniards at a time when Valencia was in the flames of civil war and Castile was on the verge of rebellion. Before starting he had ordered the removal of the magistrates of Toledo, and had sent a new governor to reduce the city to obedience. The citizens, headed by a young noble, Juan de Padilla, resisted this order and raised the standard of insurrection. Other cities hastened to join the movement, and a central committee, known as the "Holy Junta," established itself at Avila. The unfortunate regent, a churchman of distinguished piety and gentle character, found himself face to face with difficulties that would have taxed all the resources of Ximenes. His attempt to reduce Segovia by arms was a lamentable failure, and he had to confess his utter defeat by disbanding his forces. The nobles, alienated by the appointment of a foreigner to the regency, made no attempt to check a movement against a Government they detested. The insurgents had matters their own way, and Padilla, advancing to Tordesillas, made himself master of the person of Joanna, in whose name it was intended to conduct the government. But this move was less advantageous than it at first appeared. Joanna refused to transact any business or to sign any document, and this public proof of her incapacity served to justify Charles's contention that he was the only possible ruler. The Castilians were not prepared to get rid of the monarchy, so that it was necessary for the rebels to consider the possibility of coming to terms with Charles. The "Holy Junta," which had moved from Avila to Tordesillas, drew up a series of demands, which, if acceded to, would have established a constitutional monarchy in Spain. But their envoys to Germany found it impossible even to secure an audience from the king, and meanwhile the failure of the insurrection was decided. The very ease with which the rebels had triumphed proved an evil, because it encouraged internal dissensions which opposition might have healed. Especially Burgos showed its jealousy of the leading position which had been assumed by Toledo. Class differences, the bane of every country in the Middle Ages, supplied the final stumbling block. Many of the demands of the communes were diametrically opposed to the interests of the nobles, whose eyes were at last opened to the danger of their attitude of neutrality. Their chief grievance had been removed by Charles's appointment of

Rising of
the com-
munes.

the admiral and constable of Castile as joint-regents with Adrian. An army was raised, and on the field of Villalar the forces of the communes were utterly defeated (April 23, 1522). Padilla, who had shown more enthusiasm than ability, was executed, and one city after another was reduced to submission. A portion of the victorious army was sent to the assistance of the nobles in Valencia, where the *germandade* was at last crushed. The return of Charles to Spain in June 1522 completed the triumph of the monarchy. In 1523 he convened the Castilian cortes, and compelled them to grant supplies before presenting their petitions for redress, thus establishing a precedent which was conclusive for the future.

Charles's reign belongs to the history of Europe rather than to that of Spain, and has been sufficiently treated elsewhere (see CHARLES V). His enormous inheritance was increased by the successes of Cortes in Mexico and of Pizarro in Peru, by his own annexation of the Milanese, and by his conquests in northern Africa. In the government of this vast empire Spain played an important but on the whole a subordinate part. Its soldiers and its subsidies were Charles's most effective weapons, and to render them more readily available it was necessary to depress still further the liberties of the country. The independence of the towns had been crushed at Villalar, but only by the intervention of the nobles, and these had now to pay the penalty of their selfish loyalty. In 1538, after Charles had for a time concluded his struggle with France by the truce of Nice, he proposed to raise supplies in Castile by an excise upon commodities. The nobles objected on the ground of their exemption from taxation, and the emperor had to give way. But he took his revenge by excluding them altogether from the cortes, which henceforth consisted only of thirty-six deputies from eighteen towns, a body that was powerless to oppose the wishes of the crown.

The vast enterprises in which Charles was involved exhausted his energies, and the failure of his policy in Germany reduced him to despair. In 1555-56 he resigned all his dignities, and ended his life in 1558 in retirement at Yuste. From this time the house of Hapsburg is divided into the two branches of Spain and Austria. Charles's brother Ferdinand became king of the Romans and obtained the German territories of the family, to which he had added the crowns of Bohemia and Hungary. Philip II, Charles's only legitimate son, succeeded to the Spanish and Burgundian inheritance, with the addition of Milan. Philip II, like his father, played a great part in European history (see PHILIP II), but with this important difference that Castile was definitely the central point of his monarchy, and that his policy was absolutely directed by Spanish interests. In character and education he was a Spaniard of the Spaniards, and after 1559 he never quitted Spain. He gave the country a capital, which it had never yet possessed, by fixing his residence at Madrid. Castile, under the direct supervision of the king, was subjected to the most crushing despotism. Aragon, Catalonia, and Valencia were governed as mere provinces, in the same manner as Milan, Naples, and Sicily. The continuance of the old divisions of the country, while it lessened its strength, was an immense advantage to the royal power. It was easy for the king to employ the forces of one province to crush the liberties of the others. And Philip possessed a formidable weapon in the Inquisition, which he did not scruple to use for secular purposes. Political independence was crushed with the same relentless severity as religious dissent. Hitherto Aragon had preserved its mediæval privileges almost intact. The king was not entitled to the allegiance of the province until he had solemnly sworn to observe its "*fueros*." For the decisions of the cortes unanimity was required, so

that each deputy had a practical right of veto. The authority of the justiciar rivalled that of the crown. It was natural that Philip should seize the first opportunity of attacking institutions which could thwart his will. In 1590 Antonio Perez (see PEREZ), a minister who had incurred the king's displeasure, fled to Aragon and appealed to its *fueros* for protection. Philip had him brought before the Inquisition, and when the people rose in defence of their liberties they were crushed by troops from Castile. The justiciar was put to death, and his successors became nominees of the crown. The cortes were assembled in 1591 at Tarragona, and compelled to abolish the most obnoxious *fueros*. Their control over the judicial administration was abrogated, and the necessity of unanimity was only retained in certain specified cases, notably the granting of supplies. To avoid any danger from the few privileges that were left, a citadel was built in Saragossa for the reception of a royal garrison. The creation of a regular standing army completed the edifice of absolutism, while the militia which had been established by Ximenes was retained and extended for the suppression of local disorders.

Philip's internal administration was everywhere successful in obtaining the objects which he set before himself. A rising of the Moors in the Alpujarras was crushed by the military ability of his famous half-brother, Don John of Austria. In 1580 a claim to the crown of Portugal, which Philip derived from his mother, was successfully asserted. Thus the unity of the Peninsula was at last completed, while the colonial territories of Spain were immensely extended. Unfortunately, no attempt was made to conciliate the Portuguese to their new ruler. The kingdom was treated as a conquered province, all who had resisted the Spanish invasion were punished as traitors, the native nobles were excluded from all share in the government, which was entrusted solely to Spaniards, the commerce of the country was ruined by provisions which conferred a practical monopoly upon Spain. The result of this short-sighted policy was that the Portuguese stifled their discontent, and eagerly awaited the first opening for the recovery of their independence.

Outside Spain Philip's policy proved a complete failure. His religious intolerance excited the revolt of the Netherlands, which ended in the loss of the seven northern provinces. His grand schemes against England were utterly ruined by the destruction of the Spanish Armada. And, finally, his endeavour to establish a preponderant Spanish influence over France was foiled by the accession and triumph of Henry IV. The treaty of Vervins, by which he acknowledged his humiliating defeat, was almost the last act of Philip II's reign, which ended with his death on September 13, 1598.

Philip II left to his son and successor, Philip III, an empire which was nominally undiminished, as the independence of the United Provinces had never been recognized, and the war for their reduction was still going on. But the unwieldy mass was suffering from internal exhaustion. The resources of Spain and the New World had been squandered in the prosecution of schemes of ambition which had ended in failure. The attention of the people had been distracted from peaceful industry to the unprofitable occupation of war. The soldiery of Spain, once reckoned invincible, had lost their prestige in the marshes of Holland. The enormous taxes, from which nobles and clergy were exempted, fell with ruinous severity upon the productive classes. Castile had suffered most, because it was most completely subject. The provinces which retained their liberties longest were more prosperous, even though they had no share in the riches that were poured into Castile from the western colonies. But they,

too, had suffered from the king's reckless ambition and from an economic policy which followed the most glaring errors of the Middle Ages. Every other consideration had been sacrificed to the accumulation of specie, with the result that prices were forced up to an abnormal height, while the wealth of the country bore no proportion to the currency. The nobles were carefully excluded from all political affairs and ceased to take the slightest interest in the administration. When this exclusion came to an end after Philip II's death, they appear as mere courtiers, rivalling each other in the extravagance of their expenditure, but contributing nothing to the efficiency of the state. The government had been centralized by successive kings, but it was carried on without either wisdom or impartiality. The administration of justice was venal and incompetent. The people had been deprived of their liberties, but they failed to receive compensation in increased order and security. Spain had to pay dearly for its short period of glory. Its rapid decline in the 17th century was the inevitable penalty for the faults and errors of the 16th.

Philip
III

"God," said Philip II, "who has been gracious in giving me so many states, has not given me an heir capable of governing them." His successor was the natural product of his father's system: the exhaustion of Spain was inevitably accompanied by the degeneracy of its rulers. Philip III, who was twenty-one years old at his accession, had been brought up among priests and women, and showed all the defects of his education. Spanish writers are never weary of dilating upon his piety and his devotion. The cares of government he left entirely to his favourite, the duke of Lerma, while he contented himself with the performance of religious duties and the ceremonies of a stately court. The change of rulers was significantly marked in a quarrel with the province of Biscay, which still retained its ancient privileges intact. An attempt was made in 1601 to impose new duties by a royal ordinance, the Biscayan deputies protested vigorously against this encroachment upon their liberties, and openly threatened to seek another ruler. Philip III hastened to avert the storm by withdrawing the obnoxious ordinance. Thus the policy of centralization was abandoned, and the tendencies to division and isolation were confirmed.

The
Moors
expelled
from
Spain.

The piety of Philip III, which was as disastrous to Spain as the more masculine bigotry of his predecessors, found characteristic expression in the persecution of the Moriscos. Ever since the suppression of their first revolt in 1502,—a revolt which was provoked by the breach of the compact made on the fall of Granada,—the conquered Moors had been cruelly oppressed. Charles V renewed the edict of 1502 in 1526, and the overt profession of Mohammedanism was extinguished in Spain. But in secret they continued to cherish the faith of their ancestors, and this was enough to exasperate a monarch who preferred to have no subjects at all rather than to rule over heretics. An edict of Philip II in 1566 forbade them to speak or write in Arabic, and ordered them to renounce all their traditional habits and ceremonies. Futile remonstrances were followed by a desperate rising, which was quelled in 1570. The most obstinate of the rebels were exiled to Africa, but most of them sullenly submitted. Philip III determined to prove his zeal for orthodoxy by completing the work which his father had left unfinished. In 1609 all the Moriscos were ordered to depart from the Peninsula within three days, and the penalty of death was decreed against all who failed to obey, and against any Christians who should shelter the recalcitrant. The edict was obeyed, but it was the ruin of Spain. The Moriscos were the backbone of the industrial population, not only in trade and manufactures, but also in agriculture. The haughty and indolent

Spaniards had willingly left what they considered degrading employments to their inferiors. The Moors had introduced into Spain the cultivation of sugar, cotton, rice, and silk. They had established a system of irrigation which had given fertility to the soil. The province of Valencia in their hands had become a model of agriculture to the rest of Europe. In manufactures and commerce they had shown equal superiority to the Christian inhabitants, and many of the products of Spain were eagerly sought for by other countries. All these advantages were sacrificed to an insane desire for religious unity.

The resources of Spain, already exhausted, never recovered from this terrible blow. Under these circumstances it was an absolute necessity that the ambitious schemes of previous rulers should be abandoned, and it was fortunate that Lerma was personally inclined to a policy of peace and that events occurred to favour its adoption. The accession of James I in England gave a convenient opportunity for concluding the long war that had been carried on with Elizabeth. English mediation brought about a twelve years' truce in 1607 with the United Provinces, which amounted to a practical recognition of their independence. The death of Henry IV and the regency of Mary de Medici enabled Lerma to arrange an alliance with France, which was cemented by a double marriage. Louis XIII married the infantina Anne of Austria, and Elizabeth of France was betrothed to the son and heir of Philip III. For the moment Spain occupied a higher position in Europe than it had held since the defeat of the Armada. James I was weakened by quarrels with his parliament and by the want of a definite policy. France under the regency had abandoned the attitude of Henry IV and was distracted by internal squabbles. The empire was in the feeble hands of Matthias, and the Austrian Hapsburgs were still divided by the family jealousies that had arisen from the deposition of Rudolph II. The Turks had declined since the days of Soliman the Magnificent with a rapidity characteristic of Oriental power. In the midst of these states Spain, subject to an apparently absolute monarchy, enjoyed much the same prestige as in the best days of Philip II. With the consciousness of power the old ambitions revived. An arrangement was being discussed for the recognition of the archduke Ferdinand as the successor of Matthias in the Austrian territories. Philip III, however, advanced a claim to Hungary and Bohemia on the ground that his mother was a daughter of Maximilian II, whereas Ferdinand was only descended from that emperor's brother. The claim was by no means indisputable, but it was inconvenient to Ferdinand to have to discuss it. He agreed therefore to purchase the support of Spain by ceding Alsace, and the vacant imperial fief of Friaule in Italy (1617), and on these terms he succeeded in effecting his designs. Thus a prospect was opened to Spain of connecting its Italian possessions with the Netherlands and of forming a compact Spanish dominion in central Europe. At the same time the old policy of advancing Roman Catholicism was resumed, as the success of Ferdinand promised to secure a signal victory for the Counter-Reformation in Germany. But this forward policy was distasteful to Lerma, who found it necessary to retire in 1618. His withdrawal from affairs was not accompanied by any loss of the royal favour, and the offices which he had held were conferred upon his son, the duke of Uzeda.

The alliance between the two branches of the house of Hapsburg was not finally completed by the arrangement with Ferdinand. It was vigorously urged by Onate, the Spanish representative at Vienna, by Khevenhüller, the

Thirty
Years
War

Austrian envoy at Madrid, and by the Spanish party, headed by Zuñiga, which had always opposed the policy of Lerma. But neither Uzeda nor the royal confessor Ahaga was in favour of an alliance by which Spanish blood and treasure were to be expended in securing the interests of Austria. Philip III, however, was gained over by an appeal to his religious feelings, and in January 1620 he undertook to send assistance in men and money to Ferdinand II. Thus Spain was involved in the Thirty Years' War, which had been commenced in 1618 by the revolt of Bohemia against Ferdinand, and the acceptance of the crown by the elector-palatine Frederick V. Spanish troops from Italy aided Tilly to win the battle of the White Hill, and Spinola led an army from the Netherlands against the Palatinate. But the party of peace was still strong in Spain. Frederick V was the son-in-law of James I., and his complete humiliation would hinder the long cherished project of a marriage between Prince Charles and the Spanish infant. The truce with Holland would expire in April 1621, and if the war was to be resumed with the Dutch it was essential to isolate them by concluding the alliance with England. Moreover, the finances of Spain were by no means in a condition to support the extraordinary expenses of a European war. All these considerations pointed to peace, and Philip III was on the point of recalling Lerma, when he died in March 1621. His reign had not been glorious or advantageous to Spain, but it contrasts favourably with those of his successors. Spanish literature and art, which had received a great impulse from the intercourse with foreign countries under previous rulers, reached their zenith during his lifetime. Three writers have obtained European fame—Cervantes, who produced the immortal *Don Quixote* between 1605 and 1613, and two of the most fertile of romantic dramatists, Lope de Vega and Calderon. In the domain of art Spain produced two of the greatest masters of the 17th century, Velazquez and Murillo.

Philip IV

The time which Philip III had spent on his devotions was given by his successor to the more secular pleasures of hunting and the theatre. But Philip IV shared to the full his father's disinclination to burden himself with the cares of government. The office of first minister was given to Zuñiga, the chief advocate of an aggressive policy in the late reign. Lerma and Uzeda were banished from the court. But the chief influence over the administration was exercised from the first by the royal favourite, the count of Olivares, who succeeded to Zuñiga's office on the latter's death. Olivares was a man of considerable industry and ability, though his reputation has suffered from the inevitable comparison with his great contemporary and rival, Richelieu. He conceived the plan of restoring Spain to its former greatness by returning to the policy of Philip II, regardless of the change in the internal resources of the country. All ideas of peace were abandoned, and Spain plunged headlong into the European struggle. The truce with the United Provinces was unpopular because the commercial progress of the Dutch was fatal to the trade of the Spanish Netherlands, and Amsterdam had already begun to take the place of Antwerp. The expiration of the truce in April 1621 was followed by an immediate renewal of the war. To make the war successful it was imperative to secure the alliance with England, but this was sacrificed because the emperor insisted upon confiscating the Palatinate, which was conferred upon Maximilian of Bavaria. The match with the Spanish infant was broken off, and Prince Charles married Henrietta Maria of France. The alienation of England was enough in itself to ensure the ultimate failure of the Dutch War. On the mainland the succes-

sive stadtholders, Maurice and Frederick Henry, held their own even against the experienced Spinola, and after the latter's recall in 1629 had a distinct advantage. But it was by sea that the Dutch gained their most conspicuous successes. In 1628 the Spanish treasure-fleet was captured by Admiral Hein, whose booty was estimated at seven millions of guilders. The greater part of Brazil, together with Malacca, Ceylon, Java, and other islands, were conquered by the Dutch sailors. Instead of conquering the northern provinces, Spain had to make great exertions to defend the frontiers of the southern Netherlands.

In central Europe the fortune of war was more favourable to Spain and her allies. The crushing defeat of the elector palatine was followed by the humiliation of the Protestant champion, Christian IV of Denmark. Ferdinand II enjoyed for a moment greater power than any other successor of Charles V., and the Edict of Restitution seemed to complete the triumph of the Catholic reaction in Germany. But the revival of the Hapsburg power awakened the jealousy of France, which in 1624 had fallen under the strong rule of Richelieu. The Spaniards had occupied the Valtelline, an important pass which connected Lombardy with Tyrol. A French army expelled the conquerors in 1624, and the treaty of Monçon restored the pass to the community of the Grisons. For a time France was occupied with the suppression of a Huguenot rising, but no sooner had La Rochelle fallen than Richelieu again interfered to thwart the designs of Spain in the question of the Mantuan succession. The Spaniards endeavoured to exclude the duke of Nevers, the rightful heir to the duchy, on account of his connexion with France. But Richelieu forced the Spanish troops to raise the siege of Casale, and ultimately extorted the treaty of Cherasco (1631), by which the emperor recognized the succession of the duke of Nevers in Mantua. The occupation of Pinerolo in this war gave the French an opening into Italy and threatened the ascendancy which Spain had so long exercised in the Peninsula. Meanwhile the victories of Gustavus Adolphus had destroyed the imperial and Catholic ascendancy in Germany. The Spaniards were ignominiously driven from the positions which they occupied on the Rhine.

The death of Gustavus Adolphus at Lutzen inspired the Roman Catholic powers with new hopes. Spain determined to strain every nerve to turn the tide of victory. Philip IV's brother Ferdinand, the cardinal-archbishop of Toledo, was sent to raise troops in Italy and to lead them through Germany into the Netherlands. In 1634 Ferdinand effected a junction with the imperial forces, and their combined efforts won a signal victory at Nördlingen. The Lutheran princes, headed by John George of Saxony, hastened to make terms with the emperor in the treaty of Prague (1635). The Swedes were left almost isolated in Germany, and a speedy termination of the war seemed inevitable. At this crisis Richelieu decided to embark in the war as a principal, and concluded a close alliance with the Dutch against Spain. For two or three years the new policy of France seemed likely to be attended with failure. The French troops, unaccustomed to war, were no match for the trained veterans of Spain. Not only were they repulsed from the Netherlands, but the cardinal infant actually invaded France (1636) and inspired a panic in the capital itself. His success, however, was only temporary, and before long the superior policy of Richelieu gave France the upper hand. The occupation of Alsace, which fell into French hands after the death of Bernhard of Saxe-Weimar, interrupted the connexion between the Netherlands and Italy. In the latter peninsula the French

gained ground and restored the regent of Savoy, whom the Spaniards had expelled. Finally, more important than all, the alliance with Holland gave France the superiority by sea. The destruction of a great Spanish fleet in the Downs, where it had taken refuge under the neutral flag of England, made it almost impossible to send reinforcements from Spain to Brussels. By striking at the points of connexion, Richelieu was breaking the unwieldy Spanish empire to pieces. At this moment his task was immensely facilitated by the outbreak of internal dissensions.

Olivares had been inspired by the success of his great rival with the idea of strengthening Spain by a vigorous policy of centralization. The monarchy consisted of a number of scattered provinces, each ruled by a separate council at Madrid, and each possessed of its own separate institutions. They were held together only by the predominance of Castile and by religious unity. This system Olivares determined to abolish by elevating the royal power to equal absolutism in all the provinces. The dangers from foreign enemies were to be met by forming Spain into one indissoluble whole. But the spirit of provincial independence was still strong, and it was artfully encouraged by the intrigues of Richelieu, who wished to absorb the attention of Spain in its domestic affairs. An edict ordering all able-bodied men to arm for the war, under penalty of confiscation, provoked a revolt in 1640 among the Catalans, who were jealously attached to their old privileges, and whose proximity to the French frontier had already exposed them to intolerable hardships. The Castilian troops were driven from the province, and Catalonia formed itself into a republic under the protection of France. This event exerted a magical influence upon Portugal, where Richelieu's emissaries had also been active, and where the antipathy to Castile was national rather than provincial. In December 1640 a revolution was successfully accomplished in Lisbon, and the crown was assumed by a native noble, John of Braganza, in whose veins ran the blood of the ancient kings. These disasters were fatal to Olivares, to whose system of government they were not unnaturally attributed. In 1643 he was compelled to resign his post, and Philip IV announced his intention of ruling alone.

The revolt of Catalonia and Portugal, together with the undisguised discontent shown by several of the other provinces, could not but hamper Spain in the conduct of the European War. The conquest of Roussillon in 1642 enabled the French to give effectual assistance to the Catalans, who acknowledged Louis XIII as count of Barcelona. The successive deaths of Richelieu (1642) and Louis XIII (1643) made no difference to the policy of France, which was directed by Mazarin under the regency of Anne of Austria. The French had now completely made up the military inferiority which had foiled their efforts at the beginning of the war. In 1643 Enghien (afterwards the great Condé) won the first of a brilliant series of victories at Rocroi, and his success was the more important because it placed the domestic authority of the regent upon a firm footing. The disasters of Spain were increased by the formidable rising of Masaniello in Naples (1647), which was carried on by the duke of Guise and was suppressed with difficulty in 1648. This was followed by the loss of the Austrian alliance through the treaty of Westphalia. As it would have been impossible for Spain to contend single-handed against the hostile coalition, the opportunity was seized to make terms with Holland. This was only achieved by consenting to great sacrifices. Not only did Spain surrender all claims to sovereignty over the northern provinces, but it also ceded to them the northern districts of Brabant, Flanders, and Limburg, with the strong fortresses of Maestricht, Her-

togenbosch (Bois le Duc), Bergen-op Zoom, and Breda. The Dutch retained all their conquests in America and the Indies, and secured themselves from the rivalry of Antwerp by a clause which enjoined the permanent closing of the Scheldt. This marks the final recognition of the United Provinces as an independent state, and also the transference to the northern powers of the maritime supremacy hitherto claimed by Spain.

France and Spain were now left face to face with each other. For the next four years the disturbances of the Fronde gave the Spaniards a great opportunity, of which they were not slow to avail themselves. In the Netherlands they recovered Gravelines, Ypres, and Dunkirk, while Don John of Austria, a natural son of Philip IV, took Barcelona and reduced the Catalans to submission. But the triumph of Mazarin in 1653 enabled France once more to devote itself to the war, although at the same time it drove the great Condé into the Spanish service. The military operations now reduced themselves to a duel in the Netherlands between the rival generals Condé and Turenne. The old tactics, which were adhered to with Spanish obstinacy, were now out of date, and the once invincible infantry was almost useless against the quick movements of light-armed troops which had been introduced by Gustavus Adolphus. The struggle was finally decided by the intervention of England. Both powers had earnestly sued for the support of Cromwell. The rapid advance of the French power was a cogent reason for England to assist Spain, but the religious bigotry that still prevailed at Madrid made the alliance impossible. At last Mazarin gained over the Protector by promising to banish the Stuarts from France and to cede Dunkirk. Reinforced by 6000 Ironsides, probably the best soldiers in Europe, Turenne was irresistible. Dunkirk was reduced after an obstinate defence and handed over to the English, to the great scandal of Roman Catholic Europe. One after another the fortresses of Flanders fell into the hands of the French, and, though the death of Cromwell lost them the support of England, it was impossible for Spain to continue the war. In 1659 Mazarin and Don Luis de Haro, the successor of Olivares, met on a small island in the Bidasoa, and there arranged the treaty of the Pyrenees. Spain had again to make great sacrifices. Besides Artois and several fortresses in the Netherlands, Roussillon and Cerdagne were ceded to France, and thus the Pyrenees were fixed by law as the boundary between the two countries. Louis XIV was to marry the infanta Maria Theresa, who was to receive a large dowry, but was to renounce all eventual claims to the Spanish crown. The only concessions made by France were the pardon of Condé, the recognition of Catalonia as a province of Spain, and the promise to give no more assistance to the Portuguese.

Now that Spain was freed from external hostilities, it seemed possible that the reduction of Portugal might be at last accomplished. But the alliance of France was speedily replaced by that of England, and Catherine of Braganza was married to Charles II. Louis XIV, too, tried to obtain from the Spanish Government an acknowledgment of his wife's claims to the succession, and failing in this he continued to send secret assistance to the Portuguese. A French general, Schomberg, defeated Don John of Austria in 1663, and two years later routed the Spanish forces at the battle of Villa Viciosa. This final disaster crushed the declining energies of Philip IV, who died on September 17, 1665. As his Regency son Charles II. was only four years old, he bequeathed of Maria the government to his widow Maria Anna of Austria, Anna, with a special junta to advise her in the conduct of affairs. As the Spanish monarchy had declined, its

authority had been exercised by a series of chief ministers, —Lerma, Olivares, and Haro,—and this was the only way in which the unity of the executive power could now be maintained. The favour of the queen mother raised to this position her confessor, Father Nithard, a native of Styria. He was a man of ability and experience, and set himself to cope with the most glaring evils of the state. He endeavoured to diminish the public expenditure by limiting the salaries of officials, and by putting an end to the abuses which hindered the commerce with the colonies. But he was soon called upon to face unexpected difficulties. Louis XIV advanced a claim, on behalf of his wife, to certain territories in the Netherlands in virtue of the so-called "law of devolution." This was an old custom by which the children of the first marriage succeeded, to the exclusion of all later descendants. As Spain resisted the claim, the French invaded Flanders and overran Franche Comté. The regent was compelled to purchase the restoration of the latter province by ceding part of Flanders to France in the treaty of Aix-la-Chapelle (1668). At the same time the independence of Portugal was finally acknowledged. These disasters increased the jealousy with which the Spanish nobles regarded the rule of a Jesuit and a foreigner. A strong opposition party was formed under the leadership of Don John of Austria, and in 1669 Nithard was compelled to resign. But among the nobles themselves there was little unity, and a difference arose as to the policy to be pursued when Louis XIV attacked Holland in 1672. The queen-mother was naturally on the side of Austria, and her influence was sufficient to secure the adhesion of Spain to the first European coalition against France. This success she followed up by obtaining the post of chief minister for another favourite, Fernando de Valenzuela, who was appointed marquis of Villafiera and raised to the rank of a grandee of Spain. This revived the jealousy of the nobles, who again formed a league for the maintenance of their privileges under Don John of Austria. This time they were completely successful. Not only was Valenzuela banished, but Maria Anna herself was compelled to retire from the court and to take up her residence in Toledo. Don John was now all powerful. A natural antipathy to the policy of the regent led him to draw aloof from the Austrian alliance and to attach himself to France. A marriage was concluded between Charles II and Maria Louisa of Orleans. It was hoped that by this means better terms would be obtained from Louis XIV, but in the treaty of Nimègue Spain had to surrender Franche-Comté and fourteen fortresses in Flanders. This treaty marks the complete loss by Spain of its position as a first-rate power. Henceforth it could only exist by the support of those states which resented the aggrandizement of France. Don John was no more successful in his domestic than in his foreign policy. His industry was as unwearying as that of Philip II himself, and he determined to rule independently of all interested advisers. The reform from which he hoped most was a revocation of the crown domains which had passed into private hands. But the scheme met with natural opposition from the nobles, and he died in 1679 without having accomplished anything. For a year Charles II endeavoured to rule in person with the help of the ordinary council, but the attempt only showed how the strength of the monarchy was bound up with the personal character of the ruler. "Charles V," says Mignet, "had been both general and king, Philip II was merely king, Philip III and Philip IV had not been kings, Charles II was not even a man." From infancy Charles's health had been so defective that his death had appeared an imminent contingency, and his intellect was as feeble as his body. It was impossible for

Charles II

him to exercise any effective control over the government, and he was little more than a tool in the hands of the nobles, who, under Don Luis de Haro, had recovered much of the political influence from which Olivares had excluded them. In 1680 the office of first minister was given to the greatest of Spanish magnates, the duke of Medina-Celi. It was at this time that Louis XIV was conducting his famous *réunions*, and the weakness of Spain enabled him to annex without opposition Courtrai, Dinmude, and the great fortress of Luxemburg. Medina-Celi, disgusted with his thankless task, resigned in 1685, and his place was taken by Count Oropesa. The new minister revived the alliance with Austria, and Spain became a member of the league of Augsburg in 1686. The success of the league seemed to be almost assured by the Revolution which gave the crown of England to William III, the leader of the opposition to Louis XIV. But in spite of apparently overwhelming odds France more than held her own, and Spain was humiliated by the capture of Urgel and Barcelona. Ministers held office only at the will of court factions, and the first disaster was fatal to Oropesa. Spain continued to play a secondary part in the war, which was concluded in 1697 by the treaty of Ryswick, the first for many years in which France did not obtain any addition of territory. The chief motive for Louis XIV's moderation was the desire to devote his attention to the approaching question of the Spanish succession.

The decline of Spain in the 17th century is not to be measured by its territorial losses. Holland had extorted a tardy recognition of its independence, Portugal was once more a separate kingdom, Catalonia was reduced only to very doubtful submission, France had seized upon Roussillon and Cerdagne, Franche Comté, and great part of the southern Netherlands, French influence had been established in Italy as a counterpoise to that of Spain. But the weakness of the extremities, to which these facts bear conclusive testimony, was the result of still greater weakness at the centre. The population of the peninsula, estimated at twenty millions under the Arabs and at twelve under Ferdinand and Isabella, had fallen to less than six millions in the reign of Charles II. This decrease of numbers was doubtless due in the first place to the religious bigotry which had condemned thousands of Jews and Moriscos to death or exile, but it is partly traceable to a fatal decline in the economic prosperity of the country. Agriculture, for which many parts of Spain were peculiarly fitted, had suffered from the departure of the Moriscos and from a number of other causes. The want of any law of mortmain had led to the accumulation of at least one fourth of the land in the hands of the monasteries, the most charitable but the most careless and conservative of landlords. Thanks to their obstinate adherence to obsolete methods of cultivation, their estates produced little more than one per cent. on the outlay. The system of entail, which earlier monarchs had striven to restrict, made enormous strides in the 16th century, and most of the secular estates were unreasonably concentrated in the hands of a few great nobles, who lived at Madrid and spent their revenues in lavish extravagance without any regard to the interests of their tenants. In the fertile provinces of Andalusia and Estremadura agriculture was entirely ruined by the system of sheep-farming. In the 12th century, when the country was exposed to the destructive forays of the Moors, the inhabitants had been forbidden to enclose their lands with either hedges or ditches, and successive kings had encouraged the rearing of huge flocks of sheep which could easily be driven over the open country into a place of safety. In the 16th and 17th centuries the condition

Decline
Spain
the 17th
century

of things had entirely changed, but the old regulations were jealously maintained by the company of *La Mesta*, one of the most powerful and independent corporations in Spain. This body, which derived large revenues from the sale of wool, was enabled to retain its privileges intact until the reign of Charles III. Every summer their flocks poured down the northern mountains, and the absence of enclosures made it impossible to defend the crops from their ravages. Besides making agriculture impossible, the exclusive attention to sheep-rearing led to the gradual disappearance of the old forests, and, as no one ventured to plant new trees, great parts of Castile became an arid desert. Every kind of industry suffered in the same way as agriculture. The true Spaniard despised all who earned a living by handicraft, and when the Moriscos had been banished it was impossible to obtain skilled artisans except by importing them. The Spaniards could not even cut their own timber into ships or construct fortifications for their own towns. Madrid and other cities were crowded with foreigners, who hastened to make a fortune that they might carry it back to their native land. The Government was quite as much to blame as individuals. The gold from the New World would have enabled Spain to command the markets of Europe, but the mediæval restrictions on the exportation of the precious metals were strictly enforced. The high price of commodities was attributed, not to the superfluity of the medium of exchange, but to the competition of foreign and colonial markets. It was forbidden to export one article after another, and the colonies were expected to send gold without receiving anything in exchange. A more ruinous policy could hardly be conceived, but it was supported by the merchants themselves, who refused to fill their vessels with anything but gold and silver, and left the indigo, cotton, and other commodities to the English and the Dutch. Domestic production, crippled by these restrictions, was almost destroyed by the excessive taxation rendered necessary by the ambitious schemes of Philip II. and his descendants. It is notorious that Austria could never have carried on the Thirty Years' War so long but for the supplies received from Spain. Spain in fact, was the great subsidizing power in the 17th century, as England was in the 18th. The enormous expenditure thus necessitated was wrung from the classes least able to pay it, as the Government was not strong enough to attack the exemption of the nobles and clergy. The *alcavala*, the tax on sales which Ximenes had abolished, was restored under Philip II., and in the 17th century reached the enormous amount of 14 per cent. The traders naturally sought to evade a tax which it was impossible to pay. But this only increased the vigilance of the revenue officers, who endeavoured to collect the tax at every opportunity, on the raw material, on the manufactured product, and again every time that it changed hands. Taxation in Spain was a caricature of Alva's system in the Netherlands, and was even more ruinous than that had been. Foreign nations reaped all the advantages which the short-sighted policy of the Spaniards threw away. It has been calculated that five sixths of the manufactured commodities consumed in Spain were provided by foreigners, and that they carried on nine tenths of the commerce with the Spanish colonies. By law all foreign trade with the colonies was prohibited, but the decline of native industry made it impossible to enforce the laws, and the Spanish Government had to connive at a contraband trade of which other countries gained all the profit. The policy of the earlier kings had made the colonies dependent upon European products, and when Spain could no longer supply them they had to be obtained elsewhere. Circumstances in the latter half of

the 17th century allied Spain with England and Holland against France, and the English and Dutch founded their commercial supremacy upon the trade which Spain threw into their hands. The country which had sent a hundred vessels to Lepanto, and which in 1588 had despatched the great Armada against England, was reduced under Charles II. to borrowing Genoese vessels to maintain its connexion with the New World. The army, which had once been the terror of Europe, had sunk at this time to an effective force of little more than 20,000 men. In literature and art the decadence of Spain was equally conspicuous and complete. The religious unity of the country was preserved, but all touch with the intellectual advance of Europe was deliberately sacrificed.

In spite of its loss of power and prestige, the crown of Spain was still regarded as a prize well worth winning. Ever since Charles II's accession the Spanish succession had been a prominent question for European diplomacy, and from 1697 it became the pivot on which international relations turned. Charles II's first wife, Maria Louisa of Orleans, had died childless in 1689, and his second marriage to Maria Anna of Neuburg was equally unfruitful. The male line of the Spanish Hapsburgs was evidently on the verge of extinction, and by law and tradition the crown would pass to the nearest female or her heir. But the question was complicated in many ways. Of Charles II's two sisters, the elder, Maria Theresa, had married Louis XIV., and had renounced her claims, but her husband had always protested against the renunciation, and the non-payment of the stipulated dowry gave him an argument for its nullity. The younger, Margaret Theresa, had married the emperor Leopold I., and had made no renunciation, but she had since died, leaving an only daughter, Maria, who married the elector of Bavaria. Going a generation back, the two sisters of Philip IV. had also married into the houses of Bourbon and Hapsburg. Anne of Austria, whose renunciation of the Spanish crown was undisputed, was the mother of Louis XIV., while Maria Anna was the mother of Leopold I. Ever since the division of the house of Hapsburg into two branches it had been agreed by a family compact that if either became extinct the other should succeed to its territories. Leopold I. was extremely anxious to restore the unity of the family by securing the observance of this compact, and he had a great advantage in the fact that Charles II.'s mother was his own sister, and Charles's second wife was his sister in law. The will of Philip IV. had arranged that, after Charles II. and his descendants, the crown should pass, first to Margaret Theresa and her children, and secondly to Leopold and his children. It was a great disappointment to Leopold that his first wife left him only a daughter, but he tried to secure the claims of his family by extorting from her on her marriage a renunciation of her rights to the crown of Spain. This renunciation the Spanish Government had never recognized, and the queen-mother, whose adherence to the Hapsburg interests was overcome by her feelings for her own family, induced Charles II. to make a will in 1696 in which he named Joseph Ferdinand, the infant electoral prince of Bavaria, as his heir. But the queen-mother's death withdrew the dominant influence at the court of Madrid and enabled the Austrian envoy, Count Harrach, with the help of the queen, to procure the revocation of this will. The succession now became the subject of party quarrels and intrigues, in which the rival envoys of Austria and France took a prominent part. The aim of Leopold I. was to obtain the succession of his second son, the archduke Charles, while Louis XIV. hoped to procure the Spanish crown, if not for his son, at least for one of his grandsons. The office of first minister

in Spain had not been filled up since the fall of Oropesa, and the most influential man in the kingdom was Cardinal Portocarrero, archbishop of Toledo. He was a bitter opponent of the queen, who was extremely unpopular, and all his efforts were directed to thwart the schemes of Austria. To depress the cardinal, Maria Anna induced Charles II. to recall Oropesa, but the latter declined to return to the Austrian alliance which he had previously championed, and espoused the cause of the electoral prince. There was no semblance at this time of a French party in Madrid, but Louis XIV. availed himself of the cessation of hostilities to send thither an able diplomatist, Count Harcourt, who speedily contrived to exercise considerable influence over the course of events.

Too many European interests were involved in the succession to allow it to be settled as a mere question of domestic politics. The idea of the balance of power dominated European diplomacy at this time, and William III. of England was its avowed and recognized champion. England and Holland, the two countries with which William was connected, were vitally interested in the Spanish trade. The accession of a French prince in Spain would almost inevitably transfer to France all the advantages which they at present enjoyed. It was obvious that William III. must have a voice in the settlement of this succession, and Louis XIV., who had no desire for a new European war, was willing to recognize this. The negotiations between England and France resulted in the first treaty of partition (October 11, 1698). The electoral prince was to receive the bulk of the Spanish empire, viz., Spain itself, the Netherlands, Sardinia, and the colonies, the dauphin was to have Naples, Sicily, Finale, and Guipuzcoa, while Lombardy was to go to the archduke Charles. This treaty had one fatal defect—that it was based solely on the interests of the contracting powers and took no account of the wishes of the Spaniards, who resented any proposal for the division of the empire. The first hint of the treaty irritated Charles II. into making a second will in November in favour of the electoral prince, and all parties in Spain agreed in its approval. But within three months both treaty and will were rendered null by the sudden death of the infant prince (February 1699), and the question, thus reopened, became more thorny than ever, as the choice now lay definitely between Austria and France. It seemed almost impossible to prevent the outbreak of a general war, but William III. patiently reunited the broken threads of his diplomacy, and arranged with France a second treaty of partition. The Spanish monarchy was to be divided into two parts. The larger, consisting of Spain, the Netherlands, Sardinia, and the colonies, was to go to the archduke Charles. The dauphin was to receive the share stipulated in the former treaty, with the material addition of Lorraine. The duke of Lorraine was to be compensated with the Milanese. This treaty, unlike the first, was communicated to Austria, but the emperor, who was now confident of securing the whole inheritance, refused to accept it.

Meanwhile the death of the electoral prince had destroyed the temporary unanimity at Madrid. Portocarrero and his partisans were gained over to the side of France by Harcourt. Oropesa fell back upon a scheme of his own for uniting the whole Peninsula under the king of Portugal. The queen returned to her old allegiance to her brother-in-law, and formed a close alliance with Harrach for the advancement of the interests of the archduke Charles. A popular rising overthrew Oropesa and enabled Portocarrero to regain his ascendancy. At this juncture came the news of the second partition treaty, which again irritated the tender susceptibility of the

Spaniards. The Austrian party hoped to utilize the popular feeling against Louis XIV. as a party to the hated treaty. But Harcourt adroitly contrived to suggest that the best way of annulling the partition project was to enlist Louis's own interests against it. The view steadily gained ground that the house of Bourbon was the only power strong enough to secure the unity of the Spanish empire. Portocarrero succeeded in inducing Pope Innocent XII. to support the French claim. Charles II., feeble to the last, succumbed to this combination of influences, and signed a testament bequeathing the succession to Philip of Anjou, the second grandson of Louis XIV., on condition that he would renounce all claims to the crown of France (October 3, 1700). Thus his last act was to disinherit his own family in favour of the enemy with whom he had been at war almost all his reign. He died on the 1st of November 1700.

Everything now depended upon the decision of Louis XIV. The treaty of partition offered substantial advantages to France, Charles II.'s will would exalt the house of Bourbon above every other family in Europe. His hesitation, whether real or feigned, did not last long. On November 16 he introduced his grandson to the French court as Philip V. of Spain. The dynastic ambition of Philip V. the king was also based upon sound policy. In the face of Spanish opinion and of the emperor's refusal it was impossible to carry out the partition treaty. And for the moment it appeared that the accession of a Bourbon prince would be secured without difficulty. Philip V. was proclaimed in all parts of the Spanish monarchy amid popular acclamations. Leopold I. protested and prepared to attack Lombardy, but he could not hope to obtain the whole succession for his son without the assistance of the maritime powers. William III., who saw the aims of his life threatened with ruin, was eager for war, but his subjects, both in England and Holland, were resolute to maintain peace. In these circumstances Louis XIV. played into the hands of his enemies. He expelled the Dutch garrisons from the fortresses of the Netherlands which they had occupied since the treaty of Ryswick, and replaced them by French troops. He showed a cynical intention to regard Spain as a province of France, and he took measures to secure for the French the commercial advantages hitherto enjoyed by England and Holland. William III. was thus enabled to conclude the Grand Alliance (September 7, 1701), by which the contracting powers undertook to obtain the Netherlands and the Italian provinces of Spain for the archduke Charles and to preserve the mercantile monopoly of the English and Dutch. A few days afterwards James II. died at St. Germain, and Louis XIV. was injudicious enough to acknowledge his son as king of England. This insult exasperated public opinion in that country, the Tory parliament was dissolved, and the last obstacle to William's warlike policy was swept away. William himself died in March 1702, but he left the continuance of his policy to the able hands of Marlborough and Hensius. The war which the emperor had commenced single-handed in 1701 became general in the next year.

It is needless to follow the military operations of the War of the Spanish Succession, which have been rendered famous by the exploits of Eugene and Marlborough. The chief scenes of hostilities were the Netherlands, Germany, and Italy, in each of which the French suffered fatal and humiliating reverses. At first the peninsula of Spain was not directly concerned in the war. The Grand Alliance did not aim at excluding Philip from the Spanish monarchy as a whole, but only from those parts which the maritime powers wished to preserve from French influence. But in 1703 Pedro II. of Portugal deserted the cause of

the
Spanish
succession.

France and concluded the Methuen treaty with England. This opened the Peninsula to the allied forces and necessitated a revision of the terms of the alliance. Pedro's support could only be purchased by the expulsion of the French from Spain, and the allies now determined to claim the whole Spanish inheritance for the archduke Charles. In 1704 the archduke appeared in Portugal, and the English fleet, under Sir George Rooke, captured Gibraltar. As the assistance of the Portuguese was only half-hearted, it was decided in 1705 to seek a new opening in the east. Catalonia, always inclined to revolt against its rulers, and recently irritated by the conduct of Philip V, offered a convenient base of operations. The brilliant but eccentric earl of Peterborough succeeded in capturing Barcelona, and by the end of the year the archduke was acknowledged as Charles III in Catalonia, Valencia, and Aragon. A great effort on the part of Philip to recover the lost provinces was repulsed, and a simultaneous advance of the allies from the east and from Portugal compelled him to evacuate Madrid, where Charles III. was formally proclaimed. But the provincial disunion, which had so often hampered the Hapsburg kings, proved the salvation of their Bourbon successor. The Castilians refused to obey a king who was forced upon them from Aragon, and their religious instincts were offended by the alliance of Charles with the heretics of England and Holland. Disunion among the allies aided the revolt of Castile, and by the end of 1706 Charles III. found himself compelled to evacuate his recent conquests and to return to Barcelona. In 1707 the allies attempted another invasion of Castile, but they were routed by the duke of Berwick at Almanza, and Aragon and Valencia were forced to return to their allegiance to Philip V. For the next two years the war in the Peninsula languished. Charles III. received reinforcements from Austria under Stahremberg, but he was unable to do more than retain his hold upon Barcelona. In 1710 the cause of the allies received a new impulse from the arrival of Stanhope with supplies of men and money from England. Under the joint command of Stanhope and Stahremberg the army advanced westwards from Barcelona, defeated Philip V at Almenara and Saragossa, and for the second time occupied Madrid. The disasters which the French had experienced in other parts of Europe had broken the pride of Louis XIV., and he was prepared to purchase peace by sacrificing his grandson. A treaty would have been concluded to this effect at Gertruydenburg, if the allies had not insisted that the French troops should be employed in forcing Philip V to accept it. Louis XIV. refused to take arms against his own family, and a sudden change in the current of fortune saved him from the humiliation which his enemies wished to force upon him. Charles III. found it impossible to maintain Madrid in face of the enthusiasm of the Castilians for his rival. The capital of Spain was of no importance from a military point of view, and the allies determined on its evacuation. On their retreat they were followed by Vendôme, whom Louis XIV. had sent to his grandson's assistance. Stanhope, attacked at Brihuega, was compelled to capitulate with all his forces before Stahremberg could arrive to his assistance. The latter was defeated after an obstinate struggle at Villa Viciosa. Aragon and Valencia again submitted to Philip, and the archduke was once more confined to Catalonia.

At this juncture two events occurred which completely altered the balance of the contending powers. The fall of the Whig ministry through a court intrigue gave the control of English policy to the Tories, who had always been hostile to the war. The death of Joseph I. in April 1711 left the Austrian territories to his brother, the archduke

Charles, who was soon afterwards elected emperor as Charles VI. To allow him to obtain the Spanish succession would be to revive the empire of Charles V., and would be even more dangerous to the balance of power than the recognition of Philip V. with adequate securities against the union of France and Spain. The object for which the allies had been making such immense exertions was now a result to be averted at any cost.

In these altered circumstances, Bolingbroke, the English minister, hurried on the negotiations with France which resulted in the treaty of Utrecht between England, France, Spain, and Holland. Philip V. was acknowledged as king of Spain, on condition that he should formally renounce all eventual claims to the crown of France. But the partition of the Spanish monarchy was insisted upon by the allies. The Netherlands were to be handed over to Austria, on condition that the Dutch should garrison the barrier fortresses. Austria was also to receive the Italian provinces of Spain, with the exception of Sicily, which was given to the duke of Savoy with the title of king. England naturally obtained considerable advantages from a war in which she had borne so prominent a part. The acquisition of Gibraltar and Minorca gave her the control of the Mediterranean. The *asiento* conferred upon her the privilege of importing slaves into the Spanish colonies, and she also obtained the right of sending a single vessel into the South Seas. France had to recognize the Protestant succession, and to cede Newfoundland, Acadia (Nova Scotia), and Hudson's Bay. Charles VI. refused to accept the terms offered to him at Utrecht, but he found it impossible to carry on the war by himself, and in 1714 he made peace with France by the treaty of Rastatt. But he still retained the title of king of Spain, and showed no willingness to acknowledge Philip V.

The great blot on the conduct of the allies in arranging the treaty of Utrecht was the desertion of the Catalans, who had rendered such loyal services during the war. They were left to the tender mercies of Philip V., who sent Berwick to reduce the rebellious province. Barcelona resisted for many months with the heroism of despair, and was well nigh reduced to ashes before it could be taken (September 1714). With its fall all resistance came to an end. The three Aragonese provinces were deprived of the last remnants of their ancient privileges, and were henceforth ruled from Madrid under Castilian laws.

With the final accession of a Bourbon king Spain entered upon a new period of history, in which it once more played a considerable part in European politics. The death of Louis XIV. (1715), and the acquisition of the regency in France by the duke of Orleans, destroyed the close connexion that had hitherto existed between France and Spain. Philip V. was hypochondriacal and bigoted, the slave of his wife and his confessor, but he had certain definite schemes to which he clung with the obstinacy of a weak character. In spite of his solemn renunciations and the guarantee of the European powers, he never relinquished the idea of ultimately succeeding to the French throne. In what was regarded as the probable event of Louis XV.'s death, he was determined to enforce his hereditary claim, even if he had to resign the crown of Spain. His interests were diametrically opposed to those of the duke of Orleans, who was, after Philip's family, the natural heir to Louis XV. Philip V. had one other guiding passion, enmity to Charles VI., who had robbed the Spanish monarchy of its fairest provinces in Italy. These provinces he set his heart upon regaining, and in this project he was encouraged by the two people who had most influence over him,—his wife and his minister.

Philip V.'s first wife, Maria Louisa of Savoy, had died in 1714, leaving him two sons, Louis and Ferdinand. A suc-

Adminis-
tration of
Alberoni.

cessor was speedily found for her in the person of Elizabeth Farnese, niece of the duke of Parma, who was suggested by Alberoni, at that time agent for Parma at Madrid. The new queen speedily obtained unlimited ascendancy over her husband's mind, and she displayed an unbridled ambition and a capacity for intrigue astounding in one who had been brought up in complete retirement. As Philip's sons by his first wife would exclude her own children from the Spanish throne, she was anxious to obtain for the latter the reversion of the duchies of Parma and Tuscany, to which she had an eventual claim. With this end in view she encouraged her husband's designs in Italy, while personal ambition made her eager to see him on the French throne. Her favour gave the conduct of Spanish affairs for a short period to her countryman Alberoni, one of the strangest personages of the 18th century. The son of a gardener at Piacenza, he had sought a career in the church, and had come to Spain in the suite of Vendôme, whose favour he had won by combining the functions of a cook and a buffoon. After the death of his patron he remained in Spain, and conceived an ardent affection for the country of his adoption. Raised to power by the part he had played in effecting the king's marriage, he determined to exalt Spain from its long depression to the position it had once occupied in Europe. His domestic reforms showed that he had a real capacity for government. Commerce and industry revived under his patronage, the army was reorganized, and the revenue increased. But his chief attention was given to the navy, the real foundation of the former greatness of Spain. Foreigners who had known the country under Charles II or during the Succession War were astounded at the strides which it had made under the new administration. Alberoni himself is said to have assured Philip that with five years of peace he would make him the most powerful sovereign of Europe. But these years of peace he was not destined to have. Alberoni cordially approved the Italian designs of Philip, and hoped to employ the restored might of Spain in freeing his native country from the hated rule of Austria. He had less sympathy with the king's hankering after the French crown and his enmity to the regent Orleans. But he held office only by the royal favour, and could not venture to set up his own will against that of his master. He was convinced, and not without reason, that everything would go well if he could secure the English alliance.

But the attitude of Spain had already awakened suspicion in France, and the ready mind of Dubois had conceived a plan for thwarting Alberoni. He determined to desert the policy of Louis XIV and to conclude a close alliance between France and England. This was to be based upon the common danger from rival pretenders, which urged the houses of Orleans and Hanover to maintain the provisions of the treaty of Utrecht. An agreement was arranged between the two states in 1716, and, being joined by Holland in January 1717, was known as the Triple Alliance. This was a great blow to Alberoni, and made him anxious to postpone all hostilities until his preparations were complete. But his hand was forced by the indignation excited in Philip V's mind by an insult offered to him by the emperor. The grand inquisitor of Spain was arrested in Lombardy as a rebel against Charles III, his lawful king. Philip V decided for an immediate rupture, and Alberoni against his will had to send an expedition to Sardinia, which overran the island in 1717. The enthusiasm excited in Spain by the unwonted news of a military success was increased in 1718 when another Spanish force occupied Sicily. But meanwhile Charles VI had appealed to France and England for assistance against this rupture of the treaty of

Utrecht. The Triple Alliance, reinforced by the junction of Austria, became the Quadruple Alliance (August 1718). The resolution of the allies was convincingly displayed in a naval encounter in which Admiral Byng destroyed the Spanish fleet off Cape Passaro.

Hitherto the only fault to be found with Alberoni's schemes is that they were attempted prematurely, and this was the fault of the king rather than of the minister. But the Quadruple Alliance drove him in despair to form those far-reaching projects which are generally associated with his name, and which have given rise to the unjust impression that his whole policy was chimerical and unsound. To meet the hostility of England and France he must make use of internal divisions. He invited the Pretender to Spain, prepared an expedition in his behalf, and concerted with Count Gorz, the minister of Charles XII, a grand scheme by which Sweden and Russia were to combine in supporting the Jacobites against George I. At the same time, through the Spanish envoy Collamare, he organized a conspiracy among the numerous opponents of the regent. All these schemes broke down simultaneously. Charles XII was killed at the siege of an obscure town in Norway, Gorz was executed by his successor, the Spanish fleet which was to carry the Pretender to England was wrecked, the conspiracy of Collamare was discovered and suppressed. France declared war, and sent an army under Berwick across the Pyrenees. An English fleet gratified the national love of a maritime monopoly by burning along the Spanish coast the vessels and docks which Alberoni had created. The emperor, who had just ended a war with Turkey by the treaty of Passarowitz, was able to send a force which succeeded in recovering Sicily. Alberoni was sacrificed to appease the enemies of Spain, and was exiled from the kingdom he had served so loyally in December 1719. A month later Philip V accepted the terms imposed upon him by the Quadruple Alliance. He had to confirm his renunciation of the French crown, and also to abandon all claims on the provinces of Spain which had been ceded to Austria by the treaties of Utrecht and Rastatt. He also allowed the emperor to retain Sicily, the duke of Savoy being compensated with Sardinia. On the other hand Charles VI's pretensions to the Spanish crown were definitely abandoned, and the allies recognized the eventual claims to Parma and Tuscany of Philip's children by his second marriage, on condition that those duchies should never be united with Spain.

In spite of the conclusion of peace, Philip continued to cherish his animosity against Charles VI, especially as the latter showed an inclination to evade the condition about Parma and Tuscany by encouraging other claimants to come forward. To gratify this passion, Philip went so far as to lay aside his old enmity against the duke of Orleans, and to authorize the negotiation of a close alliance with France. His oldest son, Don Luis, was married to a daughter of the regent, and Louis XV was betrothed to the infanta Maria Anna. But the death of Orleans in 1723 gave a new direction to the king's policy. In 1724 Europe was astounded by the news that Philip had abdicated in favour of Don Luis, and had gone into retirement at San Ildefonso. This act was generally attributed to the indolence and superstition which formed the basis of his character, but the real motive was undoubtedly a desire to remove the chief obstacle to his accession in France. Louis XV, however, disappointed his expectations by continuing to live, and the queen soon wearied of her unwonted seclusion. Luis only survived his accession eight months, and to the surprise of the world Philip V emerged from his retreat to resume the crown which he had laid down of his own accord.

Ripperda.

The queen returned to power more determined than ever to carry out her favourite scheme of obtaining an Italian principality for her eldest son Don Carlos. As France and England had shown themselves lukewarm in the matter, she resolved to turn to her husband's enemy, Charles VI. This scheme was suggested by a Dutch adventurer, Ripperda, who inspired Elizabeth with a belief that the Austrian alliance would enable her not only to effect her object in Italy, but also to regain Gibraltar and Minorca for Spain. This was rendered the more probable by the fact that Charles VI. had quarrelled with England about the foundation of the Ostend Company. The conduct of the affair was entrusted to Ripperda himself, and while he was at Vienna a great impulse was given to the negotiation by a complete rupture between Spain and France. The duke of Bourbon, who had become chief minister in France after the death of Orleans, had set himself to reverse the policy of his predecessor. To complete this, he sent the infanta back to Spain and married Louis XV. to Maria Leczinska, daughter of the ex-king of Poland. This insult removed the last scruples of Philip V. about the Austrian alliance, and in April 1725 Ripperda concluded the treaty of Vienna. The mutual renunciations arranged by the Quadruple Alliance were confirmed. Spain recognized the settlement of the Austrian succession by the Pragmatic Sanction and promised great commercial privileges to the Ostend Company, while Charles VI. pledged himself to secure the succession of Don Carlos in Parma and Tuscany, and to use his influence with England to obtain the restitution of Gibraltar and Minorca. By a secret treaty Charles further undertook, in the case of England's refusal, to assist Spain with arms and also to send aid to the Jacobites. These terms were soon divulged by the indiscreet vanity of Ripperda himself, and England and France formed the counter-league of Hanover (September 1725), which was also joined by Frederick William I. of Prussia, though only for a short time.

Ripperda returned to Spain, to be rewarded with the office of chief minister. But his success seems to have turned his head, his boasts about the grand results to be expected from the Austrian alliance proved to be ill founded, and his fall was as sudden as his rise had been. After a brief period of exile in England, he sought a new home in Morocco, where he became a convert to Islam and died in 1737. But his policy was continued by his successor, Don Joseph Patiño, who sent a fleet to lay siege to Gibraltar. Europe was now divided into two hostile leagues, but the outbreak of a general war was averted, partly by the pacific inclinations of Walpole in England and Henry in France, and partly by the growing coolness between Austria and Spain. Charles VI. had been led into the treaty of Vienna by a momentary pique against England, but he soon realized that he had more to lose than to gain by favouring the Spanish designs upon Italy. Accordingly, in May 1727, while the siege of Gibraltar was proceeding, he threw over his obligations to Spain and signed the preliminaries of a peace with England and France. The Ostend Company was suspended, and the questions about Parma, Tuscany, and Gibraltar were referred to a European congress at Soissons. The Spanish Government found it impossible to hold out in isolation, and accepted these terms by the convention of the Pardo (March 1728).

The congress of Soissons was a complete failure, and the irrepressible energy of the Spanish queen discovered a new method of obtaining her ends. The birth of a son to Louis XV. removed into the background all idea of the succession in France, and the attitude of Charles VI. proved that he would do nothing for Don Carlos. Under

these circumstances there was no alternative but to sacrifice the prospect of recovering Gibraltar and Minorca and to seek the alliance of England and France. By the treaty of Seville (November 1729) these powers, with Holland, concluded an offensive and defensive alliance with Spain. The privileges which the latter country had conferred upon the Ostend Company were revoked. Don Carlos was recognized as the heir to Parma and Tuscany, and to enforce his claims these provinces were to be occupied by 6000 Spanish troops. Charles VI., astounded at this sudden change in the aspect of affairs, took active steps to oppose this occupation of the duchies. He collected 30,000 troops in Italy, and when the old duke of Parma died in January 1731 he seized his territories as an imperial fief. Elizabeth called upon her allies to carry out the treaty of Seville, but Walpole and Fleury were unwilling to resort to hostilities. Luckily Charles VI. thought more of securing his daughter's succession in Austria than of anything else. By promising that England would guarantee the Pragmatic Sanction, Walpole induced the emperor to conclude the second treaty of Vienna (March 1731), which dissolved the Ostend Company and confirmed the provisions of the treaty of Seville. In 1732 English ships conveyed Don Carlos and the Spanish troops to Italy. Parma and Piacenza were immediately occupied, and the grand-duke of Tuscany acknowledged Don Carlos as his heir.

In the long and intricate series of negotiations of which we have given a brief summary the guiding thread is the grasping ambition of the queen of Spain. That ambition was by no means satisfied by the results obtained in the treaty of Vienna. Austria still held the Italian provinces of Spain and was looking out for an opportunity to expel Don Carlos from central Italy. England retained her hold upon Gibraltar and Minorca, and claimed a maritime and colonial supremacy which threatened to thwart all schemes for the revival of Spanish commerce. Elizabeth never relinquished for a moment the hope of humiliating England and expelling the Hapsburgs from Italy. Circumstances at this time were more favourable than they had ever been before. The able administration of Patiño, "the Colbert of Spain," had restored order in the Spanish finances, and had already made considerable strides towards the creation of a formidable fleet. But the great advantage lay in the fact that the death of Orleans and the birth of children to Louis XV. had removed all obstacles in the way of an alliance between Spain and France. The close union between the two branches of the house of Bourbon, which the Grand Alliance had endeavoured to avert, and which circumstances had postponed for twenty years, was now to become an accomplished fact. In 1733 "an eternal and irrevocable family compact" was signed by the Count Rottembourg and Don Joseph Patiño. France and Spain pledged themselves to pursue a common policy in regard both to Austria and England, the object of which was to destroy the Italian ascendancy of the one and the commercial monopoly of the other. This treaty, which constituted a danger to Europe hardly less than the aggressions of Louis XIV., was kept a profound secret, and, though its existence was more than suspected at the time, its full importance has not been apprehended until recent times.

The first opportunity for carrying out this common War of policy was offered by the dispute about the Polish suc- the Polish sion which broke out in 1733 between Stanislaus Leczinski and Augustus III. of Saxony. Austria and Russia supported the latter prince, while Louis XV. espoused the cause of his father-in-law. But the war in Poland itself was of very secondary importance compared with the hostilities to which it gave rise in southern Europe,

France, Spain, and Sardinia concluded the league of Turin (October 1733) for the partition of Charles VI's Italian provinces. The chief events of the war, from the Spanish point of view, were the occupation of Naples and Sicily by Don Carlos. It was intended that he should keep these kingdoms, and that Parma and Tuscany should be transferred to his younger brother Don Philip. But Fleury, seeing an opportunity of securing his own ends, refused to continue the war for the aggrandizement of Spain. In 1735 he concluded the preliminaries of a peace with Austria by which Don Carlos was to be recognized as king of the Two Sicilies, Charles VI was to be compensated with Parma, and his son-in-law was to receive Tuscany in exchange for Lorraine, which was eventually to pass to France. The Spanish queen was bitterly indignant at the desertion of her ally, at the cession of her native Parma to Austria, and at the failure to provide anything for her second son. She struggled hard to prolong the war, but the only result of her manœuvres was to postpone the conclusion of the definitive treaty until 1739, when the preliminaries were confirmed.

War of
Jenkins's
ear

Meanwhile Spain had become involved in a maritime quarrel with England. The restrictions imposed by the treaty of Utrecht upon English trade with the Spanish colonies had been systematically evaded by the development of a system of organized smuggling on the part of the British traders. The Spaniards, encouraged by the secret compact with France, refused to tolerate an abuse which their weakness had compelled them to connive at in the previous century. To put a stop to it they rigidly enforced their right of search, often seizing British vessels on the high seas and treating the crews with gross brutality. This gave rise to great ill feeling between the two nations, which was increased by other colonial disputes about the right of gathering logwood in Campeachy Bay and on the frontiers of Florida. The popular indignation in England, which Walpole's opponents fanned for their own purposes, was raised to fever heat by the story of Jenkins, an English captain, who maintained that he had been tortured and his ears cut off by a Spanish *guarda costa*. Walpole, who had refused to believe in the Family Compact, and had steadily adhered to a policy of peace, was compelled by the popular clamour to declare war in October 1739. The maritime operations which followed were insignificant. Admiral Vernon took Porto Bello, and Anson plundered Payta, but England was distracted by party jealousies and her naval organization had fallen into disorder during the long peace. Luckily for her, Patiño had died in 1736, and the impulse which he had given to the Spanish navy ended with him. But before long the quarrel was absorbed in the great European war which arose about the Austrian succession.

War of the
Austrian
succession

Charles VI had persuaded almost every European power to guarantee the Pragmatic Sanction, but the succession of Maria Theresa to his territories was not in the least facilitated by the paper promises to support her. England was almost the only power that adhered to its engagements. Frederick of Prussia advanced an obsolete claim to Silesia, and France seized the opportunity to humiliate the house of Hapsburg. Spain hastened to join the coalition against the unfortunate heiress. Philip V claimed to represent the Spanish branch of the Hapsburgs, and pleaded the old family agreement by which they were to succeed on the extinction of the Austrian line. There was no possibility of so absurd a claim being recognized, but it opened the prospect of recovering the lost provinces in Italy. Sardinia was gained over by the promise of part of Lombardy. Naples and Sicily were already in the hands of Don Carlos. It seemed hardly possible that Maria Theresa, pressed by enemies on every side, could

successfully defend her Italian territories. A Spanish army under Montemar was embarked in French vessels, and, after evading the English fleet, landed in the Gulf of Genoa in 1741. The first news was discouraging, as Charles Emmanuel of Sardinia, ready like his predecessors to sell his alliance to the highest bidder, had been bought off by Maria Theresa. It was not till 1742 that the campaign began with an advance upon Modena, where the duke had promised his support to Spain. But the Austrians and Sardinians were the first in the field. They expelled the duke of Modena from his territories, and drove Montemar to retreat towards Naples. At the same time the English fleet appeared before Naples, and the threat of an immediate bombardment compelled Don Carlos to promise a strict neutrality during the rest of the war. Count Gages, who was sent to supersede the unsuccessful Montemar, was unable to recover the lost ground, and the first campaign ended without any serious advantage to either side beyond the Austrian occupation of Modena. In 1743 Gages again attempted the invasion of Lombardy, but was defeated at Campo Santo and repulsed. Austria and Sardinia concluded a close alliance in the treaty of Worms (September 1743), which was negotiated by England. France and Spain sought to meet this coalition by renewing the Family Compact at Fontainebleau (October 1743). France undertook to aid in conquering the Milanese for Don Philip, to declare war against England, and not to make peace until Gibraltar, and if possible Minorca too, had been restored to Spain. Don Philip himself was sent with a Spanish army through southern France, but he failed to force a passage through the Alps. The campaign of 1744 was indecisive, but in the next year the great efforts made by Maria Theresa to recover Silesia gave her opponents in Italy an opportunity of which they were not slow to avail themselves. Gages effected a junction at Genoa with the combined French and Spanish troops under Maillebois and Don Philip. Advancing into Piedmont the allies took Tortona, and after occupying Parma and Piacenza they invaded Lombardy. This move effected the desired object of separating the Austrians and Sardinians. Schulenburg hurried off to the defence of his mistress's territories, and the allies at once turned upon Charles Emmanuel and defeated him at Bassignano. The French wished to complete the conquest of Piedmont, but the Spaniards insisted upon renewing the invasion of Lombardy. That province was now entirely undefended, as the Austrians had returned to the assistance of Charles Emmanuel, who detained them by the threat that if he were deserted he would make terms with the allies. One town after another surrendered or was taken, and in December Don Philip entered Milan in triumph. But meanwhile Maria Theresa had ended the Silesian War by the treaty of Dresden, and was thus enabled to send reinforcements into Italy. The tide of success turned with marvellous rapidity. The Spaniards evacuated Lombardy, and were soon driven from all their conquests in Piedmont except Tortona. At Piacenza, to which the Bourbon army had retreated, it was completely defeated by the Austrians.

At this juncture the news arrived from Spain that Ferdinand VI had died on July 9, and had been succeeded by Philip V, the only surviving son of his first marriage. Elizabeth Farnese, "the termagant," as Carlyle calls her, whose ambition had kept Europe embroiled for thirty years, went into retirement at San Ildefonso. This event naturally influenced the war in Italy. It was not likely that the new king, who had never been on good terms with his stepmother, would expend more of his country's blood and treasure to obtain a principality for his half brother. His first act was to supersede Gages by the

marquis of Las Minas, who found the Spanish army at Tortona and hastened to withdraw it from Italy into Savoy, which Don Philip had occupied since 1742. The Austrians at once besieged and captured Genoa, thus cutting off the possibility of a renewed invasion of Italy, except through the well guarded passes of the Alps. From this time the military operations ceased to have any direct importance for Spain, and all interest centred in the negotiations which were carried on at Breda in 1747 and transferred to Aix-la-Chapelle in the next year. The chief obstacle to peace was the demand of a principality for Don Philip, which Ferdinand VI. persisted in as necessary for the honour of Spain. Maria Theresa had already made sacrifices to Prussia and to Sardinia, and resented the idea of ceding any more of her territories. But the persistence of England carried the day, and in the treaty of Aix-la-Chapelle (October 1748) Don Philip obtained Parma, Piacenza, and Guastalla as an hereditary principality, on condition that they should revert to Austria on extinction of his male descendants. This was the sole advantage gained by Spain. Austria retained Lombardy, shorn of the portion promised to Charles Emmanuel, and the commercial and naval ascendancy of England remained unshaken. The recovery of Gibraltar, which at one time Philip V. had confidently expected, was now further off than ever.

Ferdinand VI. was as feeble in health and as averse to business as his father had been, but he was equally obstinate on certain points. He would have nothing to do with the aggressive policy of his stepmother or with the Bourbon schemes for the humiliation of England. His accession broke off the Family Compact, and gave to Spain the unaccustomed boon of thirteen years' peace. His aim was to hold the balance between the rival powers of western Europe, and in this he was aided by the discord between his two ministers, Esenada and Carvalho, of whom the former favoured France and the latter England. When Kaunitz, the Austrian envoy at Versailles, was endeavouring to negotiate an alliance between the Hapsburgs and Bourbons, Ferdinand seized the opportunity to conclude the treaty of Aranjuez, which guaranteed the neutrality of the Italian provinces of the two families. On the outbreak of the Seven Years' War in 1756 great efforts were made to draw Spain into the struggle. France offered Minorca, which had been lost by Byng at the first outbreak of hostilities, and England hastened to make the counter proposition of a cession of Gibraltar. Ferdinand, however, refused both bribes, and maintained his policy of peace till his death in 1759.

Charles
III

This event gave the Spanish crown to Charles III., who had ruled the Two Sicilies since 1735. His accession threatened a speedy reversal of Spanish policy. The new king was a true Bourbon, and naturally inclined to the French alliance. He had an old grudge against England for the treatment he had received in the War of the Austrian Succession. He also owed a debt of gratitude to Maria Theresa for enabling him to transfer the crown of Naples to his third son, whereas by the treaty of Aix-la-Chapelle it ought to have passed to his brother, Philip of Parma. In spite of these motives, he hesitated for two years to take a decisive step. Spain was not prepared for war, and Charles had never cordially approved the change of policy at Versailles which had united France with its old rival Austria. But the rapid successes of England under Pitt's administration, and the danger of a vast extension of the maritime and colonial ascendancy of that country, soon overcame his scruples. In 1761 the third Family Compact was concluded, and Spain undertook to give active assistance to France unless peace were concluded within a year. Pitt, suspecting the existence

of this agreement, proposed an immediate declaration of war against Spain, but he failed to convince his cabinet and resigned. His successors, however, were driven to adopt his policy, and in January 1762 hostilities commenced between the two countries. But Spain only entered the war to share the disasters which France had already begun to suffer. An invasion of Portugal, which had been regarded as a defenceless prey, was foiled by English assistance, and the English fleet captured Martinique and Havana. The Bourbon powers found it necessary to implore peace, and it was fortunate for them that the English government had passed into the hands of Butte, who was eager to diminish the influence of Pitt by terminating the war. By the treaty of Paris (February 1763) England recovered Minorca, extended its colonies in every direction at the expense of France, and rejected all the demands which Charles III. had advanced on behalf of Spain.

In spite of the treaty Charles III.'s foreign policy continued to be guided by jealousy of England, and he clung to the French alliance as the only means by which he could avenge his recent humiliation. In this he was encouraged by his foreign minister, Grimaldi, who was so devoted to France that Choiseul declared himself to be more powerful at Madrid than at Versailles. In 1770 a dispute about the Falkland Islands, from which the English settlers had been expelled by a Spanish force, would probably have led to a renewal of war if a domestic intrigue had not succeeded at this juncture in overthrowing Choiseul. For the next few years a marked coolness grew up between France and Spain, which was increased when Louis XVI. disappointed the hopes that had been formed of his accession and left Choiseul in retirement. Grimaldi, chagrined at the failure of an alliance on which all his schemes were based, resigned office in 1777 and was succeeded by Count Florida Blanca, one of the most distinguished of the able ministers who ruled Spain during this period. The change of ministers made no difference to the policy of Charles III., whose obstinacy was in no way inferior to that of his predecessors. For many years Spain and Portugal had been engaged in disputes about the frontiers of their territories in South America, disputes which were rendered more bitter by the arrogance of Pombal, the Portuguese minister. The death of Joseph I. in 1777 and the consequent dismissal of Pombal enabled Florida Blanca to negotiate the treaty of San Ildefonso, by which Sacramento and the navigation of the Rio de la Plata were ceded to Spain, and a definite boundary was drawn between Brazil and Paraguay on the one side and Peru on the other. This was followed in March 1778 by the conclusion of a perpetual alliance at the Pardo, by which Portugal was attached to the interests of the Bourbon states. These treaties, which Florida Blanca regarded as among the most signal successes of his ministry, came very opportunely to enable Charles III. to resume the schemes that had lain in abeyance since 1763. England was involved in a desperate struggle with the revolted colonies of North America, and this offered the Bourbons the long-desired opportunity for revenge. In 1778 France entered into close alliance with the colonists, and in the next year Spain followed her example. Everything seemed to favour the allies. The Northern powers, irritated by the high-handed way in which England had asserted and exercised her maritime supremacy, formed the "armed neutrality" under the lead of Catherine II. ally of England, was involved in the general coalition. England, which had failed single handed to coerce its own subjects, was now face to face with the whole maritime power of Europe, and was also hampered by domestic and

Irish troubles Spain succeeded in capturing Minorca and laid close siege to Gibraltar. Many of the West-Indian islands were captured from the English, and the surrender of Cornwallis at Yorktown destroyed the last hope of restoring American dependence. The most confident hopes were entertained of stripping England of the great bulk of its colonial possessions. But in 1782 the tide of success turned. Rodney, by the novel manoeuvre of breaking the line, destroyed the French fleet in the West Indies, while the heroic defence of General Elliott and the opportune arrival of supplies under the convoy of Lord Howe saved Gibraltar from overwhelming odds. The want of unanimity among the allies, each of whom thought only of its own interests, hastened the conclusion of peace in 1783. The treaty of Versailles, by which Spain kept Minorca and obtained the Floridas, was the most honourable which that country had concluded since Cateau Cambresis. But the failure to recover Gibraltar was a bitter disappointment to Charles III., who continued till his death (December 14, 1788) to cherish the scheme of renewing the war, though the growing disorders in France made it more and more certain that he could no longer rely upon the assistance of that country.

Revival
of Spain
in the
18th
century

The reigns of the first three Bourbon kings form a period of great importance in Spanish history. At the end of the 17th century Spain appeared to be a lifeless corpse, over which the other powers of Europe could contend at will. In the 18th century men were astounded to see that country rise with renewed vigour to play once more an independent part on the international stage. This revival was due in the first place to the change of dynasty. Another Hapsburg would probably have continued the obsolete policy of his predecessors. The accession of the Bourbons introduced into Spain the methods and ideas of government which had raised France to greatness under Richelieu, Mazarin, and Colbert. The two great problems to be grappled with were the profound depression of trade and agriculture and the fatal wealth and ascendancy of the church. Philip V., feeble as he was personally, began the movement in advance even during the Succession War. The abolition of the old provincial independence rendered possible a more regular and centralized government, an increase of the revenue, and the removal of the old impediments to trade between the various provinces. The French officers who accompanied the king gave a new organization and new tactics to the Spanish army. Under the influence of the princess Orsini Philip seemed inclined to attack even the prescriptive privileges of the clergy. His marriage with Elizabeth Farnese saved the hierarchy and diverted his attention to wars of aggrandizement. But these wars were directed by purely political motives, the old Hapsburg idea of a religious propaganda was for ever abandoned. And even during the war the task of internal reform was hindered rather than neglected. The efforts of Alberoni and Patiño gave Spain a navy more powerful than that of Philip II. The conquest of the Two Sicilies and the acquisition of Parma, though they brought little direct advantage to Spain, yet gave conclusive evidence that the old lethargy had been shaken off and that the country was capable of exertions and sacrifices which had long appeared impossible. The period of peace under Ferdinand VI was an inestimable boon to Spain. Taxation was lightened, production was facilitated by the removal of the most crushing burdens, yet at the same time the revenue improved and the chronic deficit of previous reigns was replaced by a surplus. And this prince took a step which no one would have expected from him. The concordat of 1753 was the first vindication of the political interests of Spain against the pretensions of Rome. The crown

asserted its right to appoint to all important benefices, and the number of papal presentations was reduced from twelve thousand to fifty-two. The revenue derived by the crown from Spain was proportionately diminished, and the clergy were compelled to recognize their obligations as members of the body politic. This measure was followed by an edict that henceforth papal bulls should not be obeyed until they had received the royal sanction.

The work of reform, thus tentatively commenced under Philip V and Ferdinand VI, was carried still further by Charles III., whose reign is regarded with more pride by the Spaniards than any other since that of Philip II. Charles had served an apprenticeship in the art of government in Naples, where, with the help of his minister Tanucci, he had successfully grappled with evils similar to those from which Spain was suffering. He would have been a prince quite after the heart of the 18th century if he had not retained too large a share of the superstition of his family. He shared to the full that conception of the rights and duties of monarchy which inspired the reforms of Frederick the Great and Joseph II., and his allegiance to the church was fortunately counterbalanced by his desire for absolutism. His greatest work, the expulsion of the Jesuits, would never have been carried out if he had not been persuaded of its political necessity. The order had already been driven by Pombal from Portugal and by Choiseul from France, when Charles III. was convinced that a riot in Madrid, provoked by the financial measures of Squillaci, had been promoted by the Jesuits. This conviction overpowered all scruples, the fathers were promptly removed from the country, and Spain joined the other Bourbon courts in demanding that suppression of the order which was finally decreed by Clement XIV. in 1773. The Rubicon once crossed, Charles's ministers urged him on in the path of ecclesiastical reform. The increase of lands in mortmain was restricted, the number of monasteries was diminished, and the Inquisition was compelled to moderate its procedure and to subordinate its independence to the royal will. For the papal jurisdiction was substituted a national court, the *Rota*, established at Madrid.

These measures, of which the importance in a country like Spain can hardly be over-estimated, were accompanied by others no less notable for the development of trade and agriculture. The colonial trade was freed from the old restriction which compelled it to pass through Cadiz, and other ports were opened for its reception. Native manufactures were encouraged in every way, and a famous ordinance in 1773 endeavoured to remove the old prejudice against trade by declaring that the engaging in industrial occupations should not involve any loss of rank or its privileges. Internal communication was facilitated by the construction of canals. Agriculture was revived by the removal of the old prohibition against enclosures,—so long maintained by the selfish influence of the *Mesta*,—by the planting of trees in the arid deserts of central Spain, and by the rapid growth of population, which rose in the course of the century from 5,700,000 to 10,541,000. These measures, which are only selected from a large number tending in the same direction, are to be credited to three ministers, whose names reflect its chief lustre upon Charles III.'s reign. D'Aranda, who succeeded the Italian Squillaci as finance minister, was an Aragonese noble who had imbibed the spirit of philosophical speculation from France. He was the first layman who presided in the council of Castile, and he introduced into the Spanish administration a liberal tendency quite opposed to the traditions of the country. His views, however, were not congenial to the king, and, after completing his work with regard to the Jesuits and the Inquisition, he retired to the

embassy in Paris and was succeeded by Campomanes. The latter was not only a distinguished statesman but also one of the foremost representatives of Spanish literature. He was one of the earliest students of political economy, and many of the most enlightened measures for the relief and encouragement of trade are to be assigned to him. But his administration, which aimed at educating the people to a share in political life, was almost as alien to the wishes of Charles III. as the liberal and anti-clerical schemes of D'Aranda. A far more congenial minister was found in Florida Blanca, whose aim was to promote the material interests of Spain by the supervision of an internal despotism, who stopped the attack on the church when its subordination was secured, who supported the economic reforms of Campomanes, but would only carry them out by a rigid bureaucracy, and who conciliated the king by falling in with his foreign policy even when it conflicted with the national welfare.

Meritorious as Charles III's reforms were, it would give a false impression to represent them as completely successful. The regeneration of Spain was by no means accomplished, and many of the abuses which had been growing for centuries survived the attempt to effect their annihilation. One of the chief causes of this failure was the corruption and ignorance of the lower officials. The reforming impulse was confined to the educated classes, and made little impression upon the bulk of the people. It was of little use to devise the most enlightened measures when there was no efficient machinery to carry them out. Many of the most promising reforms remained mere paper schemes. The methods employed, too, were not always the best calculated to obtain their end. The state took too much upon itself, and attempted to discharge functions which would have been better left to local enterprise. Roads were constructed on a magnificent scale, but only too often in directions where they were not wanted, and they remained almost unused. Thus the debt was increased without any improvement of the revenue. The return of Charles III. to a military policy imposed serious burdens upon the country, and it would have been better to have prolonged the peace of Ferdinand VI's reign, inglorious as it appeared to an ambitious king. Undoubtedly a great advance was made, but equal exertions would have produced a greater result in any other country. The population of Spain remained to a great extent sunk in sloth and superstition. Much might be hoped from a steady persistence in ameliorative measures, but unfortunately the work of reform was interrupted just at the moment when success appeared to be within reach.

Charles
IV

The death of Charles III. and the accession of Charles IV were contemporary with the outbreak of the French Revolution, which was destined to exercise a decisive influence over the fortunes of the adjacent peninsula. Florida Blanca, who continued to hold office during the first three years of the new reign, found it impossible to continue his policy. The revival of Spain could only be effected by the restoration of its naval and colonial ascendancy at the expense of England, and for the carrying out of this scheme the support of France was imperatively necessary. But the French alliance rested upon the relationship between the two branches of the house of Bourbon, and the Family Compact ceased to exist when Louis XVI. was deprived of power by his subjects. Of this conclusive evidence was given in 1791. Some English merchants founded a settlement at Nootka Sound on the west coast of America, which provoked an indignant protest from Spain. But the French national assembly refused to send any assistance, and Florida Blanca was compelled to conclude a humiliating treaty and to give up

all hope of opposing the progress of England. This failure was attributed by the minister to the Revolution, of which he became the uncompromising opponent. The reforms of Charles III's reign were abandoned, all liberal tendencies in Spain were suppressed, and the Government set itself to restore the old lethargy under absolute rule from which the country had been gradually awakened. The movement of reform had made so little progress among the mass of the people that reaction was really easier than progress. But Florida Blanca was not content with suppressing liberalism in Spain, he was eager to avenge his disappointment by crushing the Revolution in France. He opened negotiations with the emigrants, urged the European powers to a crusade on behalf of legitimacy, and paraded the devotion of Charles IV. to the head of his family. This bellicose policy, however, brought him into collision with the queen, Maria Louisa of Parma, a woman whose real abilities were perverted to the gratification of sensual lusts, was unwilling to allow the minister to share her ascendancy over the feeble mind of her husband, and she feared that the outbreak of war would diminish the revenues which she squandered in self-indulgence. She had already removed from the ministry Campomanes and other supporters of Florida Blanca, and had compelled the latter to restrict himself to the single department of foreign affairs. Early in 1792 she completed her task by inducing Charles IV. to banish Florida Blanca to Murcia, and his place was entrusted to the veteran D'Aranda. But the new minister found that he held office only at the favour of the queen, and that this had to be purchased by a disgraceful servility to her paramour, Emanuel Godoy. Spain withdrew from the projected coalition against France, and sought to maintain an attitude of neutrality, which alienated the other powers, while it failed to conciliate the republic. The repressive measures of Florida Blanca were withdrawn, society and the press regained their freedom, and no opposition was offered to the propaganda of French ideas. D'Aranda's policy might have been successful if it had been adopted earlier, but the time for temporizing was now past, and it was necessary for Spain to choose one side or the other. But the decision was not allowed to rest with the man who had always shown a sympathy with the revolutionary principles. In November 1792 the queen felt herself strong enough to carry out the scheme which she had been long maturing. D'Aranda was dismissed, and the office of first minister was entrusted to Godoy, who had recently received the title of duke of Alcudia. Godoy, who was at once the queen's lover and the personal favourite of the king, had had no education for the part which he was called upon to play. Though endowed with a natural quickness of parts and a capacity for intrigue, he had no habits of application, no experience of the routine of office, and above all no settled policy. His appointment was regarded with jealousy by the *grandees* of Spain, while his undisguised relations with the queen outraged the moral feelings of the best part of the nation. Luckily for Godoy, the course to be pursued was decided for him. The execution of Louis XVI. (January 21, 1793) made a profound impression in a country where loyalty was a superstition. Charles IV. was roused to demand vengeance for the insult to his family, and from one end of Spain to the other a cry resounded for immediate war with the impious rebels who had shed the blood of an anointed king. Godoy had nothing to do but to follow the national impulse, and Spain became a member of the first coalition against France. Everything seemed to promise a rapid and complete success. The number of volunteers who offered their services rendered conscription unnecessary, and the southern provinces of France were so preponder-

attingly royalist that they were ready to welcome the Spaniards as deliverers. These advantages, however, were nullified by the shameful incompetence and carelessness of the Government. The troops were left without supplies; no plan of combined action was imposed upon the commanders, and each regiment was left to act of its own will. The military action of Spain provoked the contempt of Europe. The two campaigns of 1793 and 1794 were one long catalogue of failures. The bravery of the soldiers was rendered useless by the incapacity of their officers, and the unadministration of the central Government excited such disgust that an outbreak of revolutionary disturbances in Spain itself seemed more than possible. Instead of reducing the southern provinces of France, the Spaniards were driven from the strong fortresses that guarded the Pyrenees, and the French advanced almost to the Ebro. And at the same time the English, the hated rivals of Spain, were utilizing the war to extend their colonial power and were establishing more firmly that maritime supremacy which the Spanish Government had been struggling for almost a century to overthrow. Under the circumstances it is no wonder that the queen and Godoy hastened to follow the example set by Prussia, and concluded the treaty of Basel with France. The terms were unexpectedly favourable. Spain purchased the evacuation of her territories and fortresses by the cession of her share of St Domingo, which had little but a sentimental value as the first discovery of Columbus, and which had already been occupied by the English. So great was the joy overtaken in Madrid that popular acclamation greeted the bestowal upon Godoy of the title of "Prince of the Peace." But the moderation of the treaty was only a flimsy disguise of the disgrace that it involved. Spain found herself tied hand and foot to the French republic. Godoy had to satisfy his allies by the encouragement of reforms which both he and his mistress loathed, and in 1796 the veil was removed by the conclusion of the treaty of San Ildefonso. This was a virtual renewal of the Family Compact of 1761, but with far more disadvantageous terms to Spain. Each power was pledged to assist the other in case of war with twenty-five ships, 18,000 infantry, and 6000 cavalry. The real object of the treaty, which was to involve Spain in the war against England, was cynically avowed in the eighteenth article, by which, during the present war, the Spanish obligations were only to apply to the quarrel between England and France. A scheme was prepared for a joint attack on the English coast, but it was foiled by the battle of St Vincent, in which Jervis and Nelson forced the Spanish fleet to retire to Cadiz. This defeat was the more disastrous because it cut off the connexion with the colonies and thus deprived Spain of the revenues derived from that quarter. The finances, already exhausted by extravagance and maladministration, were in no condition to meet the expenses of a naval war. England seized the opportunity to punish Spain for its conduct in the American War by encouraging discontent in the Spanish colonies, and in the Peninsula itself both nobles and people were bitterly hostile to the queen and her favourite. It was in vain that Godoy sought to secure the friendship of the reforming party by giving office to two of its most prominent members, Jovellanos and Saavedra. Spanish pride and bigotry were offended by the French occupation of Rome and the creation of a republic in the place of the papal government. The treatment of the duke of Parma by the Directory was keenly resented by the queen. Godoy found himself between two parties, the liberals and the ultramontanes, who agreed only in hatred of himself. At the same time the Directory, whose mistrust was excited by his attitude

in the question of Parma, insisted upon his dismissal. Charles IV could not venture to refuse a demand from France, the queen was alienated by Godoy's notorious infidelities, and in March 1798 he was compelled to resign his office. But he did not forfeit his hold on the king's favour, and he only waited for a favourable opportunity to emerge from his retirement.

Godoy's office was entrusted to Saavedra, but the reformers did not obtain the advantages which they expected from the change. Jovellanos was compelled in August to retire on account of ill health,—the result, it was rumoured, of attempts on the part of his opponents to poison him. His place was taken by Caballero, an ardent opponent of reform, who restored all the abuses of the old bureaucratic administration and pandored to the most bigoted prejudices of the clergy and the court. The ministry was hopelessly divided, and the policy of the country was directed by the basest and most paltry intrigues. The only advantage which Spain enjoyed at this period was comparative independence of France. The military plans of the Directory were unsuccessful during the absence of their greatest general in Egypt, and the second coalition gained successes in 1799 which had seemed impossible since 1793. But the return of Bonaparte, followed as it was by the fall of the Directory and the establishment of the Consulate, commenced a new epoch for Spain. As soon as the First Consul had time to turn his attention to the Peninsula, he determined to restore Godoy, who had already regained the affection of the queen, and to make him the tool of his policy. Maria Louisa was easily gained over by playing on her devotion to the house of Parma, and on October 1, 1800, a secret treaty was concluded at San Ildefonso. Spain undertook to cede Louisiana and to aid France in all her wars, while Bonaparte promised to raise the duke of Parma to the rank of king and to increase his territories by the addition either of Tuscany or of the Roman Legations. This was followed by Godoy's return to power, though he left the department of foreign affairs to a subordinate. Spain was now more servile to France than ever, and in 1801 was compelled to attack Portugal in the French interests. Bonaparte was indignant against Portugal, partly because its fleet had aided his enemies in Egypt, and partly because its harbours offered great naval advantages to the English. The Spanish invasion, which was commanded by Godoy in person, met with no resistance, and the prince ventured to conclude a peace on his own authority by which Portugal promised to observe a strict neutrality on condition that its territories were left undiminished. But Bonaparte resented this show of independence, and compelled Charles IV to refuse his ratification of the treaty. Portugal had to submit to far harsher terms, and could only purchase peace by the cession of territory in Guiana, by a disadvantageous treaty of commerce, and by a payment of twenty-five millions of francs. This insult to his ally Bonaparte followed up by others. In the preliminary treaty with England he ceded the Spanish colony of Trinidad without even consulting the court of Madrid, while he sold Louisiana to the United States in spite of his promise not to alienate it except to Spain. For these humiliations Spain had to console itself with the empty honour of being the first signatory of the treaty of Amiens.

For nearly three years Spain was allowed to remain at peace. Its finances were partially revived by the restoration of free intercourse with the colonies and by the payment of the supplies which had been withheld for the last six years. But the administration was as incompetent and misdirected as ever. Godoy, since his return to office, had abandoned all connexion with the reforming party

and had thrown himself into the reactionary policy of Caballero. The Spanish church was once more placed in strict subjection to the Roman see, from which for a short time it had been freed. But the worst evil lay in the undisguised domination of France, which the Government was wholly incapable of shaking off. As soon as Bonaparte saw himself involved in a new war with England, he turned to Spain for assistance and extorted a new treaty (October 9, 1803), which was still more burdensome than that of 1796. Spain had to pay a monthly subsidy of six million francs, and to pledge itself to enforce a strict neutrality upon Portugal. Thus the country was involved in a new and still more disastrous war with England. The last remnants of its maritime power were shattered in the battles of Cape Finisterre and Trafalgar, and the English seized Buenos Ayres. The popular hatred of Godoy was roused to passion by these disasters, and many competent observers believed that Spain stood on the brink of revolution. At the head of the opposition was the crown prince Ferdinand, as insignificant as his rival, but endowed with all good qualities by the credulous favour of the people. To maintain himself against his domestic enemies Godoy turned to France, where Bonaparte, now the emperor Napoleon I., was irritated by the crown prince's marriage with a daughter of the king of Naples. The court quarrels at Madrid were fomented from Paris in order to complete the subordination of Spain. Napoleon was at this time eager to humble England by excluding it from all trade with Europe. The only country which had not accepted his "continental system" was Portugal, and he determined to reduce that kingdom by force. It was not difficult to bribe Godoy, who was conscious that his position could not be maintained after the death of Charles IV. In October 1807 Spain accepted the treaty of Fontainebleau, which arranged a partition of Portugal into three parts. The northern provinces were to be given to the young king of Etruria, who was to purchase them by the cession of Tuscany. In the south a principality was to be carved out for Godoy himself. The central district was to be kept in pledge by France until the conclusion of a general peace. The treaty was hardly concluded when a French army under Junot marched through Spain to Portugal, and the royal family of that country fled to Brazil. But Spain was destined to share the same fate as its neighbour. The crown prince, whose wife had died in 1806, determined to imitate his rival by bidding for French support. He entered into secret relations with Beauharnais, Napoleon's envoy at Madrid, and went so far as to demand the hand of a Bonaparte princess. Godoy, who discovered the intrigue, induced Charles IV. to order his son's arrest. Napoleon at once seized the opportunity to make himself absolute master of Spain, and ordered French troops to cross the Pyrenees in support of the prince. This act terrified Godoy into a reconciliation with his opponents, but the French invasion was not delayed by the removal of its pretext. Charles IV. and his minister, conscious that they could expect no support from the people, determined on flight. The news of this intention, however, excited a popular rising in Madrid, and the king was compelled to abdicate in favour of his son. Murat, however, who commanded the French, refused to be turned aside by this change of circumstances. He obtained from Charles IV. a declaration that his abdication had been involuntary, and occupied Madrid (March 23, 1808). Meanwhile Napoleon advanced to the frontier, and Ferdinand was lured by French agents to an interview with the emperor at Bayonne. There he was confronted with his parents and Godoy, and was intimidated into restoring the crown to his father, who at once made a

second abdication. Napoleon now divulged the real intention of his actions, and the crown of Spain was formally conferred upon his brother Joseph Bonaparte, who two years before had been made king of Naples. Joseph Bonaparte

But Spanish loyalty was too profound to be daunted even by the awe-inspiring power of the French emperor. For the first time Napoleon found himself confronted, not by terrified and selfish rulers, but by an infuriated people. The rising in Spain commenced the popular movement which ultimately proved fatal to his power. At first he treated the novel phenomenon with contempt, and thought it sufficient to send his less prominent generals against the rebels. Madrid was taken without difficulty, but the capital was absolutely devoid of military importance, and the Spaniards showed great capacity for the guerrilla warfare in the provinces. The French were repulsed from Valencia, and Dupont, who had advanced into the heart of Andalusia, was compelled to retreat and ultimately to capitulate with all his forces at Baylen (July 10). The Spaniards now advanced upon Madrid and drove Joseph from the capital, which he had just entered. Unfortunately the insurgents displayed less political ability than military courage. The government was entrusted in Ferdinand's name to a central junta of thirty-four members, a number which was far too large for the conduct of executive business. Napoleon's arrival in Spain was enough to restore victory to the French. In less than a week the Spanish army was broken through and scattered, and Napoleon restored his brother in Madrid. Sir John Moore, who had advanced with an English army to the relief of the capital, retired when he found he was too late, and an obstinate battle, in which the gallant general lost his life, had to be fought before the troops could secure their embarkation at Coruña. Napoleon, thinking the work accomplished, had quitted the Peninsula, and Soult and Victor were left to complete the reduction of the provinces. The capture of Seville resulted in the dissolution of the central junta, and the Peninsula was only saved from final submission by the obstinate resistance of Wellington in Portugal and by dissensions among the French. The marshals were jealous of each other, and Napoleon's plans were not approved by his brother Joseph, who wished to restore peace and order among his subjects in the hope of ruling an independent nation, while Napoleon was determined to annex Spain to his own overgrown empire. So far did these disputes go that Joseph resigned his crown, and was with difficulty induced to resume it. Meanwhile Cadiz became the capital of what was left of independent Spain, and there the cortes met in 1810 for the purpose of drawing up a new constitution. The fall of the old monarchy and the exigencies of self-defence had given to the reforming party an ascendancy which they had never before possessed. In the constitution which was promulgated early in 1812 the principles of the French constituent assembly were closely followed. The Inquisition had already perished, and the last relics of the old autocratic government shared its fate. Supreme legislative power was placed in the hands of a single national assembly, and effective checks were devised to restrict the power of the monarchy whenever it should be revived. The freedom of the press was established, and the property of the clergy was confiscated to defray the expenses of the war. The great defect of the constitution was that it was the work of one party, to which circumstances had given a temporary supremacy, and it failed to command the support of the united nation. The nobles and priests were bitterly hostile, and the latter had more influence in Spain than in any European country except Ireland.

The restoration of Spanish independence could hardly

have been accomplished without the assistance of England. Wellington had already made two attempts to advance from Portugal into the adjacent kingdom, but had been foiled by superior forces. In 1812 he determined on a great effort. He secured his base of operations by the capture of Ciudad Rodrigo and Badajoz, and at Salamanca he completely routed the opposing army of Marmont. This victory enabled the English general to enter Madrid (August 12), and Joseph retreated to Valencia. But further advance was prevented by the concentration of the French forces in the east, and Wellington found it advisable to retire for the third time to winter-quarters on the Portuguese frontier. It was during this winter that Napoleon suffered his first and greatest reverse in the retreat from Moscow and the destruction of his grand army. This was the signal for the outbreak of the "war of liberation" in Germany, and French troops had to be withdrawn from Spain to central Europe. For the first time Wellington found himself opposed by fairly equal forces. In the spring of 1813 he advanced from Ciudad Rodrigo and defeated Jourdan at Vittoria, the battle which finally decided the Peninsular War. Joseph retired altogether from his kingdom, and Wellington, eager to take his part in the great European contest, fought his way through the Pyrenees into France. Napoleon, who had suffered a crushing defeat at Leipzig, hastened to recognize the impossibility of retaining Spain by releasing Ferdinand VII, who returned to Madrid in March 1814.

Ferdinand
VII

After the convulsions it had endured Spain required a period of firm but conciliatory government, but the ill-fate of the country gave the throne at this crisis to the worst of her Bourbon kings. Ferdinand VII had never possessed the good qualities which popular credulity had assigned to him, and he had learnt nothing in his four years' captivity except an aptitude for lying and intrigue. He had no conception of the duties of a ruler, his public conduct was regulated by pride and superstition, and his private life was stained by the grossest sensual indulgence. Spain was still governed under the constitution of 1812, but the king's first act was to dissolve the cortes and to abrogate the constitution, promising, however, to grant a new one in its place. But no sooner was he established on the throne, and conscious of the strong reaction in favour of the monarchy, than he threw his promises to the wind and set himself to restore the old absolutism with all its worst abuses. The nobles recovered their privileges and their exemption from taxes, the monasteries were restored, the Inquisition resumed its activity, and the Jesuits returned to Spain. The liberals were ruthlessly persecuted, together with all who had acknowledged Joseph Bonaparte. A *camarilla* of worthless courtiers and priests conducted the government, and urged the king to fresh acts of revolutionary violence. For six years Spain groaned under a royalist "reign of terror," and isolated revolts only served as the occasion for fresh cruelties. The finances were squandered in futile expeditions to recover the South American colonies, which had taken advantage of Napoleon's conquest of Spain to establish their independence. In his straits for money Ferdinand ventured to outrage national sentiment by selling Florida to the United States in 1819. Discontent found expression in the formation of secret societies, which were especially powerful among the neglected and ill-paid soldiers. At last, in 1820, Riego and Quiroga, two officers of an expedition which had been prepared for South America, raised the standard of revolt in Cadiz. Ferdinand and his advisers proved as incapable as they were tyrannical, and their feeble irresolution enabled the movement to spread over the whole country. In March the king gave way and accepted the constitution of 1812.

The royalists or *señores*, as they were called, were dismissed from office and their places taken by liberals. The cortes met in July, and at once proceeded to dissolve the monasteries and the Inquisition, to confiscate the clerical tithes, to abolish entails, and to secure the freedom of the press and of popular meetings. Great results might have been achieved if the moderate party, under Martinez de la Rosa, had been able to grapple with the task of suppressing disorder and establishing a permanent constitution. But this was the last thing which the king desired, and the moderates were defeated by a factious combination of the *señores* and the radicals. Risings took place among the loyal and bigoted peasants of the provinces, and their suppression contributed to the victory of the extreme party, which seemed to be secured in 1822 by the election of Riego as president of the cortes.

But Spain was not allowed to work out its own salvation. Europe was dominated at this time by the Holy Alliance, which disguised a resolution to repress popular liberties and to maintain despotism under a pretended zeal for piety, justice, and brotherly love. At the congress of Verona (October 1822) France, Austria, Russia, and Prussia agreed upon armed intervention in Spain, in spite of the protest of Canning on the part of England. Spain was to be called upon to alter her constitution and to grant greater liberty to the king, and if an unsatisfactory answer were received France was authorized to take active measures. The demand was unhesitatingly refused, and a French army, 100,000 strong, at once entered Spain under the duke of Angoulême (April 1823). No effective resistance was made, and Madrid was entered by the invaders (May 23). The cortes, however, had carried off the king to Seville, whence they again retreated to Cadiz. The bombardment of that city terminated the revolution and Ferdinand was released (October 1). His first act was to revoke everything that had been done since 1819. The Inquisition was not restored, but the secular tribunals took a terrible revenge upon the leaders of the rebellion. The protest of the duke of Angoulême against these cruelties was unheeded. Even the fear of revolt, the last check upon despotism, was removed by the presence of the French army, which remained in Spain till 1827. But Spain had to pay for the restoration of the royal absolutism, as Canning backed up his protest against the intervention of France by acknowledging the independence of the Spanish colonies.

Ferdinand VII was enabled to finish his worthless and disastrous reign in comparative peace. In 1829 he married a fourth wife, Maria Christina of Naples, and at the same time he issued a "Pragmatic Sanction" abolishing the Salic law in Spain. No one expected any practical results from this edict, but a formal protest was made against it by the king's brothers, Carlos and Francisco, and also by the French and Neapolitan Bourbons. In the next year, however, the queen gave birth to a daughter, Isabella, who was proclaimed as queen on her father's death in 1833, while her mother undertook the office of regent. Don Carlos at once asserted his intention of maintaining the Salic law, and rallied round him all the supporters of absolutism, especially the inhabitants of the Basque Provinces. Christina was compelled to rely upon the liberals, and to conciliate them by the grant of a constitution, the *estatuto real*, which established two chambers chosen by indirect election. But this constitution, drawn up under the influence of Louis Philippe of France, failed to satisfy the advanced liberals, and the Christians split into two parties, the *moderados* and *progresistas*. In 1836 the latter party extorted from the regent the revival of the constitution of 1812. All this time the Government was involved in a desperate struggle.

with the Carlists, who at first gained considerable successes under Zumalacarregui and Cabrera. But the death of Zumalacarregui in 1835 and the support of France and England ultimately gave the regent the upper hand, and in 1839 her general, Espartero, forced the Basque Provinces to submit to Isabella. Don Carlos renounced his claims in favour of his eldest son, another Carlos, and retired to Trieste, where he died in 1855. Christina now tried to sever herself from the *progresistas*, and to govern with the help of the moderate party who enjoyed the patronage of Louis Philippe. But England, jealous of French influence at Madrid, threw the weight of her influence on to the side of the radicals, who found a powerful leader in Espartero. In 1840 Christina had to retire to France, and Espartero was recognized as regent by the cortes. But his elevation was resented by the other officers, while his subservience to England made him unpopular, and in 1843 he also had to go into exile. Isabella was now declared of age. Christina returned to Madrid, and the *moderados* under Narvaez obtained complete control over the government. This was a great victory for France, and Louis Philippe abused his success by negotiating the infamous "Spanish marriages." A husband was found for Isabella in her cousin, Francis of Assis, whose recommendation in French eyes was the improbability of his begetting children. On the same day the queen's sister, Maria Louisa, was married to Louis Philippe's son, the duke of Montpensier. By this means it was hoped to secure the reversion of the Spanish throne for the house of Orleans. The scheme recoiled on the heads of those who framed it. The alienation of England gave a fatal impulse to the fall of Louis Philippe, while the subsequent birth of children to Isabella deprived the Montpensier marriage of all importance.

Spanish history during the reign of Isabella II. presents a dismal picture of faction and intrigue. The queen herself sought compensation for her unhappy marriage in sensual indulgence, and tried to cover the dissoluteness of her private life by a superstitious devotion to religion and by throwing her influence on to the side of the clerical and reactionary party. Every now and then the *progresistas* and *moderados* forced themselves into office, but their mutual jealousy prevented them from acquiring any permanent hold upon the government. In 1866 Isabella was induced to take vigorous measures against the liberal opposition. Narvaez was appointed chief minister, and the most prominent liberals, Serrano, Prim, and O'Donnell, had to seek safety in exile. The cortes were dissolved, and many of the deputies were transported to the Canary Islands. The ascendancy of the court party was maintained by a rigorous persecution, which was continued after Narvaez's death (April 1868) by Gonzales Bravo. Common dangers succeeded at last in combining the various sections of the liberals for mutual defence, and the people, disgusted by the scandals of the court and the contemptible *camarilla* which surrounded the queen, rallied to their side. In September 1868 Serrano and Prim returned to Spain, where they raised the standard

of revolt and offered the people the bribe of universal suffrage. The revolution was speedily accomplished, and Isabella fled to France, but the successful rebels were at once confronted with the difficulty of finding a successor for her. During the interregnum Serrano undertook the regency, and the cortes drew up a new constitution, by which an hereditary king was to rule in conjunction with a senate and a popular chamber. As no one of the Bourbon candidates for the throne was acceptable, it became necessary to look round for some foreign prince. The offer of the crown to Leopold of Hohenzollern-Sigmaringen excited the jealousy of France, and gave Napoleon III. the opportunity of picking a quarrel, which proved fatal to himself, with the rising state of Prussia. At last a king was found (1870) in Amadeus of Aosta, the second son of Victor Emmanuel, who made an honest effort to discharge the difficult office of a constitutional king in a country which was hardly fitted for constitutional government. But he found the task too hard and too distasteful, and resigned in 1873. A provisional republic was now formed, of which Castelar was the guiding spirit. But the Spaniards, trained to regard monarchy with superstitious reverence, had no sympathy with republican institutions. Don Carlos seized the opportunity to revive the claim of inalienable male succession, and raised the standard of revolt in the Basque Provinces, where his name was still a power. The disorders of the democrats and the approach of civil war threw the responsibility of government upon the army. The cortes were dissolved by a military *coup d'état*, Castelar threw up his office in disgust, and the administration was undertaken by a committee of officers. Anarchy was suppressed with a strong hand, but it was obvious that order could only be restored by reviving the monarchy. Foreign princes were no longer thought of, and the crown was offered to and accepted by Alfonso XII., the young son of the exiled Isabella (1874). His first task was to terminate the Carlist War, which still continued in the north, and this was successfully accomplished in 1876. Time was required to restore the prosperity of Spain under a peaceful and orderly government and to consolidate by prescription the authority of the restored dynasty. Unfortunately a premature death carried off Alfonso XII. in 1885, before he could complete the work which circumstances laid upon him. The regency was entrusted to his widow, Christina of Austria, and the birth of a posthumous son (May 17, 1886), who is now the titular king of Spain, has excited a feeling of pitying loyalty which may help to secure the Bourbon dynasty in the last kingdom which is left to it.

PART III.—LANGUAGE.

The Iberian Peninsula is not a linguistic unity. Not to speak of the Basque, which still forms an island of some importance in the north-west, three Romance languages share this extensive territory—(1) Portuguese Galician, spoken in Portugal, Galicia, and a small portion of the province of Leon, (2) Castilian, covering about two-thirds of the Peninsula in the north, centre, and south, (3) Catalan, occupying a long strip of territory to the east and south-east.

These three varieties of the *Romana Rustica* are marked

off from one another much more distinctly than is the case with, say, the Romance dialects of Italy, they do not interpenetrate one another, but where the one ends the other begins. It has only been possible to establish at the points of junction of two linguistic regions the existence of certain mixed jargons in which certain forms of each language are intermingled, but these jargons, called into existence for the necessities of social relations by bilinguals, have an essentially individualistic and artificial character. The special development of the vulgar

Latin tongue in Spain, and the formation of the three linguistic types just enumerated, were promoted by the peculiar political circumstances. From the 9th century onwards Spain was slowly recaptured from the Mohammedans, and the Latin spoken by the Christians who had taken refuge on the slopes of the Pyrenees was slowly carried back to the centre and ultimately to the south of the Peninsula, whence it had been driven by the Arab invasion. Medieval Spain divides itself into three *conquistas*—that of Castile (much the most considerable), that of Portugal, and that of Aragon, and to these three political conquests correspond an equal number of linguistic varieties. If a given province now speaks Catalan rather than Castilian, the explanation is to be sought simply and solely in the fact that it was conquered by a king of Aragon and peopled by his Catalan subjects.

I CATALAN—This domain now embraces, on the main land, the Spanish provinces of Girona, Barcelona, Tarragona, and Lerida (the old principality of Catalonia), and of Castellon de la Plana, Valencia, and Alicante (the old kingdom of Valencia), and, in the Mediterranean, that of the Balearic Islands (the old kingdom of Majorca). Catalan, by its most characteristic features, belongs to the Romance of southern France and not to that of Spain, it is legitimate, therefore, to regard it as imported into Spain by those *Misraim* whom the Arab conquest had driven back beyond the mountains into Languedoc, and who in the 9th century regained the country of their origin, this conclusion is confirmed by the fact that the dialect is also that of two French provinces on the north of the Pyrenees—Roussillon and Cerdagne. From the 9th to the 12th century Catalan spread further and further within the limits of Catalonia, properly so called, in 1229 it was brought to Majorca by Jaime el Conquistador, and in 1238 the same sovereign carried it to Valencia also. Even Murcia was peopled by Catalans in 1266, but this province really is part of the Castilian conquest, and accordingly the Castilian element took the upper hand and absorbed the dialect of the earlier colonists. The river Segura, which falls into the Mediterranean in the neighbourhood of Orihuela, a little to the north of Murcia, is as nearly as possible the southern boundary of the Catalan domain, westward the boundary coincides pretty exactly with the political frontier, the provinces of New Castile and Aragon not being at all encroached on. Catalan, which by the reunion of Aragon and the countship of Barcelona in 1137 became the official language of the Aragonese monarchy,—although the kingdom of Aragon, consisting of the present provinces of Saragossa, Huesca, and Teruel, has always been Castilian in speech,—established a footing in Italy also, in all parts where the domination of the kings of Aragon extended, viz., in Sicily, Naples, Corsica, and Sardinia, but it has not maintained itself there in modern times except in a single district of the last-named island (Alghero), everywhere else in Italy, where it was not spoken except by the conquerors, nor written except in the royal chancery, it has disappeared without leaving a trace.

From the 13th century the name given to the vulgar tongue of eastern Spain has been *Catalanesch* (*Catalaniscus*) or *Catala* (*Catalanus*),—the idiom of the Catalans.¹ By *Catalanesch* or *Catala* was understood, essentially, the spoken language and the language of prose, while that of poetry, with a large admixture of Provençal forms, was early called *Lemosi*, *Limosi*, or language of Limousin,—Catalan grammarians, and particularly the most celebrated of them, Ramon Vidal de Besalú, having adopted *Lemosi* as the generic name of the language of the troubadours. These grammarians carefully distinguish the vulgar speech, or *pla Catala*, from the refined *trobar*

idiom, which originally is simply a more or less modified form of Provençal. Afterwards, and especially in those parts of the Catalan domain outside of Catalonia which did not care to acknowledge that they derived their language from that province, *Lemosi* received a more extensive signification, so as to mean the literary language in general, whether of verse or of prose. To this hour, particularly in Valencia and the Balearics, *Lemosi* is employed to designate on the one hand the old Catalan and on the other the very artificial and somewhat archaizing idiom which is current in the “*jocs florals*”, while the spoken dialect is called, according to the localities, *Valencià* (in Valencia), *Majorguè* and *Menorguè* (in Majorca and Minorca), or *Català* (in Catalonia), the form *Catalanesch* is obsolete.

The principal features which connect Catalan with the Romance of France and separate it from that of Spain are the following. (1) To take first its treatment of the final vowels,—Catalan, like French and Provençal, having only oxytones and paroxytones, does not tolerate more than one syllable after the tonic accent: thus *anima* gives *ama*, *càmera* gives *cambra*. All the proparoxytones of modern Catalan are of recent introduction and due to Castilian influence. Further, the only post-tonic Latin vowel preserved by the Catalan is, as in Gallo-Roman, *a mare* gives *mar*, *gratu(s)* gives *grat*, but *anima* gives *ama*, and, when the word terminates in a group of consonants requiring a supporting vowel, that vowel is represented by an *e*: *arb(o)rem*, Cat *arbre* (Prov and Fr *arbre*, but Cast *árbol*), *pop(u)l(us)*, Cat *poble* (Prov *poble*, Fr *peuple*, but Cast *pueblo*), sometimes, when it is inserted between the two consonants instead of being made to follow them, the supporting vowel is represented by an *o*: *escándol* (*scándalum*), *fríol* (*frivólus*), *círcol* (*circulus*). In some cases a post-tonic vowel other than *a* is preserved in Catalan, as, for example, when that vowel forms a diphthong with the tonic (*Deu*, *Deus*, *Ebrui*, *Hebrons*), or, again, it sometimes happens, when the tonic is followed by an *i* in hiatus, that the *i* persists (*dílvi*, *dilvíum*, *servici*, *servicium*, *láb*, *lábium*, *cerr*, *cereus*), but in many cases these ought to be regarded as learned forms, as is shown by the existence of parallel ones, such as *servey*, where the tonic *i* has been attracted by the tonic and forms a diphthong with it (*seivici*, *seiviu*, *seivey*). What has just been said as to the treatment of the final vowels in Catalan must be understood as applying only to pure Catalan, unaltered by the predominance of the Castilian, for the actual language is no longer faithful to the principle we have laid down, it allows the final *o* tonic in a number of substantives and adjectives, and in the verb it now conjugates *canto*, *temo*, *sento*,—a thing unknown in the ancient language. (2) As regards conjugation, only two points need be taken up here—(a) it employs the form known as the inchoative, that is to say, the lengthening of the radical of the present in verbs of the third conjugation by means of the syllable *ex* or *ix*, a proceeding common to Italian, Walachian, Provençal, and French, but altogether unknown in Hispanic Romance, (b) the formation of a great number of past participles in which the termination is added, as in Provençal, not to the radical of the verb, but to that of the perfect *tingut* formed from *tinch*, *pogut* from *poch*, *conegut* from *conech*, while Castilian says *tenido* (formerly also *tenido*), *podido*, *conocido*, that is to say, it forms those participles from the infinitive.

As for features common alike to Catalan and Hispanic (Castilian and Portuguese) Romance, on the other hand, and which are unknown to French Romance, there is only one which possesses any importance, the conservation, namely, of the Latin *u* with its original sound, while the same vowel has assumed in French and Provençal, from *a*

¹ The origin of the name *Catalanus* is unknown.

very early period,—earlier doubtless than the oldest existing monuments of those languages,—a labio palatal pronunciation (*ü*) It is not to be supposed that the separation of Catalan from the Gallo-Roman family should have occurred before the transformation had taken place, there is good reason to believe that Catalan possessed the *ü* at one time, but afterwards lost it in its contact with the Spanish dialects The question, however, is one for further examination

Catalan being a variety of the *langue d'oc*, it will be convenient to note the peculiarities of its phonetic and inflexion as compared with ordinary Provençal.

Tonic Vowels—With regard to *a*, which is pronounced alike in open and close syllables (*amar*, *amare*, *abre*, *arbor*), there is nothing to remark. The Latin *ē*, which is treated like *i*, gives *e*, sometimes close, sometimes open. On this point Catalan is more hesitating than Provençal, it does not distinguish so clearly the pronunciation of *e* according to its origin, while *ē* (*i*) is capable of yielding an open *e*, the *ē* is often pronounced close, and the poets have no difficulty in making words in *e* close and in *e* open rhyme together, which is not the case in Provençal. The Latin *ē* never yields *ie* in Catalan as it does in French and occasionally in Provençal, *sedet* becomes *seu* (where *u* represents the final *d*), *pedem* makes *pen*, and *ego eu*, in some words where the tonic *ē* is followed by a syllable in which an *i* occurs, it may become *i* (*vr*, *hōri*, *mig*, *mēdins*, *mūls*, *mōlins*), and the same holds good for *ē* in a similar situation (*arr*, *cōrins*, *cōreus*, *fira*, *fēria*), and for *e* in a close syllable before a nasal (*exempli*, *exemplum*, *mintré* for *menturé*, *gint* for *gent*) *I* tonic long and *i* short, when in hiatus with another vowel, produce *i* (*amicū*, *amicus*, *via*, *vīa*) *O* tonic long and *o* short are represented by *o* close and *o* open (*amor*, *amorem*, *poble*, *populus*) *O* short is never diphthongized into *uo* or *ue*, such a treatment is as foreign to Catalan as the diphthongization of *ē* into *ie*. Just as *e* before a syllable in which an *i* occurs is changed into *i*, so in the same circumstances *e* becomes *u* (*full*, *folium*, *vull*, *volio* for *voléo*) and also when the accented vowel precedes a group of consonants like *cl*, *pl*, and the like (*ull*, *oculus*, *escull*, *scopulus*) Latin *u* persists with the Latin pronunciation, and, as already said, does not take the Franco-Provençal pronunciation *ū* Latin *au* becomes *o* (*cosa*, *causa*, *or*, *aurum*), Old Catalan has kept the diphthong better, but possibly we should attribute the examples of *au* which are met with in texts of the 13th and 14th centuries to the literary influence of Provence. Latin *ua* tends to become *o* (*cor*, *quare*)

Atonic Vowels—As for the Latin post tonic vowels already spoken of, it remains to be noted that *a* is often represented in writing by *e*, especially before *s*, in old Catalan, the substantives, adjectives, and participles readily form their singular in *a* and their plural in *es* (*arma*, *armes* (anima, animas), *bona*, *bonas* (bona, bonas), *amada*, *amades* (amata, amatas)) This *e* is neither open nor close, but a surd *e* the pronunciation of which comes very near *a*. In the same way the supporting vowel, which is regularly an *e* in Catalan, is often written *a*, especially after *r* (*abra*, *arbor*, *astra*, *aetrum*, *para*, *patrem*), one may say that in the actual state of the language post tonic *e* and *a* become indistinguishable in a surd sound intermediate between the French *a* and mute *e*. Before the tonic the same change between *a* and *e* constantly takes place, one finds in manuscripts *enar*, *enor* for *anar*, *amor* (the same manner of writing extends even to the case of the tonic syllable, *ten* and *sent* from tantum and sanctum being far from rare), and, on the other hand, *entre*, *arrar*, for *entre*, *errar* *I* atonic is often represented by *e* even when it is long (*echi*, *vicinus*) *O* atonic close, which in genuine Catalan exists only before the tonic, has become *u*, at the present day *trubar*, *contradir* is the real pronunciation of the words spelt *trovar*, *contradir*, and in the final syllables, verbal or other, where under Castilian influence an *o* has come to be added to the normal Catalan form, this *o* has the value of a *u* (*trovo* (genuine Catalan, *trope*) is pronounced *trovu*, *bravo* (genuine Catalan, *bravi*) is pronounced *bravu*) *U* atonic keeps its ground

The only strong diphthongs of the spoken language are *ai*, *au* (rather rare), *ei*, *eu*, *iu*, *oi*, *ou*, *ui*. *Ai* produced by *a* + *i* or by *a* + a palatal consonant has for the greater part of the time become *au* in the modern language, *factum* has yielded *faut*, *fact*, and then *fet*, the last being the actual form, *arius* has given *er* alongside of *aire*, *ar*, which are learned or semi learned forms. Of the two weak diphthongs *eo* and *uo*, the latter, as has been seen, tends to become *o* close in the atonic syllable, and is pronounced *u* (*quaranta* has become *coranta*, then *curanta*). After the tonic *ua* often becomes *a* in the Catalan of the mainland (*ayga*, *aqua*, *llenga*, *lingua*), while in Majorca it becomes *o* (*aygo*, *llengo*)

Consonants—Final *i* readily disappears after *n* or *l* (*tan*, *tantum*, *aman*, *venin*, *partin*, for *amant*, *venint*, &c., *mol*, *multum*, *ocul*, *oculitum*), the *i* reappears in composition before a vowel (*fontem*, but *Font-alla*). On the other hand, a *i* without etymo-

logical origin is frequently added to words ending in *r* (*cart* for *car*, *quare*, *mart* for *mar*, *marc*, *amart*, *ohirt*, infinitive for *amar*, *ohir*), and even to some words terminating in a vowel (*genti*, *ingenium*, *premit*, *premium*), or the addition of the *i* has taken place by assimilation to past participles in *it*. The phenomenon occurs also in Provençal (see *Romania*, vii. 107, viii. 110) Median intervocal *d*, represented by *s* (*z*) in the first stage of the language, has disappeared *fidelis* gave *fescl*, then *fecl*, and finally *fel*, *videtis* became *veclis*, then *vecls*, *vcls*, and *veu*. Final *d* after a vowel has produced *u* (*peu*, *pedem*, *nu*, *nidum*, *mon*, *modum*), but, when the *d*, in consequence of the disappearance of the preceding vowel, rests upon a consonant, it remains and passes into the corresponding surd frigidus gives *fred* (pronounced *fret*) The group *dr*, when produced by the disappearance of the intermediate vowel, becomes *ur* (*creure*, *credere*, *ocire*, *occidere*, *veure*, *videre*, *seure*, *sedere*) Final *n*, if originally it stood between two vowels, falls away (*bo*, *bonum*, *vi*, *vinum*), but not when it answers to *nn* (thus *donum* makes *do*, but *domnum* *don*, *sonum* makes *so*, but *somnum* *son*) *Nd* is reduced to *n* (*demandar*, *comandar* for *demandar*, *comandar*) Assimilated *c* before *e*, *i* is treated like *d*, within a word it disappears after having been represented for a while by *s* (*lucere* gives *llusir*, *lluhir*, *recipere* gives *rezebre*, *rebre*, *rebre*), at the end of a word it is replaced by *u* (*reui*, *vicem*, *seu*, *fecit*) The group *c'r* gives *ur*, just like *d'r* (*gaure*, *jacere*, *naure*, *nocere*, *plaurer*, *placere*, but *facere*, *dicere*, *ducere*, *make far* (*fer*), *dur*, *dur*) Initial *l* has been preserved only in certain monosyllables (the article *lo*, *los*), everywhere else it has been replaced by *l* moullée (Prov *lh*), which in the present orthography is written *ll* as in Castilian, but formerly used to be represented by *ly* or *yl* (*lletra*, *littera*, *llengua*, *lingua*) *P* readily disappears after *m*, like *t* after *n* (*cam*, *campum*, *tempus*) *B* is replaced by the surd *p* at the end of a word (*trobare* in the infinitive, but *trop* in the present tense), so also in the interior of a word when it precedes a consonant (*supremur* *subicure*, *sopre*, *sub'to*) Median intervocalic *f* gives *v* (*Estêre*, *Stephanus*), it has disappeared from profundus, which yielded the form *preon*, then *pregon* (*g* being introduced to obviate the hiatus) *V*, wherever it has been preserved, has the same pronunciation as *b*, at the end of a word and between vowels it becomes vocalized into *u* (*suau*, *suavis*, *vivere*, *vivere*) *G* guttural, written *gu* before *e* and *i*, keeps its ground as a central and as a final letter, in the latter position it is generally written *ch* (*amicū*, *amicum*, *joch*, *jocum*) *G* guttural is replaced as a final letter by surd *c* (*longa*, but *long*, *trigar*, but *trich*) *Tj* after a consonant gives *ss* (*cassar*, *captiare*), between vowels, after having been represented by soft *s*, it has disappeared (*rationem* gave *razó*, *raysó*, then *rahó*), at the end of every word it behaves like *ts*, that is to say, changes into *ts* (*preu*, *pretium*), instead of *ts* the second person plural of the verb—at(*is*), et(*is*), it(*is*)—now has *au*, *cu*, *iu* after having had *ais*, *els*, *us* *Dj* gives *g* between vowels (*verger*, *viridiarum*), and *é* as a terminal (written either *ig* or *iz* *gong*, *gaudium*, *mig*, *mitz*, *medium*) *Sh* and *sc* before *e* and *i*, as well as *x* and *ps*, yield the sound *sh*, represented in Catalan by *x* (*angoza*, *angustia*, *conexer*, *cognoscere*, *dix*, *dixit*, *matez*, *metipse*) *J* almost everywhere has taken the sound of the French *j* (*judge*, &c.) *Lj* and *ll* give *l* moullée (*ll* in the present orthography *fill*, *filium*, *consell*, *conellum*, *null*, *nullum*) In the larger portion of the Catalan domain this *l* moullée has become *y*, almost everywhere *fiy* is pronounced for *fill*, *consey* for *consell* *Nj* and *nn* give *n* moullée (*nij* in both old and modern spelling *senyor*, *seniorem*, *any*, *annum*) Sometimes the *ny* becomes reduced to *y*, one occasionally meets in manuscripts with *seyor*, *ay*, for *senyor*, *any*, but this pronunciation has not become general, as has been the case with the *y* having its origin in *ll* Lingual *r* at the end of a word has a tendency to disappear when preceded by a vowel thus the infinitives *amare*, *temere*, *legere* are pronounced *amd*, *temé*, *legé* It is never preserved except when protected by the non etymological *t* already spoken of (*ilegit* or *ilegt*, but never *ilegitr*), the *r* reappears, nevertheless, whenever the infinitive is followed by a pronoun (*donarme*, *dirho*) *Rs* is reduced to *s* (*cor* for *cor*, *corpns*) *H* is merely an orthographic sign, it is used to indicate that two consecutive vowels do not form a diphthong (*echi*, *rahó*), and, added to *e*, it denotes the pronunciation of the guttural *c* at the end of a word (*amicū*)

Inflexion.—Catalan, unlike Old Provençal and Old French, has never had declensions. It is true that in certain texts (especially metrical texts) certain traces of case endings are to be met with, as for example *Deus* and *Deu*, *amors* and *amor*, *clars* and *clar*, *forts* and *fort*, *tuyt* and *tots*, *abduy* and *abdos*, *senyer* and *senyor*, *emperaire* and *emperador*, but, since these forms are used convertibly, the nominative form when the word is in the objective, and the accusative form when the word is the subject, we can only recognize in these cases a confused recollection of the Provençal rules which took no account of which the transcribers of manuscripts took no account. Catalan, then, makes no distinctions save in the gender and the number of its nouns. As regards the formation of the plural only two observations are necessary (1) Words which have their radical termination in *n* but which in the singular

drop that *n* resume it in the plural before *s* *homin-em* makes one in the singular and *omnes* in the plural, *asin* *nun* makes *as* and *asines*. (2) Words terminating in *e* surd or sonant and in *s* anciently formed their plural by adding to the singular the syllable *es* (*trax*, *traxes* *e* *præ*, *præ* *es*, *maler*, *maleres*), but subsequently from about the 14th century, the Castilian influence substituted *os*, so that one now hears *traxes* *præses* *maleres*. The words in *tr*, *s*, *e* have been assimilated to words in *s* (*s*), from *loach* we originally had the plural *laes* *les*, but now *loas* *is*, from *trist*, *tristes*, but now *tristes*. For those last in *e* there exists a plural formation which is more in accordance with the genius of the language, and consists in the suppression of the *e* before the *t* from *aguet*, for example, we have now side by side the two plurals *aguetes*, in the Castilian manner, and *aguets*. The article is *lo*, *les* (pronounced *lu*, *lue* in a portion of the domain), *fin* *lo*, *les* (*lav*). Some instances of *li* *o* *ur* in the ancient tongue, applying indifferently to the nominative and the objective case, *el* applying to the singular is *les* not wholly and now. On the north-western border of Catalonia, and in the island of Majorca, the article is not a derivative from *ille* but from *ipse* (sing. *ipse* *es* or *es*, *fin* *sa*, *pl* *ma* *es*, and *al* *o* *es* which appears to come from *ides*, *etc* for *e* *is* like *aguets* for *aguets* — *fin* *es* *es*). Compare the corresponding Sardinian forms *su*, *si*, *pl* *su*, *si*. On the pronouns it has only to be remarked that the modern language has borrowed from Castilian the *co* *op* *ur* forms *me* *vultres* and *me* *vultres* (pronounced also *me* *vultres* and *me* *vultres*), as also the forms *te*, *tu* *tu* (Castilian *te* *tu* for *tu* *tu* *tu* *tu*).

Composu Catalan, and especially modern Catalan, has greatly narrowed the domain of the 2d conjugation in *ere*, a large number of verbs of this conjugation have been treated as if they belonged to the "1st *ere*" debere makes *deire*, *videre*, *teure*, and alongside of *l'ier* which answers to *habere* there is a form *l'ar* which points to *habere*. A curious fact and one which has arisen since the 17th century, is the addition of a prerogative to those infinitives which are accented on the radical, in a portion of the Catalan domain one says *creuer* *creuer* *creuer*. Some verbs originally belonging to the conjugation in *ere* have passed over into that in *ere*. For example *tenere* gives *teure* alongside of *tenir*, remain *reure* and *romoure*. In the gerundive and in the present participle Catalan differs from Provencal in still distinguishing the conjugation in *er* from that in *er*, *re*—saying, for example, *cantant*. Even Provencal the past participle of a large number of verbs of the 2d and 3d conjugations is formed, not from the infinitive but from the perfect (*cantat*, *colgat*, *tingut* suggest the perfects *cantat*, *coltat*, *tingut*, and not the infinitives *poder*, *roter*, *tenre*). In the present indicative and subjunctive many verbs in *er* take the indicative form already described, by lengthening the radical in the three persons of the singular and in the third person of the plural by means of the syllable *es* (*es*) *cantar* has the present indicative *cantar*, *cantas*, *cantat*, *cantem*, *cantau*, *canten*, the present subjunctive *cant*, *cantis*, *cantat*, *cantem*, *cantau*, *canten*. The old perfect of the conjugation in *er* had *et* (*et*) in the 1st pers. sing. and *et* in the 3d, alongside of the *et*, which is proper to Catalan exclusively, we also find, in the first period of the language, *et* as in Provencal. Subsequently the perfect of the three conjugations has admitted forms in *r* (*amdre*, *ardre*, *ardre*, *ardre*, *ardre*, *ardre*), derived from the ancient pluperfect *a nari* *et*, which has held its ground down to the present day, with the meaning of a conditional in some verbs (one still hears *far*, *haquer*). But the simple perfect is no longer employed in the spoken language, which has substituted for it a periphrastic perfect, composed of the infinitive of the verb and the present of the auxiliary *anar*—*eu ja pendre*, for example, does not mean "I am going to take," but "I have taken." The earliest example of this periphrastic perfect carries us back to the 15th century. The most usual form of the only present in spoken Catalan is that in *er* for all the three conjugations (*am*, *er*, *er*, *em*, *eu*, *em*, *tem*, *er*, &c. *sent*, *er*, *er*), it appears to be an abbreviation from *er*, and in effect certain subjunctives, such as *cantat*, *tema*, *tingua*, *vingua* (for *cante*, *teua*, *tinga*, *vinga*), evidently formed upon *an* (subj. of *esser*), have been and still are used. The same *er* of the present subjunctive, whatever may be its origin, is still found in the imperfect *amde*, *erde*, *er*, *emde*, *er*.

Catalan Dialect of Algiers (Saraguna)—As compared with that of the mainland, the Catalan of Algiers, introduced into this portion of Saraguna by the Aragonese conquerors and colonists, does not present any very important differences, some of them, such as these are, are explicable by the influence of the indigenous dialects of *Syriani* and *Logudoro*. In phonetics one observes—(1) the change of *y* into *y* as an initial before *i* (*unx unys, lya, lens*), a change which does not take place in the Catalan of the mainland except in the interior, or at the end of the word, (2) the frequent change of *l* between vowels and of *l* after *e, g, f, p* or *h* into *r* (*laura, libula, candera, candela, sangrot, anquiltun, frama, flava*). In conjugation there are some notable peculiarities. The 1st pers sing does not take the *o* which continental Catalan has borrowed from Castilian (*cant, cant, do*), the imp ind of verbs of the 2d

and 3d conjugations has *era, ira* instead of *ia*, a form which also occurs in the conditional (*cauriera, drumirira*), the simple perfect, of which some types are still preserved in the actual language (*e q, aughé, aghé*), has likewise served for the formation not only of the past participle but also of the infinitive (*aqher, habere*, can only be explained by *ach*, 3d person of the perfect), the infinitives with *r* paradigm (*currer, seurer, plourer*) are not used (*curr, seure, plour* instead), in the conjugation of the present of the verb *cessar* or *cesser*, the 2d pers sing *ses* formed upon the persons of the plural, while continental Catalan says *els* (anciently *cel*), as also, in the plural, *scim, seu*, instead of *som, sou*, are to be noted, *tenir* has passed over to the conjugation in *re* (*tenula = tendre*), but it is at the same time true that in ordinary Catalan also we have *tuindrer* alongside of *tenir* the labutnal form, *dicere* gives not *dir* but *diure*, which is more regular.

IF CASTILIAN.—This name (derived from the kingdom of Castile, the most powerful element in the Spanish monarchy) is the most convenient designation to apply to the linguistic domain which comprises the whole of central Spain and the vast regions of America and Asia colonized from the 16th century onwards by the Spaniards. We might also indeed call it the *Spanish* domain, narrowing the essentially geographical meaning of the word *Español* (derived, like the other old form *Españon*, from *Hispania*), and using it in a purely political sense. But the first expression is to be preferred, all the more because it has been long in use, and even the inhabitants of the domain outside the two Castiles fully accept it and are indeed the first to call their idiom *Castellano*. It is agreed on all hands that Castilian is one of the two branches of the vulgar Latin of Spain, Portuguese Galician being the other, both idioms, now separated by very marked differences, can be traced back directly to one common source—the Hispanic Romance. One and the same vulgar tongue, diversely modified in the lapse of time, has produced Castilian and Portuguese as two varieties, while Catalan, the third language of the Peninsula, connects itself, as has already been pointed out, with the Gallo-Roman.

Within the Castilian domain, thus embracing all in Spain that is neither Portuguese nor Catalan, there exist linguistic varieties which it would perhaps be an exaggeration to call dialects, considering the meaning ordinarily attached to that word, but which are none the less worthy of attention. Generally speaking, from various circumstances, and especially that of the reconquest, by which the already formed idiom of the Christian conquerors and colonists was gradually conveyed from north to south, Castilian has maintained a uniformity of which the Romance languages afford no other example. We shall proceed in the first instance to examine the most salient features of the *normal Castilian*, spoken in the provinces more or less closely corresponding to the old limits of Old and New Castile, so as to be able afterwards to note the peculiarities of what, for want of a better expression, we must call the Castilian dialects.

In some respects Castilian is hardly further removed from classical Latin than is Italian, in others it has approximately reached the same stage as Provençal. As regards the tonic accent and the treatment of the vowels which come after it, Castilian may be said to be essentially a paroxytonic language, though it does not altogether refuse proparoxytonic accentuation and it would be a mistake to regard vocables like *lámpara*, *lágrima*, *rápido*, &c., as learned words. In this feature, and in its almost universal conservation of the final vowels *e*, *i*, *u* (*o*), Castilian comes very near Italian, while it separates from it and approaches the Gallo-Roman by its modification of the consonants.

Vowels—Normal Castilian faithfully preserves the vowels *e, i, o, ü*, the comparatively infrequent instances in which *e* and *o* are treated like *æ* and *u* must be attributed to the working of analogy. It diphthongizes *e* in *re*, *o* in *ne*, which may be regarded as a

[illegible]

It is with the Andalusian dialect that we can most readily associate the varieties of Castilian which are spoken in South America. Here some of the most characteristic features of the language of the extreme south of Spain are reproduced,—either because the Castilian of America has spontaneously passed through the same phonetic transformations or because the Andalusian element, very strongly represented in colonization, succeeded in transporting its local habits of speech to the New World.

Leonesc. — Proceeding on inadequate indications, the existence of a Leonesc dialect has been impudently admitted in some quarters, but the old kingdom of Leon cannot in any way be considered as constituting a linguistic domain with an individuality of its own. The fact that a poem of the 13th century (the *Alexandro*), and certain redactions of the oldest Spanish code, the *Fuero Juzgo*, have a Leonesc origin has been made too much of, and has led to a tendency to localize excessively certain features common to the whole western zone where the transition takes place from Castilian to Galician-Portuguese.

III. **Portuguese** — Portuguese Galician constitutes the second branch of the Latin of Spain. In it we must distinguish—(1) Portuguese (*Portuguez*, perhaps a contraction from the old *Portugale* = *Portugalensis*), the language of the kingdom of Portugal and its colonies in Africa, Asia, and America (Brazil), (2) Galician (*Gallego*), or the language of the old kingdom of Galicia (the modern provinces of Pontevedra, La Coruña, Orense, and Lugo) and of a portion of the old kingdom of Leon (the territory of Viero in the province of Leon). Portuguese, like Castilian, is a literary language, which for ages has served as the vehicle of the literature of the Portuguese nation constituted in the beginning of the 12th century. Galician, on the other hand, which began early in the Middle Ages a literary life,—for it was employed by Alfonso the Wise in his *cantigas* in honour of the Virgin,—decayed in proportion as the monarchy of Castile and Leon, to which Galicia had been annexed, gathered force and unity in its southward conquest. At the present day Gallego, which is simply Portuguese variously modified and with a development in some respects arrested, is far from having as a dialect the same importance as Catalan, not only because the Spaniards who speak it (1,600,000) number much less than the Catalans (3,500,000), but also because, its literary culture having been early abandoned in favour of Castilian, it inevitably fell into the vegetative condition of a provincial patois. Speaking generally, Portuguese is further removed than Castilian from Latin, its development has gone further, and its actual forms are more worn out than those of the sister language, and hence it has, not without reason, been compared to French, with which it has some very notable analogies. But, on the other hand, Portuguese has remained more exclusively Latin in its vocabulary, and, particularly in its conjugation, it has managed to preserve several features which gave it, as compared with Castilian, a highly melodic air. Old Portuguese, and more especially the poetic language of the 13th century, received from the language of the troubadours, in whose poetry the earlier Portuguese poets found much of their inspiration, certain words and certain turns of expression which have left upon it indelible traces.

Vowels.—Lat *æ*, with the accent, have not been diphthongized into *ae*, *no*, *ne* (*pudom*), *deæ* (*decom*), *bonæ* (*bonus*), *podeæ* (*potet*). On the other hand, Portuguese has a large number of strong diphthongs produced by the attraction of an *i* in hiatus or the resolution of an explosive into *i* *raiba* (*rabin*), *seira* (*foria*), *futo* (*foetum*), *seizu* (*saxum*), *oito* (*octo*). A quite peculiar feature of the language occurs in the "nasal vowels," which are formed by the Latin accented vowels followed by *n*, *ni*, or *nt*, *nd* *bã* (*bono*), *grã* (*gronum*), *bũ* (*honnim*). These nasal vowels enter into combination with a final atonic vowel *irmão* (*germonus*), also *amão* (*amont*), *seirão* (*sermonem*), where the *o* is a degenerated representative of the Latin final vowel. In Old Portuguese the nasal vowel or diphthong was not as now marked by the *til* (˘), but was expressed indifferently and without regard to the etymology by *m* or *n* *hem* (*honn*), *tan* (*tantum*), *disserom* (*dicornit*), *serrom* (*sermonem*). The Latin diphthong *au* is rendered in Portuguese by *ou* (*ouro*, *aureum*, *poço*, *panonim*), also pronounced *o*. With regard to the atonic vowels, there is a tendency to reduce *a* into a

vowel resembling the Fr *e* "muet," to pronounce *o* as *u*, and to drop *e* after a group of consonants (*dent* for *denté*).

Consonants.—Here the most remarkable feature, and that which most distinctly marks the wear and tear through which the language has passed, is the disappearance of the median consonants *l* and *n*. *corva* (corona), *lua* (luna), *pôr* formerly *poer* (ponere), *conego* (canonicus), *uir* (venire), *dur*, formerly *door* (dolorem), *paço* (palatium), *ruide* (salutem), *peço* (pelagus). Latin *b* passes regularly into *r* *cavallo* (caballus), *fava* (faba), *arvore* (arborum), but, on the other hand, Latin initial *c* readily tends to become *b* *beriga* (vesica), *bodo* (rotum). Latin initial *f* never becomes *h* *jazer* (facere), *filo* (filum). Latin *c* before *e* and *i* is represented either by the hard sibilant *s* or by the soft *z*. Latin *a* between vowels is dropped before *c* and *l* for *ler* (legere), *dedo* (digitum), the same is the case with *d*, of course, in similar circumstances *renir* (redimere), *rir* (ridere). Latin *j* has assumed the sound of the French *j*. The Latin combinations *cl*, *fl*, *pl* at the beginning of words are transformed in two ways in words of popular origin. Either the initial consonant is retained while the *l* is changed into *r* *craro* (clarum), *prazer* (placere), *fror* (floreum), or the group is changed in *ch* (= Fr *ch*, Catal. *x*) through the intermediate sounds *lj*, *ff*, *py* *chamar* (clamare), *chao* (pinus), *chamana* (flamma). Within the word the same group and other groups also in which the second consonant is an *l* produce *l* moullée (written *lh*, just as *n* moullée is written *nh*, as in Provençal) *orelha* (orella), *telho* (*reclius), and sometimes *ch* *facho* (fucium), *ancho* (nuplum). Lat. *ss* or *sc* before *e* and *i* gives *r* (Fr *ch*) *bauro* (basium), *fava* (fascia). The group *cl* is reduced to *l* *leito* (lectum), *peito* (pectus), *noite* (noctem), sometimes to *ul* *doulo* (doctus). Such words as *fruto*, *relo*, *diclo* are modern derivatives from the learned forms *fructo*, *relo*, *diclo*. Latin *es* becomes *is* *reis* (sex), or *ise*, *x* (= Fr *ich*, *ch*) *saizo* (saxum), *luvo* (luxum), or even *ss* *disse* (dixi).

Inflexion.—The Portuguese article, now reduced to the vocalic form *o*, *a*, *os*, *as*, was *lo* (exceptionally also *cl*, which still survives in the expression *El Rei*), *la*, *las*, *las* in the old language. Words ending in *l* in the singular lose the *l* in the plural (because it then becomes median, and so is dropped) *sol* (solem), but *soes* (soles), those having *uo* in the sing. form the plural either in *ões* or in *des* according to the etymology thus *cão* (canem) makes *ões*, but *ração* makes *rações*. As regards the pronoun, mention must be made of the non etymological forms of the personal *min* and of the feminine possessive *minha*, where the second *n* has been brought in by the initial nasal. Portuguese conjugation has more that is interesting in the personal suffixes the forms of the 2d pers. pl. in *ades*, *edes*, *ides* lost the *d* in the 15th century, and have now become *ais*, *eis*, *is* through the intermediate forms *aes*, *ees*, *eis*. The form in *des* has persisted only in those verbs where it was protected by the consonants *n* or *r* preceding it *pondes*, *tendes*, *rindes*, *amardes*, and also no doubt in some forms of the present of the imperative, where the theme has been reduced to an extraordinary degree by the disappearance of a consonant and the contraction of vowels *ides*, *eredes*, *ledes*, &c. Portuguese is the only Romance language which possesses a personal or conjugated infinitive *amar*, *amar es*, *amar*, *amar-mos*, *amar-des*, *amar em* *e g*, *antes de sair mos*, "before we go out." Again, Portuguese alone has preserved the pluperfect in its original meaning so that, for example, *amara* (amaveram) signifies not merely as elsewhere "I would love," but also "I had loved." The future perfect, retained as in Castilian, has lost its vowel of inflexion in the 1st and 3d pers. sing. and consequently becomes liable to be confounded with the infinitive (*amar*, *render*, *partir*) Portuguese, though less frequently than Castilian, employs *ter* (tenere) as an auxiliary, alongside of *aver*, and it also supplements the use of *essere* with *sedere*, which furnished the subj. *seja*, the imperative *se, sede*, the gerundive *sendo*, the participle *sido*, and some other tenses in the old language. Among the peculiarities of Portuguese conjugation may be mentioned—(1) the assimilation of the 3d pers. sing. to the 1st in strong perfects (*houre*, *pude*, *guiz*, &c.) while Castilian has *hubo* and *hubo*, (2) the imperfects *punha*, *tinha*, *tenha* (from *poner*, *ter*, and *haber*), which are accented on the radical in order to avoid the loss of the *n* (*ponha* would have made *poia*) and which substitute *u* and *i* for *o* and *e* in order to distinguish from the present subjunctive (*ponha*, *tenha*, *tenha*)

Galician.—Almost all the phonetic features which distinguish Portuguese from Castilian are possessed by Gallego also. Portuguese and Galician even now are practically one language, and still more was this the case formerly the identity of the two idioms would become still more obvious if the orthography employed by the Galicians were more strictly phonetic, and if certain transcriptions of sounds borrowed from the grammar of the official language (Castilian) did not veil the true pronunciation of the dialect. It is stated, for example, that Gallego does not possess nasal diphthongs, still it may be conceded once for all that such a word as *planns*, which in Galician is written sometimes *chau* and sometimes *chan*, cannot be very remote from the Portuguese nasal pronunciation *chao*. One of the most notable differences between normal Portuguese and Galician is the substitution of the surd spirant in place of the sonant spirant for the Lat. *j* before all vowels and *g* before *e* and *i* *zmes* (judicem), Port. *juz*, *zunto* (junctum), Port. *junto*, *zente* (gentem), Port. *gente*. In conjugation the peculiarities of Gallego are more marked, some find their explanation within the dialect itself, others seem to be due to Castilian influence. The 2d persons plural have still their old form *ades*, *edes*, *ides*, so that in this instance it would seem as if Gallego had been arrested in its progress while Portuguese had gone on progressing, but it is to be observed that with these full forms the grammarians admit contracted forms as well *as* (Port. *ais*), *es* (Port. *eis*), *is* (Port. *is*). The 1st pers. sing. of the perfect of conjugations in *er* and *ir* has come to be complicated by a nasal resonance similar to that which we find in the Portuguese *min*, we have *rendin*, *partin*, instead of *rendi*, *parti*, and by analogy this form in *in* has extended itself also to the perfect of the conjugation in *ar*, and *fain*, *gardin*, for *falei*, *garden* are found. The second persons of the same tense take the endings *chr*, *ches* in the singular and *chedes* in the plural *falache* or *falaches* (fabulasti), *falachedes* as well as *faldstedes* (fabulastis), *bateche* or *batiche*, pl. *batestes* or *batechedes*, &c. *Ti* (tibi) having given *che* in Galician, we see that *falasti* has become *falache* by a phonetic process. The 3d pers. sing. of strong perfect is not in *e* as in Portuguese (*houre*, *pode*), but in *o* (*houbo*, *pudo*, *soubo*, *coubo*, &c.), Castilian influence may be traceable here. If a contemporary grammarian, Saco Arce, is to be trusted, Gallego would form an absolute exception to the law of Spanish accentuation in the imperfect and pluperfect indicative *falabamos*, *falabades*, *bahamos*, *balades*, *pidamos*, *pidades*, and *falaríamos*, *falaríades*, *bateríamos*, *bateríades*, *pidaríamos*, *pidaríades*. The future perfect indicative and the imperfect subjunctive, on the other hand, would seem to be accented regularly *faldremos*, *faldremos*. The important question is worth further study in detail.

Bibliography.—On the general subject the only books to be mentioned are the *Grammatik der romanischen Sprachen* and the *Etymologisches Wörterbuch* of Diez. 1. CATALAN. On the old language see Manuel Miliá y Fontanals *De los Trovadores en España*, Barcelona, 1861, and several essays by the same author in the *Revue des Langues Romanes*, the *Jahrb. f. roman. u. engl. Literatur* vol. v, and the *Revista Histórica de Barcelona*. P. Meyer in *Romania*. A Mussafia in the introduction to *Die Catalanische metrische Version der sieben weisen Meister*, Vienna 1876 and Morel Fatio in *Romania*. For modern Catalan, see Ballot y Torres, *Grammatica y Apología de la Lengua Catalana*, Barcelona, 1814. A de Bofarull, *Estudios, Sistema Gramatical y Crestomatia de la Lengua Catalana*, Barcelona, 1864 and, before all, Manuel Miliá y Fontanals *Estudios de Lengua Catalana*, Barcelona, 1876. The dialectic varieties of Valencia and the Balearics have not yet been sufficiently investigated. On the Catalan of Alghero (Sardinia) there is a memoir by G. Morosi in the *Miscellanea di Filologia dedicata alla Memoria del Prof. Catt. e Casello*, Florence, 1880. 2. CASTILIAN. Since Diez's time no general work upon Castilian has been published, with the exception of a treatise on Spanish "doublets" by Mme. Carolina Michiels *Studien zur romanischen Wortbildung* Leipzig, 1876 and a *Spanische Sprachlehre* by Paul Fürster Berlin 1880, which leaves much to be desired. On the grammar of Old Castilian the remarkable articles of Cornu in *Romania* must be consulted. Hiltherto the dialects have received but little attention. For Asturian there is a *Colección de Poesías en Dialecto Asturiano* published at Oviedo in 1839 and some lexicographical notes. Appuntes *Lexicograficos sobre una Ramia del Dialecto Asturiano* by G. Laverde in the *Revista de Asturias* for 1879. Navarrese Aragonese has been worked at by Jerónimo Borao, *Diccionario de Locos Aragoneses*, 2d ed., Saragossa, 1885 and Andalusian has been very searchingly investigated by H. Schuchardt in *Zeitschr. f. rom. Philol.*, vol. v. On American-Spanish there is an excellent work by R. J. Cuervo *Apuntes Criticos sobre el Lenguaje Bogaiano* 4th ed. Charres, 1885. 3. PORTUGUESE. The researches of Diez have been followed up by F. Adolpho Coelho in two works, *Theoria da Conjugação em Latim e Portuguez*, Lisbon 1871 and *Questões da Lingua Portuguesa* 1st pt., Oporto 1874. M. Cornu and Coelho have contributed several very important articles in Portuguese to the *pages of Romania*. For Galician Saco Arce a *Grammatica Gallega* Lugo 1868 and A. Fernandez y Morales *Ensayos Poeticos en Dialecto Berciano* with introduction and glossary by Mariano Cabal y Soler, Leon 1861 ought to be consulted.

(A 31-F)

PART IV—LITERATURE

The name Spanish is now generally restricted to the literature of the Castilian tongue. In the present article it is taken in the wider sense as embracing the literature of the whole Iberian Peninsula, with the exceptions of Portuguese and Galician, the latter of which as regards language and literature belongs to the Portuguese domain. Spanish literature thus considered falls into two divisions—Castilian and Catalan.

I CASTILIAN LITERATURE.—Of the Castilian texts now extant none are of earlier date than the 12th century, and very probably none go farther back than 1150. That accepted as the oldest—the *Mystery of the Magian Kings*, as it is rather inappropriately designated—is a fragment of a short semi-liturgical play meant to be acted in the church of Toledo at the feast of Epiphany. Manifestly an imitation of the Latin *ludi* represented in France in the 12th

Heroic
poetry

century, the Spanish *piecco* cannot have been composed much before 1150

The great national hero Rodrigo Diaz do Bivar (died 1099), better known in history by the Arabic surname of the Cid (*q v*), was celebrated in the vulgar tongue less than a century after his death in two poems, neither of which, however, has come down to us in its entirety. The first *cantar*, usually entitled *Poema del Cid* since the first edition by Tomas Antonio Sanchez, relates in its first part the valiant deeds (*la gesta*) of the Cid subsequent to his quarrel with King Alfonso VI, in the second the capture of Valencia, the reconciliation of the hero with the king, and the marriage of his daughters with the "infantes" of Carrion,¹ and then in the third the treason of the infantes, the vengeance of the Cid, and the second marriage of his daughters with the infantes of Navarre and Aragon. The narrative of the last years of the Cid, which closes this third part, is very much entailed. Whilst in the *Poema* the Cid appears as the loyal vassal, faithful to his king and deploring the necessity of separating from him, the Cid of the second poem, *Cronica rimada del Cid*, is almost a rebel and at least a refractory vassal who dares treat his sovereign as an equal. The portion of the *Cronica* which has been preserved deals in the main with the youth (*mocedades*) of Rodrigo, it contains the primitive version of his quarrel with the Count Gomez do Gormaz, and the marriage of the slayer of the count with Ximena, his daughter, and also a series of fabulous episodes, such as the Cid's journey to France to fight with the twelve peers of Charlemagne, &c. If the *Poema* really belongs to the 12th century, some doubt attaches to the date of the *Cronica*, it would seem that the form under which this latter text has reached us is more recent than that of the *Poema*, but, on the other hand, several traditions collected by the author bear an incontestable stamp of antiquity. The versification of both poems is very barbarous, the metre very irregular. Normally this great epic measure ought to be divided into two hemistichs of seven or eight syllables each, but here the lines sometimes fall short of this number and sometimes exceed it. Instead of rhyme, assonance steadily prevails throughout, the strophes follow the model of the *laissez* of the French *chansons de geste*,—that is, they have a single assonance and vary greatly in extent.

The other heroes of Spanish history, such as the last Gothic king Roderick, Bernardo del Carpio, the infantes of Lara, have not given rise to long poems, at least we are acquainted with none of which they are the subject. Still some may have existed, and in fact the frequent allusions in the chronicle of Alfonso the Wise (13th century) to the narratives of the *juglares* suggest that Castilian heroic poetry was richer than the scarcity of the monuments still extant would lead us to believe. Fernau Gonzalez, first independent count of Castile (10th century), has alone been celebrated in a poem of the 13th century, composed in single-rhyme quatrains.

Poems
of 13th
century

With the heroic poetry which takes its themes from the national history and legends, there grew up in the 13th century a religious and didactic poetry, the most eminent representative of which is Gonzalo do Berceo (1198-1268). This poet, born at Berceo in the province of Logroño, composed several lives of Spanish saints (St Domingo de Silos, St Millau de la Cogulla, St Oria), and also devotional poems, such as the *Miracles* and the *Praises of the Virgin*, and some religious hymns. Berceo names his poems *prosa*, *dear*, *dictado*, indicating thereby that he intended them to be read and recited, not sung like the *cantares*. They are written in single-rhyme

quatrains and in verses of twelve to fourteen syllables, according as the ending of each hemistich is masculine or feminine. In the same kind of versification were composed, also in the 13th century, two long poems,—one on Alexander the Great, the other on Apollonius of Tyre,—after Latin and French sources. The author of the first of these poems contrasts his system of versification, which he calls *mester de clerecia*, with the *mester de joglaria*, the one of the heroic poetry, intended to be sung, and declares that this single rhyme quatrain (*cunso rimado por la quadera via*) consists of counted syllables. The composer of *Appolomo* calls this same versification *nueva maestra*. The single rhyme quatrain, introduced in imitation of the French poetry of the 12th century into Castilian literature, became from the time of Berceo and the *Alexandro* and *Appolomo* the regular form in Castilian narrative and didactic poetry, and prevailed down to the close of the 14th century.

To the 13th century seem also to belong a *Life of St Mary the Egyptian*, translated from the French, perhaps through a Provençal version, and an *Adoration of the Three Kings*, in verses of eight or nine syllables rhyming in pairs (*aa, bb, cc, &c*), as well as a fragment of a *Debate between Soul and Body*, in verses of six or seven syllables, evidently an imitation of one of those medieval Latin poems entitled *Rita Animi et Corporis*. Mention may here also be made of the *cantigas* ("songs") of Alfonso the Wise in honour of the Virgin, although, being in the Galician dialect, these properly belong to the history of Portuguese literature.

The 14th century saw the birth of the most original Poetry of 14th century
medieval Spanish poet Juan Ruiz (1300-1350), arch priest of Hita (near Guadalajara), has left us a poem of rather irregular composition, in which, while reproducing apologues translated from the Latin or French fabulists, and extracts from Ovid's *Art of Love*, or from a poem entitled *Pamphilus de Amore*, or, lastly, from *Jablanca* and *dis*, such as the *Bataille de Karesme et de Charnage*, the author frequently gives way to his own inspiration. Ruiz celebrates love and woman, his book is of *buen amor*, that is, he shows by his own experience and the example of the authors whom he follows how a man ought to set to work to be a successful lover. The character of the female goes between, named "Treta-Convencos," here plays an important part, it was suggested to Ruiz by the *Pamphilus*, but he has greatly strengthened the characteristics and thus prepared the way for the *Celestina* of the close of the 15th century. By way of precaution, the author represents himself as one who has survived his illusions, and maintains that carnal love (*loco amor*) must in the long run give place to divine love, but this stratum of devotion is a thin one and ought not to disguise the real character of the work. His form of versification is the single rhyme quatrain in the narrative portions, as to the "songs" (*cantigas*) which sometimes interrupt the narrative, and of which the most successful are a "song of scholars" and a "song of the blind," their rhythm is different and much more varied. The *Rimado de Palacio* of the grand chancellor of Castile, Pedro Lopez de Ayala (1332-1407), does not exclusively refer to court life, the author takes up all classes of laymen and churchmen, whose vices he depicts in jocular style. Amid the tirades of this long moral poem there occur occasionally some *cantares* or even *dearres* in strophes of eight lines of twelve syllables. akin to this *Rimado de Palacio* are the *Proverbios Morales* of the Jew Santob (Shemtob) of Carrion, dedicated to King Pedro the Cruel, who reigned from 1350 to 1369, as well as the *General Dance of Death* and a new version of the *Debate between Soul and Body*, both in eight-line strophes of *arte mayor* (verses of twelve syllables), and both imitations of

¹ Carrion de los Condes is a district in the province of Valencia.

French originals The 14th century also produced a long historical composition in verse, the *Rhymed Chronicle of Alfonso XI* (died 1350), by Rodrigo Yanez, important fragments of which have come down to us, the versification of this chronicle is similar to that of Santob's *Proverbs* (strophes of four octosyllabic verses rhyming *abab*)

Romances

The word romance not only signifies in Spain, as in other Romanic countries, the vulgar tongue, but also bears the special meaning of a short epic narrative poem (historic ballad) or, at a later date, a short lyric poem As regards the form, the "romance" (Spanish *el romance*, in contrast to French, &c., *la romance*) is a composition in long verses of fourteen syllables ending with one rhyme, or assonance, which have been generally, but wrongly, divided into two short lines, the first of which, naturally, is rhymeless This being the form of the romance verse, the *Crónica rimada del Cid*, and even the *Poema* (though in this case the influence of the French alexandrines is perceptible), might be considered as a series of romances tagged on one after the other, and in fact several of the old romances of the Cid, which form each an independent whole and have been printed as separate poems in the 16th century, are partly to be found in the *Crónica* Other romances, notably those dealing with the heroes of the Carolingian epic, so popular in Spain, or with the heroes which Spanish patriotism opposed at a certain period to the French paladins,—as, for example, Bernardo del Carpio, the rival and the conqueror of Roland in Castilian tradition,—seem to be portions severed from those *cantares de gesta* composed by *jugglers* of which Alfonso X makes mention It is only at the close of the 15th century, and especially during the 16th, that the romances, which had previously passed from mouth to mouth by song and recitation, began to be written down and afterwards to be printed, at first on broadsheets (*papeles sueltos*) and subsequently in collections (*romanceros*), either general, in which romances of very different date, character, and subject are mixed up, or restricted to a single historical or legendary episode or to a single personage (for example, the *Romancero del Cid*) In those collections the epic verse is always regarded as octosyllabic and printed as such, occasionally certain editions divide the romance into strophes of four verses (*cuartetos*)

Prose chronicles, 11th-16th centuries

King Alfonso X (died 1284), under whose patronage were published the memorable code entitled *Las Siete Partidas* and great scientific compilations, such as the *Libros de Astronomia* and the *Lapulario*, was also the founder of Spanish historiography in the vulgar tongue The *Crónica General*, composed under his direction, consists of two distinct parts the one treats of universal history from the creation of the world to the first centuries of the Christian era (*La General e Grant Historia*), the other exclusively of the national history (*La Crónica o Historia de España*) down to the death of Ferdinand III (1252), father of Alfonso The main sources of the *Crónica General* are two Spanish chroniclers of the 13th century,—Lucas of Tuy and Rodriguez of Toledo,—who wrote in Latin, but whose works were early translated into the vernacular In the *Historia de España* of Alfonso X which has collected many legends and which occasionally refers to the songs of the *jugglers* (for the purpose, however, of refuting them), the narrative relating to the Cid is partly based on an Arabic text This portion has frequently been printed by itself, under the title of *Crónica del Cid* Alfonso's example bore fruit In the 14th century, we find another *Crónica General de España* (or *Crónica de Castilla*) constructed on the model of the first and embracing the years 1030-1312 next, the *Grant Crónica de España* and the *Grant Crónica de los Conqueridores*, compiled by command of the grandmaster of the order of St John of Jerusalem, Juan Fernandez de Heredia, about

1390 Special chronicles of each king of Castile were soon written Our information is at fault in regard to the authorship of the chronicles of Alfonso X, Sancho IV, Ferdinand IV, and Alfonso XI, but the four following reigns—those of Pedro I, Henry II, John I, and Henry III—were dealt with by Pedro Lopez de Ayala, and here we can recognize the man of literary culture, who had acquired some knowledge of ancient history, for the form of the narrative becomes freer and more personal and the style rises with the thought Several authors had a hand in the chronicle of John II, but the final redaction was by Fernan Perez de Guzman The sad reign of Henry IV was related by Diego Enriquez del Castillo and Alfonso de Palencia, the glorious reign of the Catholic sovereigns Ferdinand and Isabella by Fernando del Pulgar and Andrés Bernaldes Along with those royal chronicles Bio- must be mentioned some biographies of important persons. ^{gr} Thus in the 15th century the chronicle of Pedro Niño, count of Buena (1379-1452), by Gutierre Diez de Gamez, that of Alvaro de Luna, constable of Castile (died 1453), also a very curious book of travels, the narrative of the embassy sent by Henry III of Castile to Timur in 1403, written by the head of the mission, Ruy Gonzalez de CLAVIJO (*qv*)

Other prose works of 13th and 14th centuries

The other productions of Castilian prose in the 13th and 14th centuries are for the most part didactic and sententious compositions, which, however, contain illustrations or tales of Eastern origin The Spanish translation of *Kahla and Dimna*, made direct from an Arabic text, dates from the middle of the 13th century, and the romance of the *Seven Sages (Sindibad)*, published under the title of *Engaños e Assayamientos de las Mugerres*, must be referred to almost the same period From the second half of the 13th century the collections of sentences, *dis*, apologues, and moral tales become very numerous first of all, versions of the *Secretum Secretorum*, attributed in the Middle Ages to Aristotle, one of which is entitled *Porridat de las Porridades*, next the *Proverbios Buenos*, the *Bocados de Oro* or *Libro de Bonum, Rey de Persia*, the *Libro de los Gatos*, which is derived from the *Narraciones* of Eudes of Cheriton But the most celebrated is the *Libro de los Castigos y Documentos* of King Sancho IV (died 1295), who also composed a *Luculario*, a kind of encyclopedia of theology, morals, and natural history It was during the first half of the 14th century that the nephew of Alfonso X, the infant Juan Manuel (1282-1349), wrote those various works which place him in the first rank of medieval Spanish prose writers The best known is the collection of tales, many of them borrowed from Oriental sources, entitled *El Conde Lucanor*, but besides this contribution to light literature he wrote graver and more specially instructive works, notably the *Libro de los Estados* or *Libro del Infante*, a kind of manual of education, domestic economy, and politics, the *Libro del Caballero e del Escudero*, a practical treatise on chivalry somewhat resembling a work of Raymond Lully on the same subject. Unfortunately Juan Manuel's poems, which he had collected in a *Libro de las Cantigas* or *de los Cantares*, have been lost The knowledge of antiquity, previously so poor and vague, made remarkable progress in the 14th century It was thought desirable to learn more about certain episodes of ancient history, such as the War of Troy, and therefore the poem on that subject by the Frenchman Benoit de Sainte More and the Latin narrative of Guido de Columna were both translated Pedro Lopez de Ayala translated or caused to be translated Pierre Bersuire's French version of Livy, Boetius, and various writings of Isidore of Seville and Beccaccio

While the Carolingian cycle is mainly represented in Books of Spain by romances, of which the oldest seem to be frag chivalry

ments of lost poems of the *juglares*, the British cycle (Lancelot, Tristram, Morin, &c.) is represented almost exclusively by works in prose (compare ROMANCE). Those narratives are known, it is true, only by 15th and 16th century editions in which they have been more or less modified to suit the taste of the time, but it is impossible not to recognize that books such as *El Baladro del Sabio Merlin* and *La Demanda del Sancto Grial* (1515) presuppose a considerable antecedent literature of which they are only the afterglow. The principal French romances of the Round Table were translated and imitated in Spain and in Portugal as early as the first half of the 14th century at least, of that there is no doubt. And, even if there was not on this point satisfactory testimony, the prodigious development in Spanish literature of the *caballerías* or "book of chivalry," incontrovertibly derived from fictions of British origin, is proof enough that the Spaniards have at an early date been familiarized with this romance from France. The first book which begins the series of strictly Spanish *caballerías* is the *Amadis de Gaula* (i.e., of Wales, not France). We know the *Amadis* only by the version made about 1480 in four books by Garcí Ordoñez de Montalvo (the oldest edition extant is dated 1508), but the work in its original form (three books), already widely distributed and celebrated by various Castilian poets from about 1350, must have been composed at the latest in the second third of the 14th century. A few rather vague hints and certain sentimental considerations lead one to seek for the unknown author of the first *Amadis* in Portugal, where the romances of the Round Table were even more highly appreciated than in Spain, and where they have exercised a deeper influence on the national literature. To Montalvo, however, falls the honour of having preserved the book by republishing it, he only made the mistake of diluting the original text too much and of adding a poor continuation, *Las Sergas de Esplandian*. Allied to Montalvo's *Amadis* with its *Esplandian* appendage are the *Don Florisando* and the *Lusitane de Grecia*, the *Amadis de Grecia*, the *Don Florisel de Niquea*, &c., which form what Cervantes called the "*Amadis sect*." Along with the *Amadis* range the *Palmerines*, the most celebrated of which are the *Palmerin de Oliva*, the *Primalcon*, and the *Palmerin de Inglaterra*. None of those *caballerías* inspired by the *Amadis* were printed or even written before the 16th century, and they bear in language and style the stamp of that period, but they cannot be separated from their mediæval model, the spirit of which they have preserved intact. Among the *caballerías* we may also class some narratives belonging to the Carolingian epic,—the *Historia del Emperador Carlomagno y de los Doce Pares*, a very popular version still reprinted of the French romance of *Fierabras*, the *Espejo de Caballeros*, into which has passed a large part of the *Orlando Innamorato* of Boiardo, the *Historia de la Reina Sibilla*, &c.

Poetry
of 15th
century

The first half of the 15th century, or, what comes almost to the same thing, the reign of John II of Castile (1407–1454), is as regards its literature characterized by three facts—(1) by the development of a court poetry, artificial and pretentious, (2) by the influence of Italian literature on Castilian prose and poetry, the imitation of Boccaccio and Dante, especially of the latter, which introduced into Spain a liking for allegory, and (3) by more assiduous intercourse with antiquity—a fuller understanding of the Latin writers who had been brought to the front by the Italian renaissance. After the example of the Provençals, whose literary doctrines had made their way into Castile through Portugal and Catalonia, poetry is now styled the *arte de trobar*. The *arte de trobar* is strictly "court" poetry, which consists in short pieces of rather

complicated versification,—love plaints, debates, questions, and repartees, *motets* with their *glosas*, burlesque and satirical songs,—a poetry wholly "occasional," and which when separated from its natural environment loses great part of its charm. In order to understand and appreciate these pieces they must be read in the collections made by the poets of the time, and the one must be brought to throw light on the other. The most celebrated *cancionero* of the 15th century is that compiled for the amusement of his sovereign by Alfonso de Brena (who has not designated himself a Jew, as has been supposed, the word *judino* attached to his name in the preface being nothing but *indino*), it is, so to say, the official collection of the poetic court of John II, although it also contains some pieces by poets of earlier date. After Brena's collection may be mentioned the *Cancionero de Suñiga*, which contains the Castilian poems of the *trobadores* who followed Alfonso V of Aragon to Naples. Those *cancioneros*, consisting of the productions of a society, a group, were succeeded by collections of a more general character in which versifiers of very different periods and localities are jumbled together, the pieces being classed simply according to their type. The earliest *Cancionero General* is that compiled by Juan Fernández de Constantina, which appears to have issued from the Valencia press in the very beginning of the 16th century, the second, much better known, was published for the first time at Valencia in 1511, its editor was called Fernando del Castillo. The other poetic school of the 15th century, which claims to be specially related to the Italians, had as its leaders Juan de Mena (1411–1456), author of the *Coronacion* and the *Labirinto* or *Las Tricentas* (a long poem so called because of the number of stanzas which, according to the scheme, were to compose it), and the marquis of Santillana, D. Íñigo López de Mendoza (1398–1458), who in his sonnets was the first to imitate the structure of the Italian *endecasillabo*. Along with those two, who may be designated *poetas*, in distinction from the *decadentes* and the *trobadores* of the *cancioneros*, must be ranked Lancelotti Imperial, a Genoese by descent, who also helped to acclimatize in Spain the forms of Italian poetry. The marquis of Santillana occupies a considerable place in the literature of the 15th century, not only by reason of his poems, but quite as much if not more through the support he afforded to all the writers of his time, and the impulse he gave to the study of antiquity and to the labours of translators who at his request turned Virgil, Ovid, Seneca, &c., into Castilian. He himself was not acquainted with Latin, but the generous efforts he made to stir up his fellow-countrymen to learn it have justly procured him the title of father of Spanish humanism. That he had an extensive knowledge of the national literature and of the literatures of France and Italy he has shown in the preface to his works, which is a sort of *ars poetica* as well as an historical exposition of the kinds of poetry cultivated in the Middle Ages by the Spaniards and the neighbouring nations.

With the exception of the chronicles and some *Prosa* *caballerías*, the prose of the 15th century contains nothing very striking. The translation of Virgil by Enrique de Villena (died 1434) is very clumsy and shows no advance on the versions of Latin authors made in the previous century, better worth reading is the *Trobar de Herodes*—a whimsical production but with some savour in its style. A curious and amusing book, full of details about Spanish manners, is the *Corbacho* of the archpriest of Talavera. Alonso Martínez de Toledo, chaplain to King John II, the *Corbacho* belongs to the numerous family of satires against women, and its title ("The Lash" or "Whip") borrowed from a work of Boccaccio, with which it has otherwise nothing akin, correctly indicates that he has not spared them.

Dra-
matic
litera-
ture

The ancient liturgical Spanish theatre is known to us only by fragments of the play of the *Magian Kings*, of which mention has already been made, but certain regulations of the code of the *Siete Partidas* (compiled between 1252 and 1257) prove that this theatre existed, and that at the great festivals, such as Christmas, Epiphany, and Easter, dramatic representations were given in church. These representations, originally a mere commentary on the liturgy, grew more complicated in course of time, they were gradually adulterated with buffoonery, which frequently brought down the censure of the clergy. Alfonso the Wise even thought it necessary formally to forbid the "clerks" playing *juegos de escarnios*, and permitted in the sanctuary only dramas destined to commemorate the principal episodes of the life of Christ. Of all the church festivals, the most popular in Spain was that of Corpus Christi, instituted by Urban IV in 1264. At an early date was introduced the custom of accompanying the celebration of this festival with dramatic representations intended to explain to the faithful the Eucharistic mystery. Those dramas, called *autos sacramentales*, acquired more and more importance, in the 17th century, with Calderon, they become grand allegorical pieces, regular theological dissertations in the form of dramas. To the *auto sacramental* corresponds the *auto al nacimiento*, or drama of the Nativity. The secular theatre in Spain as elsewhere a product of the religious theatre. Expelled from the church, the *juegos de escarnios* took possession of the public squares and there obtained a free development, they cease to be a mere travesty of dogma to become a separate type, a drama whose movement is no longer determined by the liturgy, and whose actors are borrowed from real life in Spanish society. This new theatre starts about the close of the 15th century with the little pastoral pieces of Juan del Encina (died 1534), which, after Virgil's example, he calls *eglogas*. Genuine shepherds, clumsy, rude, and long-haired (*melenudos*), are the interlocutors of those bucolics, into which are also sometimes introduced students, and even, by Lucas Fernandez, a contemporary and pupil of Encina's, gentlemen (*caballeros*) and soldiers. A book which, strictly speaking, does not belong to the theatre, the *Tragicomedia de Calisto y Melibea*, by Fernando de Rojas, much better known as *La Celestina*, and dating from about 1492, caused the new theatre, still so childish in the attempts of the school of Encina, to make a gigantic step onwards. The history of two lovers, who are brought together by a go-between (*Celestina*), and who after various vicissitudes ultimately commit suicide,—this astonishing novel taught the Spaniards the art of dialogue, and for the first time exhibited persons of all classes of society (particularly the lowest) speaking in harmony with their natural surroundings, thinking and acting in accordance with their condition of life. The progress caused by the *Celestina* may be estimated by means of the *Propaladia* of Bartolomé Torres Naharro (Naples, 1517), a collection of pieces represented at Rome in presence of Leo X and distributed by their author into two groups—*comedias a noticia*, those treating of things really known and seen, and *comedias a fantasia*, those bringing fictions on the stage, though it may be with the appearance of reality. The most interesting, if not the best composed, are the *comedia oldudera*, depicting to the life the Spanish man at arms of the time, and the *comedia tinelaria*, a picture of the manners of the menials of the pontifical court. Torres Naharro is the first Spaniard who borrowed from France the division of the play into "days" (*jornadas*), shortly after Naharro we find the comedy of manners in Lope de Rueda, goldbeater of Seville (died about 1566), whose dramatic work is composed of regular comedies constructed

on the model of Naharro and Italian authors of the beginning of the 16th century, and also of little pieces intended for performance in the intervals between the larger plays (*entremeses* and *pasos*), some of which, such as *El Convidado*, *El Rufian Cobarde*, *Las Aceitunas*, are storehouses of sprightliness and wit. Some of Naharro's and especially of Rueda's pieces have already the character of the comedy of intrigue, which is emphatically the type of the classic stage. But to reach Lope de Vega the Spanish stage had to be enlarged in relation to national history. A poet of Seville, Juan de la Cueva (born about 1550), first brought on the boards subjects such as the exploits of the Cid, Bernardo del Carpio, and others, which had previously been treated of only in the "romances." To a poet called Berrio, of whose work nothing has been preserved, are attributed the *comedias* of Moors and Christians, in which were represented famous episodes of the age-long struggle against the infidel. And it is at this period that Cervantes (1585) experimented in the dramatic line, in his *Tratos de Argel* he gives us a picture of galley-life, painful recollections of his long captivity in Algiers. There is no need to linger over certain attempts at tragedy of the ancient type by Geronimo Bermudez (born 1530), Cristóbal de Virnes (born about 1550), Luperco Leonardo Argensola (1562–1613), &c., the only successful specimen of which is the *Numancia* of Cervantes, these works in fact, cold and manneristic, mere exercises in style and versification, remained without influence on the development of the Spanish stage. The pre-classic period of this stage is, as regards dramatic form, one of indecision. Some write in prose, like Rueda, others, like Naharro, show a preference for the *redondillas* of popular poetry, and there are those again who, to elevate the style of the stage, versify in hendecasyllables. Hesitation is also evident as to the mode of dividing the drama. At first a division into five acts, after the manner of the ancients, is adopted, and this is still followed by Cervantes in his first pieces, then Juan de la Cueva reduced the five acts to four, and in this he is imitated by most of the poets to the close of the 16th century (Lope de Vega himself in his youth composed pieces in four acts). It was only at this time that the custom which is still maintained of dividing all dramatic works into three acts or days was introduced,—exception of course being made of short pieces like the *loa* (prologue), the *entremes*, the *paso*, the *baile* (different kinds of *entr'acte*).

The golden age of Spanish literature, as it is called, belongs to the 16th and the 17th centuries, extending approximately from 1550 to 1650. Previous to the reign of the Catholic sovereigns there exists, strictly speaking, only a Castilian literature, not very self-reliant and largely influenced by imitation first of France and then of Italy, the union of the two crowns of Aragon and Castile, and afterwards the advent of the house of Austria and the king of Spain's election as emperor, proved the creation at once of the political unity of Spain and of Spanish literature. After the death of Philip IV (1665) this fair-shining light went out, the nation, exhausted by distant expeditions, the colonization of America, Continental wars, and bad administration, produced nothing, its literary genius sank in the general decline, and Spain is destined ere long to be subjected again to the influence of France, to which she had submitted during all the first period of the Middle Ages. In the 16th and 17th centuries the literature is eminently national. Of course all is not equally original, and in certain kinds of literature the Spaniards continue to seek models abroad.

Lyric poetry, especially that of the highest order, is Lyne always inspired by the Italian masters. An irresistible poetry

turies.

tendency leads the Spanish poets to rhyme in hendecasyllables—as the marquis of Santillana had formerly done, though his attempts had fallen into oblivion—and to group their verses in tercets, octaves, sonnets, and *canciones* (*canzoni*). Garcilaso de la Vega (1503–1536), Juan Boscan (1493–c. 1550), and Diego de Mendoza (1503–1575) are the recognized chiefs of the school *à l'italico modo*, and to them belongs the honour of having successfully transplanted to Spain those different forms of verse, and of having enriched and improved the poetic language of their country. The few uncouthnesses of which Mendoza and Boscan more especially are guilty (such as certain faults of rhythmic accentuation) were corrected by their disciples Gutierre de Cetina, Gregorio Silvestre, Hernando de Acuña, by the poets of the so called school of Seville, headed by Fernando de Herrera (died 1597), and also by those of the rival school of Salamanca, rendered famous mainly by the inspired poetry of Fr. Luis de León (1528–1591). Against those innovators the poets faithful to the old Castilian manner, the rhymers of *redondillas* and romances, hold their own, under the direction of Cristóbal de Castillejo (1556) they carry on a fierce war of the pen against the “Petrarchists.” But by the last third of the 16th century the triumph of the new Italian school is assured, and no one any longer thinks of reproaching it for its foreign flavour. Only a sort of schism is effected from that period between the higher poetry and the other varieties: the former employs only the hendecasyllabic and the heptasyllabic (*quebrado*), while the popular poets, or those who affect a more familiar tone, preserve the national metres. Almost all the poets, however, of the 16th and 17th centuries have tried their powers in both kinds of versification, using them in turn according to the nature of their subjects. Thus Lope de Vega, first of all, who wrote *La Jerusalem Conquistada* (1609), *La Dragontea* (1602), *La Hermosura de Angélica* (1602), in Italian verses and in octaves, composed his long narrative poem on Isidore, the husbandman patron of Madrid (1699), in quintils of octosyllabic verse, not to mention a great number of “romances.” As regards this last form, previously disdained or almost so by artistic poets, Lope de Vega gave it a prestige that brought it into favour with the literates of the court. A host of poets were pleased to recast the old “romances” or to compose new ones. The 17th century, it may be said, is characterized by a regular surfeit of lyric poetry, to which the establishment of various literary academies in the Italian style contributed not a little. Of this enormous mass of verses of all sorts and sizes very little still keeps afloat: the names of three-fourths of the versifiers must be forgotten, and in addition to those already cited it will be sufficient to mention Luis de Góngora (1561–1626) and Francisco de Quevedo Villegas (1580–1645). Góngora is especially famous as the founder of the “cultist” school, as the introducer into Castilian poetry of a flowery, bombastic, and periphrastic style, characterized by sonorous vocables and artificial arrangements of phrase. The Spaniards have given the name of *culto* to this pompous and manneristic style, with its system of inversions based on Latin syntax. The *Soledades* of Góngora are the monument *par excellence* of Spanish mannerism, which made numerous victims and inflicted on the poetry of the Peninsula irreparable injury. But Góngora, a poet of really great powers, had started better, and as often as he cares to forget about being sonorous and affected, and is contented to rhyme romances, he finds true poetic accents, ingenious ideas, and felicitous expressions. Quevedo, much greater, moreover, in his prose works than in his verse, displays real power only in satire, epigram, and parody. There are in some of his serious pieces the stuff of a Juvenal, and his satiric and

burlesque romances, of which several are even written in slang (*germanica*), are in their way little masterpieces. Another commonplace of Spanish poetry at this period was epic poetry after the style of Tasso's *Gerusalemme*. None of those interminable and prosaic compositions in *octavas reales* come near their model, none of them could even be compared in style, elevation of thought, and beauty of imagery to the *Lusiadas*. They are in reality only rhymed chronicles, and consequently, when the author happens to have taken part in the events he narrates, they have a genuine historical interest. Such is the case with the *Araucana* of Alonso de Ercilla (1533–1594), of which it may be said that it was written less with a pen than with a pike. In burlesque poetry the Spaniards have been rather more successful. *La Gatomaquina* of Lope de Vega and *La Mosquera* of Villaviciosa (died 1658) are somewhat agreeable pieces of fun.

The departments of imaginative literature in which the Ro-
genius of the new Spanish nation revealed itself with most ^{marked} vigour and originality are the *novela* and the drama. By *novela* must be understood the novel of manners, called *picaresca* (from *pícaro*, a rogue or “picaroon”) because of the social status of the heroes of those fictions, and this kind of novel is quite an invention of the Spaniards. Their pastoral romance, on the other hand—the best known examples of which are the *Diana Enamorada* of Jorge de Montemayor (died 1561), continued by Alonso Perez and Gaspar Gil Polo, the *Galatea* of Cervantes, and the *Arcadia* of Lope de Vega, as well as their novel of adventure, started by Cervantes in his *Novelas Ejemplares* (1613), and cultivated after him by a host of writers—is directly derived from Italy. The *Arcadia* of Sannazaro is the source of the *Diana* and of all its imitations, just as the Italian *novellieri* alone are the masters of the Spanish *novelistas* of the 17th century. The picaresque novel starts in the middle of the 16th century with the *Vida de Lazarillo de Tormes, sus Fortunas y Adversidades* (1554), the work of a very bold intellect whose personality unfortunately remains unknown, there being no satisfactory reason for assigning this little book, which is as remarkable for the vigour of its satire as for the sobriety and firmness of its style, to Diego Hurtado de Mendoza. A supplement to the adventures of Lazarillo appeared at Antwerp in 1555, it is probably, however, not the production of the author of the original romance. The impetus was given, and the success of *Lazarillo* was so great that imitators soon appeared. In 1599 Mateo Aleman published, under the title of *Atalaya de la Vida Humana*, the first part of the adventures of another picaroon, Guzman de Alfarache, and, as he was in no hurry to finish this narrative, another writer, jealous of his success, took possession of it and issued in 1603, under the pseudonym of Mateo Luván, a continuation of the first Guzman Aleman, not to be thwarted, resumed his pen, and published the second part of his romance in 1605. Quite unlike that of the *Lazarillo*, the style of Mateo Aleman of Seville is eloquent, full, with long and learned periods, sometimes diffuse. Nothing could be more extravagant and more obscure than the history of Justina the beggar woman (*La Pícarra Justina*) by Francisco Lopez de Ubeda (1605), an assumed name which concealed the person of the Dominican Andrés Perez de Leon. The other picaresque romances are—*Alonso Mozo de muchos Amos*, by Geronimo de Alcalá (two parts, 1624 and 1626), the *Historia y Vida del Gran Tacaño Pablo de Segovia* (1626), in which Quevedo has made his most brilliant display of style and wit, the *Garduña de Sevilla* (1634) of Alonso de Castillo Solorzano, *La Vida y Hechos de Estebanillo González* (1646), described as *compuesto por el mismo*, but an Estéban González is unknown in the literary history of the 17th century.

By degrees the picaresque romance was combined with the novel of Italian origin and gave rise to a new type,—half novel of manners, half romance of adventure,—of which the characteristic example appears to be the *Relacion de la Vida y Aventuras del Escudero Marcos de Obregon* (1618), by Vicente Espinel, one of the most genial and best written works of the 17th century. To the same class belong almost all the novels of Alonso Gerónimo de Salas Barbadillo, such as *La Ingeniosa Helena*, *Don Diego de Noche*, *El Caballero puntual*, &c., Luiz Velez de Guevara's *Diablo Cojuelo* (1641), the model of Lesage's *Diabolo Botteur*, and Francisco Santos's highly popular pictures of life in Madrid, *Dia y Noche de Madrid* (1663), *Periquillo*, *el de las Gallineras*, &c. On the contrary, the novels of Tirso de Molina (*Los Cigarrales de Toledo*, 1624), Perez de Montalban (*Para Todos*, 1632), Maria de Zayas (*Novelas*, 1637), are more in the manner of the *Novelas Ejemplares* of Cervantes, and consequently of the Italian type. Among the so called historical romances one only deserves to be mentioned,—the *Guerras Civiles de Granada* by Gines Perez de Hita, which deals with the last years of the kingdom of Granada and the insurrection of the Moors of the Alpujarras in the time of Philip II. *Don Quixote*, the masterpiece of Miguel Cervantes de Saavedra (1547–1616), is too great a work to be treated along with others, and, besides, it does not fall strictly within the limits of any of the classes just mentioned. If it has to be defined, it may be described as the social romance of 16th and 17th century Spain. Cervantes undoubtedly owed much to his predecessors, notably to the picaresque romancers, but he considerably enlarged the scope of the type, and, what had as yet been done by no one, supported the framework of the story by a lofty moral idea. His main purpose was, as we are beginning to realize, not to turn into ridicule the books of chivalry, which were already out of fashion by his time, but to show by an example pushed to absurdity the danger of *hidalgism*, of all those deplorable prejudices of pure blood and noble race with which three-fourths of the nation were imbued, and which, by the scorn of all useful labour which they involved, were destined to bring Spain to ruin. The lesson is all the more effective as his *hidalgo*, although ridiculous, was not put beyond the pale of the reader's sympathy, and the author condemns only the exaggeration of the chivalrous spirit, and not true courage and devotion when these virtues have a serious object. The same thing happened to *Don Quixote* which had happened to *Guzman de Alfarache*. After the publication of the first part (1605), Cervantes allowed his pen to lie too long idle, and so it occurred to some one to anticipate him in the glory of completing the story of the heroic deeds of the knight of La Mancha. In 1614 a second part of the adventures of Don Quixote made its appearance—the work of a certain Avellaneda, a pseudonym under which people have sought to recognize the inquisitor Luis de Alaga. Cervantes was thus roused from inactivity, and the following year gave to the world the true second part, which soon effaced the bad impression produced by Avellaneda's heavy and exaggerated imitation.

Drama
of 17th
century

The stage in the 17th century in some measure took the place of the romances of the previous age, it is, as it were, the medium of all the memories, all the passions, and all the aspirations of the Spanish people. Its style, being that of the popular poetry, made it accessible to the most illiterate classes, and gave it an immense range of subject. From the books of the Bible, the acts of the martyrs, national traditions, the chronicles of Castile and Aragon, and foreign histories and novels, down to the daily incidents of contemporary Spanish life, the escapades and nightly brawls of students, the gallantries of the Calle

Mayor and the Prado of Madrid, balcony escalades, sword thrusts and dagger strokes, duels and murders, fathers befooled, jealous ladies, pilfering and cowardly valets, inquisitive and sprightly waiting maids, sly and tricky peasants, fresh country girls,—all are turned to dramatic account. The enormous mass of plays with which the literature of this period is inundated may be divided into two great classes—secular and a religious, the latter again subdivided into (1) the liturgical play, *i.e.*, the *auto* either *sacramental* or *al nacimiento*, and (2) the *comedia divina* and the *comedia de santos*, which have no liturgical element and differ from a secular play only in the fact that the subject is religious, and frequently, as one of the names indicates, derived from the history of a saint. In the secular drama, classification might be carried almost to any extent if the nature of the subject be taken as the criterion. It will be sufficient to distinguish the *comedia* (*i.e.*, any tragic or comic piece in three acts) according to the social types brought on the stage, the equipment of the actors, and the artifices resorted to in the representation. We have (1) the *comedia de capa y espada*, which represents any everyday incident, the actors belonging to the middle class, simple *caballeros*, and consequently wearing the garb of ordinary town life, of which the chief items were the cloak and the sword, and (2) the *comedia de teatro* or *de ruido*, or again *de tramoya* or *de apariencias* (*i.e.*, the theatrical, spectacular, or scenic play), which prefers kings and princes for its *dramatis personæ* and makes a great display of mechanical devices and decorations. Besides the *comedia*, the classic stage has also a series of little pieces subsidiary to the play proper: the *loa* or prologue, the *entremes*, a kind of interlude which afterwards developed into the *saynete*, the *baile*, or ballet accompanied with singing, and the *zarzuela*, a sort of operetta thus named after the royal residence of La Zarzuela, where the kings of Spain had a theatre. As to the dramatic poets of the golden age, even more numerous than the lyric poets and the romancers, it is rather difficult to group them. All are more or less pupils or imitators of the great chief of the new school, Lope Felix de Vega Carpio (1562–1635), everything has ultimately to be brought back to him whom the Spaniards call the "monster of Nature." Among Lope's contemporaries, only a few poets of Valencia (Gaspar de Aguiar, Francisco Tarrega, Guillem de Castro (1569–1631), the author of the *Mocedades del Cid* (from which Corneille derived his inspiration), formed a small school, as it were, less subject to the master than that of Madrid, which was bound to merit the applause of the public by copying as exactly as possible the manner of the great initiator. Lope left his mark on all varieties of the *comedia*, but did not attain to equal excellence in all. He was especially successful in the comedy of intrigue (*enredo*), of the *capa y espada* class, and in dramas whose subjects are derived from national history. His great and most incontestable merit is to have given the Spanish stage a range and scope of which it had not been previously thought capable, and of having taught his contemporaries to find dramatic situations and to carry on a plot. It is true he wrote nothing perfect: his prodigious productiveness and facility allowed him no time to mature anything, he wrote negligently, and, besides, he considered the stage an inferior department, good for the *vulgo*, and consequently did not judge it worthy of the same regard as lyric or narrative poetry borrowed from the Italians. Lope's first pupils exaggerated some of his defects, but, at the same time, each, according to his own taste, widened the scope of the *comedia*. Antonio Mira de Amescua and Luis Velez de Guevara (died 1644) were successful especially in tragic histories and *comedias divinas*. Fr. Gabriel Tellez (1570–

1648), better known under the pseudonym of Tirso de Molina, one of the most flexible, ingenious, and inventive of the dramatists, displayed no less talent in the comedy of contemporary manners than in historical drama. *El Burlador de Sevilla (Don Juan)*, the most celebrated of his plays since the Italians and the French have taken possession of the subject, is reckoned his masterpiece, but he showed himself a much greater poet in *El Vergonzoso en Palacio*, *Don Gil de las Calzas Verdes*, *Marta la Padosa*. Finally Juan Ruiz de Alarcón (died 1639), the most serious and most observant of Spanish dramatic poets, successfully achieved the comedy of character in *La Verdad Sospechosa*, closely followed by Conneillo in his *Mentum*. The remaining play writers hardly did anything but increase the number of the comedias, they added nothing to the real elements of the drama. The second epoch of the classical drama is represented mainly by Pedro Calderón de la Barca (1600–1681), the Spanish dramatist who has obtained most celebrity abroad, where his pieces have been studied and admired (perhaps extravagantly) by certain critics who have not feared to rank him with Shakespeare. It is Calderón who first made honour, or more correctly the point of honour, an essential motive in the conduct of his personages (e.g., *El Médico de su Honra*), it is he also who made the *comedia de capa y espada* uniform even to monotony, and gave the comic "part" of the *gracioso* (confidential valet of the caballero) a fixity which it never previously possessed. There is depth and poetry in Calderón, but vagueness also and much bad taste. His most philosophic drama, *La Vida es Sueño*, is a bold and sublime idea, but indistinct and feebly worked out, that his *autos sacramentales* give evidence of extensive theological knowledge is all that can be said in their favour. Calderón was imitated, as Lope had been, by exaggerating his manner and perverting his excellencies. Two poets only of the second half of the 17th century deserve to be cited along with him—Francisco de Rojas, author of the fine historic play *El Rey abajo ninguno*, and Agustín Morote (1618–1662), author of some pleasant comedies. Among those who worked in secondary forms mention must be made of Luis Quiñones de Benavente, a skilful writer of *entremeses*, and in fact the greatest master of the form.

History A new manner of writing appears with the revival of learning the purely objective style of the old chroniclers, with their tagging on of one fact after another, without showing the logical connexion or expressing any opinion on men or things, begins to be thought puerile. An attempt is now made to treat the history of Spain in the manner of Livy, Sallust, Tacitus, whose methods of narration were directly adopted. The 16th century, however, still presents certain chroniclers of the mediæval type, with more erudition, precision, and a beginning of the critical element. *La Crónica General de España* by Ambrosio de Morales, the *Compendio Historial* of Estéban de Garibay, the *Historia General de las Indias Occidentales* by Antonio de Herrera, are, as far as the style is concerned, continuations of the last chronicles of Castile. Gerónimo de Zurita (1512–1580) is emphatically a scholar, no one in the 16th century knew as he did how to turn to account documents and records for the purpose of completing and correcting the narratives of the ancient chronicles, his *Anales de la Corona de Aragón* is a book of great value, though written in a painful style. With Juan de Mariana (1536–1623) history ceases to be a mere compilation of facts or a work of pure erudition, in order to become a work of art and of thought. The *Historia de España* by the celebrated Jesuit, at first written in Latin in the interest especially of foreigners, was afterwards rendered by its author into excellent Castilian, as a general survey of

its history, well planned, well written, and well thought out, Spain possesses nothing that can be compared with it, it is eminently a national work, steeped throughout in the prejudices of the race. Various works of less extent,—accounts of more or less important episodes in the history of Spain,—may take their place beside Mariana's great monument for example, the *Guerra de Granada* by Diego Hurtado de Mendoza (a history of the revolt of the Moors of the Alpujarras under Philip II), written about 1572, immediately after the events, but not published till about thirty years later, after the author's death, the narrative of the expedition of the Catalans in the Morca in the 14th century by Francisco de Moncada (died 1635), that of the revolt of the same Catalans under the reign of Philip IV by Francisco Manuel de Melo (died 1666), a Portuguese by birth and that of the conquest of Mexico by Antonio de Solís. Each of these writers has been more or less inspired by some Latin author, one preferring Livy, another Sallust, &c. These imitations, it must be admitted, have something artificial and stilted, which in the long run proves as fatiguing as the unskilfulness and heaviness of the chroniclers of the Middle Ages. On the other hand, the historians of the wars of Flanders, such as Carlos Coloma, Bernardino de Mendoza, Alonso Vázquez, Francisco Verdugo, are less refined, and for that very reason are more vivid and more thoroughly interest us in that struggle of the two races, so foreign to each other and of such different genius. As for the accounts of the transatlantic discoveries and conquests, they are of two kinds,—either (1) memoirs of the actors or witnesses of those great dramas, as, e.g., the *Historia Verdadera de la Conquista de la Nueva España* by Bernal Díaz del Castillo, one of the companions of Cortés, and the *Historia de las Indias* by P. Bartolomé de las Casas, the apostle of the Indians, or (2) works by professional writers, such as Francisco López de Gomara,—official his toriographers who wrote in Spain on information sent to them from the newly-discovered lands.

Letter writers, a rather numerous body in Spanish literature, are nearly related to the historians, in fact, letters written to be read by others than the persons addressed, or in any case revised afterwards, are only another method, a little more familiar, of writing history. Fernando del Pulgar appended to his *Grandes Varones* a series of letters on the affairs of his time, and at the commencement of the 16th century Antonio de Guevara (died 1545) collected, under the title of *Epistolae Familiaris*, his correspondence with his contemporaries, which throws a great light on the early part of the reign of Charles V, although it must be used with caution because of the numerous *refacimientos* it has undergone. A celebrated victim of Philip II, Antonio Perer (died 1611), revenged himself on his master by relating in innumerable letters, addressed during his exile to his friends and protectors, all the incidents of his disgrace, and by selling to the ministers of France and England the secrets of the Spanish policy in which he had a hand, some of these letters are little masterpieces of sprightliness and gallantry.

Philosophy is rather poorly represented in the 16th and 17th centuries in the literature of the vernacular. Theosophy greater number of the Spanish thinkers of this epoch, whatever the school to which they belonged,—scholastic, Platonic, Aristotelian, or independent,—wrote in Latin. Ascetic and mystical authors alone made use of the vulgar tongue for the readier diffusion of their doctrine among the illiterate, from whose ranks a good number of their disciples were recruited. Fr. Luis de Granada (died 1588) the great preacher, Juan de la Cruz (1542–1591), Fr. Luis de León (1528–1598), Teresa de Jesús (1515–

1582), and Malon de Chaide are the brighter lights of this class of writers. Some of their books, like the *Guia de Pecadores* of Fr Luis de Granada, the *Confessions* of St Teresa, Malon de Chaide's *Conversion of the Magdalen*, have obtained a brilliant and lasting success beyond the limits of the Peninsula, and have not been without some influence on the development of mysticism in France. The Spanish mystics are not only remarkable for the depth or subtlety of their thoughts and the intensity of the divine love with which they are inspired, many of them are masters of style, some, like Juan de la Cruz, have composed verses which rank with the most delicate in the language. A notable fact is that those men who

Moralists, are regarded as illuminati profess the most practical ideas in the matter of morality. Nothing is more sensible, nothing less ecstatic, than the manual of domestic economy by Fr Luis de Leon—*La Perfecta Casada*. Lay moralists are very numerous in the 16th and 17th centuries. Some write long and heavy treatises on the art of governing, the education of princes, the duties of subjects, &c. Pedro Fernandez de Navarrete's *Conservacion de Monarquias*, Diego de Saavedra Faxardo's *Idea de un Principe Cristiano*, Quevedo's *La Politica de Dios y Gobierno de Cristo*, give a correct idea of the ability which the Spaniards have displayed in this kind of didactic and preceptorial literature,—ability of no high order, for the Spaniard, when he means to teach and work out a doctrine, loses himself in distinctions and rapidly becomes diffuse, pedantic, and obscure. But there is a kind of morality in which he indubitably excels, namely, in social satire, which, under all its forms,—dialogue and dream in the style of Lucian, epistle after the manner of Juvenal, or pamphlet,—has produced several masterpieces and a host of ingenious, caustic, and amusing compositions. Juan de Valdes, the most celebrated of the Spanish Protestants, led the way by his *Dialogo de Mercurio y Caron*, where all the great political and religious questions of the first half of the 16th century are discussed and resolved with admirable vigour and freedom. The king in the department of social satire, as in those of literary and political satire, is Quevedo. Nothing escapes his scrutinizing spirit and pitiless irony. All the vices of the society of his time are, in his *Sueños* and many other little pamphlets, remorselessly placed in the pillory and cruelly cut to pieces. While this great satirist, in philosophy a disciple of Seneca, imitates his master even in his style of writing, he is none the less one of the most vigorous and original writers of the 17th century. The only serious defect in his style is that it is too full, not of figures and epithets, but of thoughts. His phrases are of set purpose charged with a double meaning, and we are never sure on reading whether we have taken in all that the author meant to convey. *Conceptism* is the name that has been given to this refinement of thought, which was doomed in time to fall into the ambiguous and equivocal, it must not be confounded with the *cultism* of Góngora, the artifice of which lies solely in the choice and arrangement of words. This new school, of which Quevedo may be regarded as the founder, had its Boileau in the person of Baltasar Gracian, who in 1642 published his *Agudeza y Arte de Ingenio*, in which all the subtleties of conceptism are very exactly reduced to a code. Gracian, who had the gift of sententious moralizing rather than of satire, produced in his *Criticón* animated pictures of the society of his own day, while he also displayed much ingenuity in little collections of political and moral aphorisms which have procured him a great reputation abroad,—*El Heroe*, *El Politico*, *Fernando el Catolico*, *Oraculo Manual y Arte de Prudencia*.

Spanish thought as well as public spirit and all other forms of national activity began to decline towards the

close of the 17th century. The advent of the house of Bourbon, and the increasing invasion of French influence in the domain of politics as well as in literature and science, confirmed this decay by rendering abortive the efforts of a few writers who had remained faithful to the pure Spanish tradition. In the hands of the second rate imitators of Calderon the stage sank ever lower and lower, lyric poetry, already compromised by the pomp and galmatias of Góngora, was abandoned to wretched rhymsters, who tried without success to make up by extravagance of style for meanness of thought. In a word, everything was suffering from anæmia. The first symptoms, not of a revival, but of a certain resumption of intellectual production appear in the department of linguistic study. In 1714 there was created, on the model of the French academies, La Real Academia Española, intended to maintain the purity of the language and to correct its abuses. This Academy set itself at once to work, and in 1726 was able to commence the publication of its dictionary in six volumes folio, the best title of this association to the gratitude of men of letters. The *Gramatica de la Lengua Castellana*, drawn up by the Academy, did not appear till 1771. For the new ideas which were introduced into Spain as the result of more intimate relations with France, and which were in many cases repugnant to a nation for two centuries accustomed to live a self-contained life, it was necessary that fully sanctioned patrons should be found. D. Ignacio de Luzan, well read in the literatures of Italy and France, a disciple of Boileau and the French rhetoricians, yet not without some originality of his own, undertook in his *Poetica* (1737) to expound to his fellow-countrymen the rules of the new school, and, above all, the principle of the famous "unities" accepted by the French stage from Corneille's day onward. What Luzan had done for letters, Benito Feijoo (1676–1764), a Benedictine of good sense and great learning, did for the sciences. His *Teatro Crítico* (1726–1729) and *Cartas Eruditas y Curiosas* (1742–1760), collections of dissertations in almost every department of human knowledge, introduced the Spaniards to the leading scientific discoveries of foreign countries, and helped to deliver them from many superstitions and absurd prejudices. The study of the ancient classics and the department of learned research in the domain of national histories and literatures had an eminent representative in Gregorio Mayans y Siscar (died 1782), who worthily carried on the great traditions of the renaissance, besides publishing good editions of old Spanish authors, he gave to the world in 1757 a *Relôrica* which is still worth consulting and a number of learned memoirs. What may be called the *littérature d'agrément* did not recover much lost ground, it would seem as if the vein had been exhausted. Something of the old Romance picaresque novel came to life again in the *Historia del Famoso Predicador Fray Gerundio de Campazas* of the Jesuit José Francisco de Isla, a biographical romance which is also and above all—to the detriment, it is true, of the interest of the narrative—a satire on the follies of the preachers of the day, the history of Fray Gerundio is merely a pretext, as it were, for displaying and holding up to ridicule the eloquence of the pulpit at the sorry pass to which it had then been brought by the ignorance and bad taste of the Spanish clergy. Isla is known also by his translation of *Gil Blas*, a work which he professed to restore to his native country, trying to make out—unsuccessfully, of course—that Le Sage had no other merit than that of rendering it into French. The lyric poetry of this period is very pale and colourless. Poetry when compared with its dazzling splendour in the preceding century. Nevertheless one or two poets can be named who were possessed of refinement of taste, and whose

collections of verse, though wanting in genuine inspiration, at least show respect for the language and will always meet with some appreciation. At the head of the new school is Juan Menéndez Valdés (1754-1817), and with him are associated the names of P. Diego Gonzales (1733-1794), José Iglesias de la Casa (1748-1791), known especially by his *letrillas*, Nicasio Álvarez de Cienfuegos (1764-1809), and some others. Among the verse writers of the 18th century who produced odes and didactic poetry it is only necessary to mention Leandro Fernández de Moratín (1760-1828) and Manuel José Quintana (1772-1857), but the latter belongs rather to the present century, during the first half of which he published his most important works. The poverty of the period in lyric poetry is even exceeded by that of the stage. Here no kind of comedy or tragical drama arose to take the place of the ancient *comedia*, whose platitudes and absurdities of thought and expression had ended by disgusting even the least exacting portion of the public. The attempt was indeed made to introduce the comedy and the tragedy of France, but the stiff and pedantic adaptations of such writers as Agustín de Montiano y Luyando (1697-1764), Tomás de Iriarte (1750-1791), García de la Huerta, and the well-known economist Gaspar de Jovellanos (1744-1811) were unable to interest the great mass of playgoers. The only one who was really successful in composing on the French pattern some pleasant comedies, which owe much of their charm to the great purity of the language in which they are written, is Leandro Fernández de Moratín, his best pieces are *La Nueva Comedia*, a parody on the extravagant work of Comella, a playwright of the period, *El Viejo y la Niña*, *El Barón*, and particularly *El Si de las Niñas*. It has to be added that the *saynete* was cultivated in the 18th century by one writer of genuine talent, Ramón de la Cruz, nothing helps us better to an acquaintance with the curious Spanish society of the reign of Charles IV than the intermezzos of this genial and light-hearted author.

18th
century

The terrible struggle of the War of Independence (1808-1814), which was destined to have such important consequences in the world of politics, did not exert any immediate influence on the literature of Spain. One might have expected as a consequence of the rising of the whole nation against Napoleon that Spanish writers would have given up seeking their inspiration from those of France, and would have tried to resume the national traditions which had been broken at the end of the 17th century. But nothing of the sort occurred. Not only the *afancesados* (as those were called who had accepted the new régime), but also the most ardent partisans of the patriotic cause, continued in literature to be the submissive disciples of France. Quintana, who in his inflammatory odes preached to his compatriots the duty of resistance and revenge, has nothing of the innovator about him, by his education and by his literary doctrines he remains a man of the 18th century. The same may be said of Francisco Martínez de la Rosa (1789-1848), who, however, from his intercourse with Horace, whom he translated with skill into good Castilian verse, had a greater independence of spirit and a more highly trained and classical taste. And, when romanticism begins to find its way into Spain and to enter into conflict with the spirit and habits of the 18th century, it is still to France that the poets and prose writers of the new school turn, much more than either to England or to Germany. The first decidedly romantic poet of the generation which flourished about 1830 was the duke of Rivas, Ángel de Saavedra (1791-1856), no one succeeded better in reconciling the genius of Spain and the tendencies of modern poetry, his epic poem *El Moro Espósito* and his drama of *Don Álvaro*

ó la Fuerza del Sino belong as much to the old romances and old theatre of Spain as to the romantic spirit of 1830. On the other hand, José de Espronceda (1808-1842), who has sometimes been called the Spanish Musset, savours much less of the soil than the duke of Rivas, he is a quite cosmopolitan romanticist of the school of Byron and the French imitators of Byron, an exclusively lyric poet, he did not live long enough to give full proof of his genius, but what he has left is certainly exquisite. José Zorrilla (born 1817) has a more flexible and exuberant but much more unequal talent than Espronceda, and if the latter has written too little it cannot but be regretted that the former should have produced too much, nevertheless, among a multitude of hasty performances, brought out before they had been matured, his *Don Juan Tenorio*, a new and fantastic version of the legend treated by Tirso de Molina and Molière, will always remain as one of the most curious specimens of Spanish romanticism. In the dramatic literature of this period it is noticeable that the tragedy more than the comedy is modelled on the examples furnished by the French drama of the Restoration, thus, if we leave out of account the play of García Gutiérrez (born 1813) entitled *El Trovador*, which inspired the well-known opera of Verdi, and *Los Amantes de Teruel* of Juan Eugenio Hartzenbusch (born 1806), and a few others, all the dramatic work belonging to this date recalls more or less the manner of the professional playwrights of the boulevard theatres, while on the other hand the comedy of manners still preserves a certain originality and a genuine local colour. Manuel Breton de los Herreros (1796-1873), who wrote as many as a hundred comedies, some of them of the first order after their kind, apart from the fact of their being written in language of great excellence, adheres with great fidelity to the tradition of the 17th century, he is the last of those writers who have preserved the feeling of the ancient *comedia*. One prose writer of the highest talent must be mentioned along with Espronceda, with whom he has in the moral aspect several features in common,—namely, D. José de Larra (1809-1837), so famous by his pseudonym of "Figaro," with which he signed the greater number of his works. Caustic in temper, of a keenly observant spirit, remarkably sober and clear as a writer, he was specially successful in the political pamphlet, the *article d'actualité*, to this category belong his *Cartas de un Pobreco Hablado*, in which he ridicules without pity the vices and oddities of his contemporaries, his reputation is much more largely due to these letters than either to his somewhat feeble play of *Macías* or to his not very attractive novel *El Doncel de Enrique el Doliente*. With Larra must be associated two other humorous writers. The first of these is Ramón Mesonero Romanos, "El Curioso Parlante" (born 1803), whose *Escenas Madrilenas*, although not possessed of the literary value of Larra's articles, give pleasure by their good-natured gaiety and by the curious details they furnish with regard to the contemporary society of Madrid. The other is Serafín Estebanez Calderón, "El Solitario" (1799-1867), who in his *Escenas Andaluzas* sought to revive the manner of the satirical and picaresque writers of the 17th century, in a uselessly archaic language of his own, patched up from fragments taken from Cervantes, Quevedo, and others, he has delineated with a peculiar but somewhat artificial grace various piquant scenes of Andalusian or Madrilenian life. The most prominent literary critics belonging to the first generation of the century were Alberto Lista (1775-1848), whose critical doctrine may be described as a compromise between the ideas of French classicism and those of the romantic school, and Agustín Durán (died 1862), who made it his special task to restore to honour the old literature of Castile, particularly its

romances, which he had studied with unequalled thoroughness, and of which he published highly esteemed collections.

If the struggle between classicists and romanticists continued even after 1830, and continued to divide the literary world into two opposing camps, it is plain that the new generation—that which occupied the scene from 1840 till about 1868—had other preoccupations. The triumph of the new ideas is now assured, only a few reactionaries are still seen to cling to the principles bequeathed by the 18th century. What was now being aimed at was the creation of a new literature which should be truly national and no longer a mere echo of that beyond the Pyrenees. To the question whether contemporary Spain has indeed succeeded in calling into existence such a literature, we may well hesitate to give an affirmative answer. It is true that in every species of composition, the gravest as well as the lightest, it can show works of genuine talent, but many of them are strikingly deficient in originality, all of them either bear unmistakable traces of imitation of foreign models, or show (more or less happily) the imprint of the older literature of the 17th century, to which the historical criticism of Duran and the labours of various other scholars had given a flavour of novelty. With this observation before him, the student can divide the authors of this period into two groups,—the one composed of those who, won by modern ideas, are more or less liberal in politics, and draw their inspiration in all they write from France or from what they are able to assimilate of other literatures through France, the other consisting of ultra-conservatives, whose dream in every sphere—letters, art, and politics—is the restoration of the Spain of the past. Nowhere does this antagonism manifest itself more clearly than in the drama. A play of Aureliano Fernandez Guerra might have been conceived and written by a contemporary of Lope or of Calderon, while a comedy of Adelardo Lopez de Ayala is moulded in the pattern given by the younger Dumas and by Augier. In the department of romance, on the other hand—much neglected by the writers of the first half of the century—the Spaniards have recovered something of the genius of Cervantes and their 17th century *novelas picarescas*. The art of constructing a story and of telling it in an agreeable way, which seemed for a long time to have been lost, is recovered in such authors as Fernan Caballero, Antonio de Trueba, Pedro Antonio de Alarcón, Juan Valera, Perez Galdos, and Pareda. These novelists are far from alike in method or in spirit, how widely separated, for example, are the somewhat banal facility and the sentimental catholicism of Fernan Caballero on the one hand, and the searching psychological analysis and the fine scepticism of Juan Valera on the other. But all have this in common, that they understand how to interest their readers, and how to make their characters live and speak. Incontestably the novel is the triumph of contemporary Spanish literature, it is almost the only kind of composition that actually lives with a life of its own and makes steady progress. One cannot say as much of lyric poetry, represented feebly enough by Ramon de Campoamor, Nuñez de Arce, and some others. Deficient inspiration, diffuseness of style, and want of precision in language characterize them all, it is unfortunately very easy to make mediocre verses in Spanish, and too many people give themselves over to the pursuit. Passing from the literature of amusement, we have still some very distinguished names to enumerate. Philosophy, indeed, has but one representative of merit, the traditionalist Jaime Balmes,—for the Krausist school, an importation from Germany, may be ignored here,—but history and literary criticism have been cultivated during the last thirty years or so with genuine success. Modesto Lafuente is in some sort the Mariana of the 19th

century, much inferior as a writer to the celebrated Jesuit, he has, however, always manifested the same passion for his subject, the same persevering determination to raise a worthy monument of his fatherland, his *Historia de España*, in spite of all its defects, deserves respect, and is at least readable. Although primarily a politician, Antonio Cánovas del Castillo has many of the qualities which go to the making of a good historian, he has evinced greater acuteness and larger acquirements than Lafuente, and his *Ensayo sobre la Casa de Austria en España*, founded upon a careful examination of a large number of documents, gives evidence of a correct judgment and praiseworthy impartiality. The literary history of old Spain has been treated in a masterly manner by Aureliano Fernandez Guerra in various studies devoted to the great writers of the 17th century, notably Quevedo, and also quite recently by a young and talented scholar, Marcelino Menéndez Pelayo, whose *Historia de las Ideas Estéticas en España*, a work as solid in its substance as it is pure in its style, would do honour to any veteran in literature. As regards criticism of contemporary literature, no one shows more spirit and taste than Juan Valera, whose delicate Andalusian nature has been matured by a refining education and by an adequate knowledge of foreign literatures.

Bibliography.—The base of the student's operations is always the great work of Nicolas Antonio, *Bibliotheca Hispana Velus* and *Bibliotheca Hispana Nova*, in the revised and completed edition of Francisco Perez Bayer, Tomas Antonio Sanchez, and Juan Antonio Pellicer (Madrid, 1783-88, 4 vols. fol.). The student can afford to disregard all the general histories which preceded Ticknor's *History of Spanish Literature* (New York, 1849, 3 vols. 8vo, 4th ed., Boston, 1872, 3 vols. 8vo), a work of solid value, especially from the bibliographical point of view, it is quite indispensable that the reader should consult also the Spanish translation by D. Pascual de Gayangos and Enrique de Vedia (Madrid, 1851-56) and the German translation of Julius with some important additions by Ferdinand Wolf (Leipzig, 1852-67). Nothing can be said in favour of the French translation by J. G. Magnabal (Paris, 1864-72). The *Historia Crítica de la Literatura Española* of José Amador de los Ríos (Madrid, 1861-65, 7 vols. 8vo), although deficient in criticism and full of errors in fact, supplies some useful information as to the period prior to the 16th century, with which it exclusively deals. Menéndez Pelayo's *Historia de las Ideas Estéticas en España* (Madrid, 1884-86, 3 vols. 8vo), already referred to, is very instructive. For the 18th century, Leopoldo A. de Cueto's "*Bosquejo Histórico Crítico de la Poesía Castellana en el Siglo xviii.*" prefixed to the first vol. of Rivadeneyra's *Poetas Líricos del Siglo xviii.*, is indispensable. For the 19th century there is not as yet any satisfactory work dealing with the literature as a whole, that of M. G. Hubbard, *Histoire de la Littérature Contemporaine en Espagne* (Paris, 1876, 1 vol. 8vo), although superficial and inaccurate, is useful in the absence of anything better. Some descriptions of Castilian literature have been specially studied with care and competence, notably the drama, on which we have two thorough works,—Frederick von Schack's *Geschichte der dramatischen Literatur u. Kunst in Spanien* (Frankfort-on the Main, 1846-54, 3 vols. 8vo), unfortunately now much behindhand, and in no way improved in this respect in the Spanish translation now in course of publication at Madrid under the superintendence of Eduardo de Mier, and Cayetano Alberto de la Barrera's excellent *Catálogo Bibliográfico y Biográfico del Teatro Antiguo Español* (Madrid, 1860, large 8vo). On the Castilian literature of the Middle Ages, the works to be consulted are Ferdinand Wolf's *Studien zur Geschichte der Spanischen u. Portugiesischen Nationalliteratur* (Berlin, 1859, 1 vol. 8vo) and Manuel Milá y Fontanals's *De la Poesía Heroico-Popular Castellana* (Barcelona, 1874, 1 vol. 8vo).

II. CATALAN LITERATURE.—Although the Catalan language is simply a branch of the southern Gallo-Roman, Middle Ages, the literature, in its origin at least, ought to be considered as a mere appendix of that of Provence. Nay more, until about the second half of the 13th century there existed in the Catalan districts no other literature than the Provençal, and the poets of north-eastern Spain used no other language than that of the troubadours. Guillem de Bergadan, Ue de Mataplana, Ramon Vidal de Besalú, Guillem de Cervera, Serveri de Girona, and several other verse writers of a still more recent date are all genuine Provençal poets, in the same sense as are those of

Limousin, Quercy, or Auvergne, since they write in the *langue d'oc* and make use of all the forms of poetry cultivated by the troubadours north of the Pyrenees. Ramon Vidal (end of 12th century and beginning of 13th) was a grammarian as well as a poet, his *Rasos de Trobar* became the basis for the Catalan poetry written in Provençal, which he called *Lemosin*, a name still kept up in Spain to designate, not the literary idiom of the troubadours only, but also the local idiom—Catalan,—which the Spaniards choose to consider as derived from the former. The influence of R. Vidal and other grammarians of his school, as well as that of the troubadours we have named, lasted for a very long time, and even after Catalan prose—an exact reflexion of the spoken language of the south east of the Pyrenees—had given evidence of its vitality in some considerable works, the Catalan poetry remained faithful to the Provençal tradition. From the combination of spoken Catalan with the literary language of the troubadours there arose a sort of composite idiom, which has some analogy with the Franco-Italian current in certain parts of Italy in the Middle Ages, although in the one case the elements of the mixture are more distinctly apparent than are the romances of France and the romance of Italy in the other. The poetical works of Raymond Lully (Ramon Lull) (died 1315) are among the oldest examples of this Provençalized Catalan, one has only to read the fine piece entitled *Lo Desconort* ("Despair"), or some of his stanzas on religious subjects, to apprehend at once the eminently composite nature of that language. Muntaner in like manner, whose prose is exactly that spoken by his contemporaries, becomes troubadour when he writes in verse, his *Sermó* on the conquest of Sardinia and Corsica (1323), introduced into his *Chronicle* of the kings of Aragon, exhibits linguistically quite the same mixed character as is found in Lully, or, we may venture to say, in all the Catalan verse writers of the 14th century. These are not very numerous, nor are their works of any great merit. The majority of their compositions consist of what were called *noves rimades*, that is, stories in octosyllabic verse in rhymed couplets. There exist poems of this class by Pere March, by a certain Torroella, by Bernat Metge (an author more celebrated for his prose), and by others whose names we do not know, among the works belonging to this last category special mention ought to be made of a version of the romance of the *Seven Sages*, a translation of a book on good breeding entitled *Fugetus*, and certain tales where, by the choice of subjects, by various borrowings, and even occasionally by the whole sale introduction of pieces of French poetry, it is clearly evident that the writers of Catalonia understood and read the *langue d'oc*. Closely allied to the *noves rimades* is another analogous form of versification—that of the *codalada*, consisting of a series of verses of eight and four syllables, rhyming in pairs, still made use of in one portion of the Catalan domain (Majorca).

of 15th
century

The 15th century is the golden age of Catalan poetry. At the instigation and under the auspices of John I (1387–1395), Martin I (1395–1410), and Ferdinand I (1410–1416), kings of Aragon, there was founded at Barcelona a consistory of the "Gay Saber," on the model of that of Toulouse, and this official protection accorded to poetry was the beginning of a new style much more emancipated from Provençal influence. It cannot be denied, indeed, that its forms are still of foreign importation, that the Catalan verse writers accept the prescriptions of the *Leys d'Amor* of Guillaume Molnier, and the names which they gave to their *cobles* (stanzas) are all borrowed from the same *art de trobar* of the school of Toulouse, but, a very noteworthy fact, their language begins to rid itself more and more of Provençalisms and

tends to become the same as that of prose and of ordinary conversation. With Pere and Jaume March, Jordi de Sant Jordi, Johan de Masdovelles, Francesch Ferrer, Pere Torroella, Pau de Bollviure, Antoni Vallmanya, and, above all, the Valencian Ausias March (died 1459), there flourished a new school, of which the *éclat* lasted till the end of the 15th century, and which, as regards the form of its versification, is distinguished by its almost exclusive employment of eight-verse *cobles* of ten syllables, each with "crossed" or "chained" rhymes (*cobla creuada* or *encadenada*), each composition ending with a *tornada* of four verses, in the first of which the "device" (*divís* or *senyal*) of the poet is given out. The greater number of these poems are still unedited or have only recently been extracted from the *cançoners*, where they had been collected in the 15th century. Ausias March alone, the most inspired, the most profound, but also the most obscure of the whole group, had the honour to be printed in the 16th century, his *cants d'amor* and *cants de mort* contain the finest verses ever written in Catalan, but the poet fails to keep up to his own high level, and by his studied obscurity occasionally becomes unintelligible to such a degree that one of his editors accuses him of having written in Basque. Of a wholly different class, and in quite another spirit, is the *Libre de les Dones* of Jaume Roig (died 1478), a Valencian also, like March, this long poem is a *nova rimada*, only *comediada*, that is to say, it is in quadrisyllabic instead of octosyllabic verse. A bitter and caustic satire upon women, it purports to be a true history,—the history of the poet himself and of his three unhappy marriages in particular. Notwithstanding its author's allegations, however, the *Libre de les Dones* does not seem to be other than a fiction, but it derives a very poignant interest from its really authentic element, its vivid picture of the Valencia of the 15th century and the details of the manners of that time. After this bright period of efflorescence Catalan poetry rapidly fell off, a decline due more to the force of circumstances than to any fault of the poets. The union of Aragon with Castile, and the resulting predominance of Castilian throughout Spain, inflicted a death blow on Catalan literature, especially on its artistic poetry, a kind of composition more ready than any other to avail itself of the triumphant idiom which soon came to be regarded by men of letters as the only noble one, and alone fit to be the vehicle of elevated or refined thoughts. The fact that a Catalan, Juan Boscán, inaugurates in the Castilian language a new kind of poetry, and that the Castilians themselves regard him as the head of a school, is important and characteristic, the date of the publication of the works of Boscán (1543) marks the end of Catalan poetry.

The earliest prose works in Catalan are later indeed than the poems of the oldest Catalan troubadours of the Provençal school, not dating farther back than from the close of the 13th century, but they have the advantage of being entirely original, their language is the very language of the soil which we see appearing in charters from about the time of the accession of James I (1213). This is true especially of the chronicles, a little less so of the other writings, which, like the poetry, have difficulty in escaping the influence of the more polished dialect of the country to the north of the Pyrenees. Its chronicles are the best ornament of medieval Catalan prose. Four of them,—that of James I, apparently reduced to writing a little after his death (1276) with the help of memoirs dictated by himself during his lifetime, that of Bernat Des Clot, which deals chiefly with the reign of Pedro III. of Aragon (1276–1286), that of Ramon Muntaner (first half of the 14th century), relating at length the expedition of the Catalan company to the Morea and the conquest

Prose of
13th–15th
centuries

of Sardinia by James II., finally that of Pedro IV, The Ceremonies (1336-1387), genuine commentaries of that astute monarch, arranged by certain officials of his court, notably by Bernat Des Coll,—these four works are distinguished alike by the artistic skill of their narration and by the quality of their language, it would not be too much to liken these Catalan chroniclers, and Muntaner especially, to Villehardouin, Joinville, and Froissart. The Doctor Illuminatus, Raymond Lully, whose acquaintance with Latin was very poor,—his philosophical works were done into that language by his disciples,—wrote in a somewhat Provençalized Catalan various moral and propagandist works,—the romance *Blanquerna* in praise of the solitary life, the *Libre de les Maravelles*, into which is introduced a "bestiary" taken by the author from *Kahlak and Dimnag*, and the *Libre del Orde de Cavalleria*, a manual of the perfect knight, besides a variety of other treatises and opuscula of minor importance. The majority of the writings of Lully exist in two versions,—one in the vernacular, which is his own, the other in Latin, originating with his disciples, who desired to give currency throughout Christendom to their master's teachings. Lully—who was very popular in the lay world, although the clergy had a low opinion of him and in the 15th century even set themselves to obtain a condemnation of his works by the Inquisition—had a rival in the person of Francesch Ximenez or Eximeniz, a Franciscan, born at Gerona some time after 1350. His *Crestia* (printed in 1483-84) is a vast encyclopædia of theology, morals, and politics for the use of the laity, supplemented in various aspects by his three other works—*Vida de Jesu Christ*, *Libre dels Angels*, and *Libre de les Dones*, the last-named, which is at once a book of devotion and a manual of domestic economy, contains a number of curious details as to a Catalan woman's manner of life and the luxury of the period. Lully and Eximeniz are the only Catalan authors of the 14th century whose works written in a vulgar tongue had the honour of being translated into French shortly after their appearance.

We have chiefly translators and historians in the 15th century. Antoni Canals, a Dominican, who belongs also to the previous century, translates into Catalan Valerius Maximus and a treatise of St Bernard, Bernat Metge, himself well-versed in Italian literature, presents some of its great masters to his countrymen by translating the *Griselidis* of Petrarch, and also by composing *Lo Somni* ("The Dream"), in which the influence of Dante, of Boccaccio, and, generally speaking, of the Italy of the 13th and 14th centuries is very perceptible. The *Feyts d'Armes de Catalunya* of Bernat Boades, a knightly chronicle brought to a close in 1420, reveals a spirit of research and a conscientiousness in the selection of materials which are truly remarkable for the age in which it was written. On the other hand, Pere Tomich, in his *Histoires & Conquestes del Reyalme d'Aragó* (1438), carries us back too much to the manner of the mediæval chroniclers, his credulity knows no bounds, while his style has altogether lost the naive charm of that of Muntaner. To the list of authors who represent the leading tendencies of the literature of the 15th century we must add the name of Johanot Martorell, a Valencian, author of the celebrated romance of chivalry *Tirant lo Blanch* (finished in 1460), which the reader has nowadays some difficulty in regarding as that "treasury of contentment" which Cervantes will have it to be.

16th-18th
centuries—

With the loss of political independence in the Catalan countries Catalan fell to the rank of a patois and was written less and less, lettered persons ceased to cultivate it, and the upper classes, especially in Valencia, owing to the proximity of Castile, soon affected to make no further use of the local speech except in familiar conversation. The 16th century,

in fact, furnishes literary history with hardly more than a single poet at all worthy of the name—Pere Serafi, some of whose pieces, in the style of Ausias March, but less obscure, are graceful enough and deserve to live, his poems were printed at Barcelona in 1565. Prose is somewhat better represented, but, to tell the truth, it is only the erudite who persist in writing in Catalan,—antiquaries and historians like Pere Miguel Carbonell, compiler of the *Chroniques de Espanya* (1547), Francesch Tarafa, Pere Anton Beuter, also chroniclers, and some others not so well known. In the 17th and 18th centuries the decadence becomes still more marked. A few scattered attempts to restore to the Catalan, now more and more neglected by men of letters, some of its old life and brilliance, fail miserably. Neither Hieronim Pujades the historian, author of a *Coronica Universal del Principat* (Barcelona, 1609), nor even Dr Vicens Garcia, rector of Vallfogona (1582-1623), a verse-writer by no means destitute of verve or humour, but whose literary talent and originality have been very greatly exaggerated by the Catalans of the present day, was able to bring back his countrymen to a cultivation of the local idiom. Some sermons, some lives of saints, some books of devotion, some relations and complaints for the use of the people, exhaust the catalogue of everything written in Catalan throughout the whole area of its domains down to the beginning of the present century, not a single book of importance can be mentioned. Writers who were Catalan by birth had so completely unlearned their mother-tongue that it would have seemed to them quite inappropriate, and even ridiculous, to make use of it in serious works, so profoundly had Castilian struck its roots in the eastern provinces of Spain, and so thoroughly had the work of assimilation been carried out to the advantage of the official language of the court and of the Government.

In 1814 appeared the *Gramática y Apologia de la P. Llengua Catalana* of Joseph Pau Ballot y Torres, which may be considered as marking the origin of a genuine renaissance of the grammatical and literary study of Catalan. Although the author avows no object beyond the purely practical one of giving to strangers visiting Barcelona for commercial purposes some knowledge of the language, the enthusiasm with which he sings the praises of his mother-tongue, and his appended catalogue of works which have appeared in it since the time of James I., sufficiently show that this was not his only aim. In point of fact the book, which is entitled to high consideration as being the first systematic Catalan grammar, written, too, in the despised idiom itself, had a great influence on the authors and literary men of the principality. Under the helping influence of the new doctrines of romanticism twenty years had not passed before a number of attempts in the way of restoring the old language had made their appearance, in the shape of various poetical works of very unequal merit. The *Oda á la Patria* (1833) of Buenaventura Carlos Aribau is among the earliest if not actually the very first of these, and it is also the best, the modern Catalan school has not produced anything either more inspired or more correct. Following in the steps of Aribau, Joaquin Rubió y Ors (*Lo Gayter del Llobregat*), Antonio de Bofarull (*Lo Coblador de Moncada*), and soon afterwards a number of other verse writers took up the lyre which it might have been feared was never to sound again since it fell from the hands of Ausias March. The movement spread from Catalonia into other provinces of the ancient kingdom of Aragon, the appeal of the Catalans of the principality was responded to at Valencia and in the Balearic Isles. Later, the example of Provence, of the *félibrige* of the south of France, accelerated still further this renaissance movement, which received official recogni-

tion in 1859 by the creation of the *jocs florals*, in which prizes are given to the best competitors in poetry, of whom some succeed in obtaining the diploma of *metge en gay saber*. It is of course impossible to foresee the future of this new Catalan literature,—whether it is indeed destined for that brilliant career which the Catalans themselves anticipate. In spite of the unquestionable talent of poets like Mariano Aguiló (Majorca), Teodoro Llorento (Valencia), and, among the younger of them, Jacinto Vordaguer (Catalonia), author of an epic poem *Atlantida* and of very fascinating *Cants Místics*, it is by no means certain that this generation will be succeeded by another to follow in its footsteps, or that such a restoration of a provincial literature has much chance of permanence at the very moment when all the peoples of Europe are tending rather towards unity and centralization in the matter of language. At all events, in order to secure even a comparative success for such a revival, it would be well if the language serving as its instrument were some what more fixed, and if its writers would no longer hesitate, as they at present do, between a pretentious

archaism and the incorrectness of the most vulgar colloquialism. The few attempts of modern Catalans in the direction of romance writing and dramatic composition have not hitherto been particularly felicitous, and have not led to anything noteworthy.

SPALATIN, GEORGE (1484-1545) George Burkhardt, a subordinate figure of some interest in the history of the Reformation in Germany, was born on January 17, 1484, at Spalt (whence he assumed the name Spalatinus), about 25 miles from Nuremberg, where his father was an artisan

He went to Nuremberg for education when he was thirteen years of age, and two years afterwards to the university of Erfurt, where he took his bachelor's degree within a year, in 1499. There he attracted the notice of Marschalk, the most influential professor, who made Spalatín his amanu-

ensis and took him to Wittenberg. In 1507 Spalatin went to Erfurt to study jurisprudence, was recommended to Mutianus, and was welcomed by the little band of German humanists of whom Mutianus was chief. His friend got him a post as teacher in the monastery at Georgenthal, and before this he had received a church appointment in the neighbouring Hohenkirchen. In 1508 he was ordained priest by Bishop John von Laasphe, who had ordained Luther. He had no great love for convent or pastoral work, and in 1509 Mutianus recommended him to Frederick the Wise, the elector of Saxony, who employed him to act as tutor to his son, the future elector, John Frederick. Spalatin speedily gained the confidence of the famous elector, who employed him in many affairs. He sent him to Wittenberg in 1511 to act as tutor to his nephews, and procured for him a canon's stall in Altenberg. In 1512 the elector made him his librarian. Thus brought him into correspondence with a large number of literary men, and he began to collect all kinds of literary and especially of historical information, of which he made extensive use later in his chronicles. He was promoted to be court chaplain and confidential secretary to the elector, and took charge of all his private and public correspondence. He thus became one of the most important men at the electoral court, which then was the centre of German life.

Spalatin had never cared for theology, and, although a priest and a preacher, had been a mere humanist. It was to Luther that he owed his awakening to the reality of a spiritual life. How he first became acquainted with the reformer it is impossible to say—probably at Wittenberg, but Luther from the first exercised a great power over him, and became his chief counsellor in all moral and religious matters. His letters to Luther have been lost, but Luther's answers remain, and are extremely interesting. Spalatin was Luther's devoted friend during the stormiest days of the Reformation, and was the means of bringing the great elector to take the side of the outspoken professor in his university of Wittenberg. He read Luther's writings to the elector, and translated for his benefit those in Latin into German. He accompanied Frederick to the diet of Augsburg, and shared in the negotiations with the papal legates, Cajetan and Miltitz. He was with the elector when Charles was chosen emperor and when he was crowned. He was with his master at the diet of Worms. In short, he stood beside Frederick as his confidential adviser in all the troubled diplomacy of the earlier years of the Reformation. Singularly cautious, perhaps timid, before the crisis came and while it could be averted, Spalatin found courage when the crisis had come. He would have dissuaded Luther again and again from publishing books or engaging in overt acts against the papacy, but, when the thing was done, none was so ready to translate the book, or to justify the act.

On the death of Frederick the Wise, Spalatin was as much engaged in diplomatic service as before, but he no longer lived at court. He went into residence as canon at Altenberg, and incited the chapter to institute reforms somewhat unsuccessfully. He married in the same year. During the later portion of his life, from 1526 onwards, he was chiefly engaged in the visitation of churches and schools in electoral Saxony, reporting on the confiscation and application of ecclesiastical revenues. His practical experience in German affairs made him very successful in his delicate task, and he was asked to undertake the same work for Albertine Saxony. He was also permanent visitor of Wittenberg university, and made an annual report of its condition to the elector. Shortly before his death he fell into a state of profound melancholy, and died January 16, 1545, at Altenberg.

Spalatin left behind him a large number of literary remains, both published and unpublished. His original writings are almost

all historical. A list of them may be found in Seelheim's *Geogr. Spalatin als sächs. Historiograph*, 1876. There is no good life of Spalatin, nor can there be until his letters have been collected and edited, a work still to be done.

SPALATO (Slav. *Split*), a city of Dalmatia, at the head of one of the thirteen departments (area 730 square miles, population in 1880 31,003), is situated on the seaward side of a peninsula lying between the Gulf of Braza and the Gulf of Salon. Though not the capital, it is the most important city in the principality, is the see of a bishop, has a valuable museum of antiquities, and carries on an extensive trade in wine and oil. Since 1879 it has been the terminus of a railway running northwards to Sebenico and Smeric. Built on the low ground at the head of a beautiful bay, and thrown into relief by a back ground of picturesque hills rising close behind, Spalato has a striking sea-front, in which the leading feature is still the ruined facade of the great palace of Diocletian, erected in 303 A.D., to which the city owes its origin. In ground plan this is almost a square, with a quadrangular tower at each of the four corners. "Its facade corresponds nearly with the four point of the compass. The south front (towards the harbour) measures 521 feet, or, with the towers, 545 feet 5 inches, and the eastern and western sides are each 705 feet 8 inches." (Wilkinson). The area included is 318,175 square feet, or, comprising the towers, 352,611 square feet, a little more than eight acres, or rather less than the area of the Leceonal. There were four principal gates, with four street meetings in the middle of the quadrangle, after the style of a Roman camp. The eastern gate (Porta Aenea) is destroyed, but, though the side towers are gone, the main entrance of the building, the beautiful Porta Aurea, in the west front, is still in fairly good preservation. The streets were lined with massive arcades. The vestibule now forms the Piazza del Duomo or public square, to the north-east of this lies the mausoleum (not, as the older antiquaries had it, the temple of Jupiter), which has long been the smallest and darkest of cathedrals, and to the south-east is the temple of Asculanus, which served originally as a kind of court chapel and has long been transformed into a baptistery. Architecturally the most important of all the many striking features of the palace is the arrangement in the vestibule by which the supporting arches spring directly from the capitals of the large granite Corinthian columns. This, as far as the known remains of ancient art are concerned, is the first instance of such a method, and thus, in Mr Freeman's words, "all Gothic and Romanesque architecture was in embryo in the brain of Jovius or his architect."

The name Spalato, or Spalatro (a very old spelling), which used to be explained as a corruption of Salon, Palatium, is pretty certainly of different origin—the oldest form extant being *Aspalathum* (Constantino Porphyrogenitus) and early variants *Spalathon*, *Spalathron*, *Spalathrum* (*Germ. Rar.*). Dr Lavis suggests a connexion with *Aspalathus* (the name of a prickly shrub) or perhaps with *Asphaltus*. Not long after Diocletian's death the buildings seem to have been turned into an imperial cloth factory, and as most of the workers were women we find it called a *syncretium* (*Névia*). About 4 miles from the palace lay the ancient city of Salona (*Salōna* or *Salōniat*), which consisted of two parts, the earlier Roman city to the west and a later portion incorporated previous to the time of the Antonines. There are still remains at Salona of ancient city walls, an amphitheatre, &c., and a long line of walls extending from the western side of the city for a mile and more nearly along the present road to Trun (*Tragurium*). The purpose of this line of walls is not evident, and the date of its construction has been the subject of much discussion. Mr Freeman is disposed to consider them Roman workmanship.

Salona in its best days was one of the chief ports of the Adriatic, on one of the most central sites in the Roman world. Made a Roman colony after its second capture by the Romans (B.C. 78), it appears as *Colonia Martia Julia* and *Colonia Claudia Augusta* *Prætoriana*, and bears at different periods the titles of *respublica*, *conventus*, *metropolis*, *præfectura*, and *prætorium*. In Christian times it became a bishop's see, and St Domo or Domnius, its first bishop, still gives his name to the cathedral of Spalato. The city

was taken by Odoacer in 481 and by Totila in the 6th century. Recovered by Justinian in 535, it was in 544 and 552 the starting point of Belisarius and Narses for their Italian expeditions. In the 7th century Salona was completely destroyed by the Avars, but the empty palace of Diocletian afforded an asylum for its inhabitants. The limits of the building proved sufficient for the new city up to the time that it passed under Hungarian and Venetian protection. Hungarian additions may still be seen above the Porta Aurea, and the large octagonal tower bears the name of Torre d'Harveyo from the Bosnian general who was created duke of Spalato by Ladislaus. The Venetians enclosed the town with regular curtains and bastions in 1645-1670. About 1807-1809 the castle was dismantled and parts of the walls were thrown down.

See Robert Adam, *Notes of the Palace of Diocletian*, 1764; Casanova and Lavallée, *Voyage Pittoresque et Historique de l'Isle de Dalmatie*, 1802; Wilkinson, *Dalmatia and Montenegro*, 1818; Freeman *Historical Essays*, 3d series, 1879 and *Subject and Neighbour Land of Venice* 1881. Both the first mentioned works contain magnificent views and restorations of the architecture of the palace.

SPALDING, a market-town of Lincolnshire, England, in the Parts of Holland, is situated on the river Wolland, and on the Great Northern and Great Eastern Railways, 93 miles from London. The town, standing in the heart of the Fens, is the centre of a rich agricultural district. Amongst the public buildings are five churches, the Johnson hospital (1881), the corn exchange (1856-57), the buildings of the mechanics' institute and of the Christian association and literary institute, and the district union-house. The parish church of St Mary and St Nicholas was built in 1284 and restored in 1865-66. The adjoining lady chapel (St Mary and St Thomas a Becket) was built in 1315, in 1588 it was appropriated for the grammar school endowed in 1568 by John Blunko and again in 1588 by John Gamlyn. A new grammar school was erected in 1881. Spalding has had a prison for upwards of 600 years, the present building, erected in 1824-25, was closed in 1884. The Wolland is crossed at Spalding by two stone bridges. The existing high bridge, constructed in 1838, took the place of a wooden erection dating from the end of the 17th century, this last was built on the site of an older Roman bridge of two arches, the foundations of the centre pier of which were disclosed when the wooden bridge was constructed. The population of the town in 1871 was 9111, and in 1881 9260.

In 1051 Thorold of Bockenhale (now Bucknall, near Horncastle) gave his castle of Spalding and the chapel attached to it as a cell or monastery for the Benedictines of Clewland. Out of this grew the priory, which, however, was dissolved in 1535, the last fragments of its ruins were removed in 1832. About two miles north-east of Spalding stands the ruined chapel of Wykeham, dedicated to St Nicholas and built in 1311 by Prior Clement Hatfield. The building is of the Decorated period, and has been roofless since 1782, its interior dimensions are 43 feet long by 22 feet wide, the walls are 44½ feet high. Each side contains three three-light windows with moulded flowing tracery, and each end one four-light window of similar character. The only one which retains its original mullions and tracery is the centre window on the south side. After the Conquest the estates and priory of Spalding were given by William I to Ivo Taillebois, who found such a stout antagonist in Hereward the Wake, lord of Branne or Bourn.

SPALDING, WILLIAM (1809-1859), logician and literary historian, was born in Aberdeen in 1809. After a thorough education at the grammar school and at Marischal College there, he came to Edinburgh in 1830, where he was called to the bar in 1833. In that year he published a *Letter on Shakespeare's Authorship of the Two Noble Kinsmen*, which, by its critical acumen and the knowledge of the old dramatists which it displayed, attracted the notice of Jeffrey and procured the author an invitation to become a contributor to the *Edinburgh Review*. Before settling down to the business of the bar he undertook a prolonged Continental tour. He was absent fifteen months, the greater part of the time being spent in Italy, and in 1841 the fruits of his stay appeared in three volumes entitled *Italy and the Italian Islands from the Earliest Ages to the Present Time*. This learned and comprehensive work went through five editions in a few years. His attempts to gain a legal practice not proving

successful, he became a candidate in 1838 for the chair of rhetoric in Edinburgh university, which he held till 1845, when he was appointed professor of logic in the university of St Andrews. He held the latter post till his death on the 16th November 1859.

Besides the works already mentioned, and various articles contributed to the *Edinburgh Review* and *Blackwood's Magazine*, he was the author of a concise *History of English Literature*, which has many merits and has been much used as a text book. He also wrote the articles "Logic" and "Rhetoric" (as well as a number of literary biographies) for the eighth edition of the *Encyclopædia Britannica*. The former article, written mainly on Hamiltonian lines, constitutes a systematic treatise on Formal Logic, and is honourably distinguished by its clear scientific exposition. By these two articles and his *History of English Literature* Spalding is chiefly remembered.

SPALLANZANI, LAZARO (1729-1799), is one of the most important and certainly also one of the most picturesque figures in the history of science during the 18th century. Born at Scandiano in Modena in 1729, he was at first educated by his father, who was an advocate. At the age of fifteen he was sent to the Jesuit college at Reggio di Modena, and was pressed to enter that body. He went, however, to the university of Bologna, where his famous kinswoman Laura Bassi, was professor, and it is to her influence that his scientific impulse has been usually attributed. With her he studied natural philosophy and mathematics, and gave also great attention to languages, both ancient and modern, but soon abandoned the study of law, and afterwards took orders. His reputation soon widened, and in 1754 he became professor of logic, metaphysics, and Greek in the university of Reggio, and in 1760 was translated to Modena, where he continued to teach with great assiduity and success, but devoted his whole leisure to natural science. He declined many offers from other Italian universities and from St Petersburg until 1768, when he accepted the invitation of Maria Theresa to the chair of natural history in the university of Pavia, which was then being reorganized. He also became director of the museum, which he greatly enriched by the collections of his many journeys along the shores of the Mediterranean. In 1785 he was invited to succeed Vallisneri at Padua, but to retain his services his sovereign doubled his salary and allowed him leave of absence for a visit to Turkey, where he remained nearly a year, and made many observations, among which may be noted those of a copper mine in Chalki and of an iron mine at Principi. His return home was almost a triumphal progress. At Vienna he was cordially received by Joseph II., and on reaching Pavia he was met with acclamations outside the city gates by the students of the university. During the following year his students exceeded five hundred. His integrity in the management of the museum was called in question, but a judicial investigation speedily cleared his honour, to the satisfaction even of his accusers. In 1788 he visited Vesuvius and the volcanoes of the Lipari Islands and Sicily, and embodied the results of his researches in a large work published four years later. He died from an apoplectic seizure, in 1799, at the age of seventy.

His indefatigable exertions as a traveller, his skill and good fortune as a collector, his brilliance as a teacher and expositor, and his keenness as a controversialist no doubt aid largely in accounting for Spallanzani's exceptional fame among his contemporaries, yet greater qualities were by no means lacking. His life was one of incessant eager questioning of nature on all sides, and his many and varied works all bear the stamp of a fresh and original genius, capable of stating and solving problems in all departments of science,—at one time finding the true explanation of "ducks and drakes" (formerly attributed to the elasticity of water) and at another helping to lay the foundations of our modern vulcanology and meteorology. His main discoveries, however, were in the field of physiology. He wrote valuable and suggestive papers on respiration, on the senses of bats, &c., while his highly important controversy with Needham and Buffon, in which he experimentally disproved the occurrence of spontaneous generation, has been already

referred to under *ADIGESTION*. In this regard also he was led to pay considerable attention to the infusorial animalcules. His great work, however, is the *Dissertation de Finca Animale e Vegetale* (2 vols., 1780). Here he first interpreted the process of digestion, which he proved to be no mere mechanical process of trituration, but one of actual solution, taking place primarily in the stomach, by the action of the gastric juice. Verifying this by the important experiment of artificial digestion outside the stomach in sealed tubes, he was attacked by John Hunter, but emerged victorious from the encounter. Of no less importance are his researches on reproduction, in which he experimentally settled the relative functions of the ovum and the spermatozoon. See *REPRODUCTION*.

SPANDAU, a strongly-fortified town in the province of Brandenburg, Prussia, is situated at the confluence of the Havel and Spree, 8 miles to the north-west of Berlin. It has recently been converted into a fortress of the first class, and is now the key of the defences of the capital. The Julius tower in the citadel, which is surrounded by water, contains the imperial war treasure (*Reichskriegsschatz*),—a sum of £6,000,000 in gold, kept in readiness for any warlike emergency. Besides numerous barracks, Spandau contains various military establishments appropriate to an important garrison town, and its chief industries are connected with the preparation of munitions of war. The Government factories for the manufacture of small arms, artillery, gunpowder, &c., cover upwards of 200 acres, and employ about 4000 workmen. The other industries are not very important, they comprise miscellaneous manufactures, fishing, boat-building, and some shipping on the Havel. The population in 1885, including the garrison of nearly 4000 men, was 31,463.

Spandau is one of the oldest places in the Altmark, and received town rights in 1232. It afterwards became a favourite residence of the Hohenzollern electors of Brandenburg, and was fortified in 1577–83. In 1635 it surrendered to the Swedes, and in 1806 to the French. A short investment in 1813 restored it to Prussia. The population in 1816 was 6250.

SPANGENBERG, AUGUST GOTTLIEB (1704–1792), Count Zinzendorf's successor, and bishop of the Moravian Brethren, was born July 14, 1704, at Klettenberg, on the south of the Harz Mountains, where his father was court-preacher, and ecclesiastical inspector of the *grafschaft* of Hohenstein. Left an orphan at the early age of ten, he was sent to the excellent high school at Ilfeld, and passed thence (1722), in poorest circumstances, to Jena to study law. Prof. Buddens received the poor youth into his family, and a "stipendium" was procured for him. Theology rather than law was his natural destination, and it needed only the impulse of the remark of Buddens that the inevitable prospect before a true theologian is ignominy and trial to convert the student of law, who was profoundly exercised with religious conflicts, into a student of theology. Somewhat after the manner of the Wesleys at Oxford a little later, he studied the mystics, read the Bible, observed rigid devotional exercises, sought to quicken his sense of sin, avoided taking the Lord's Supper with unbelievers in the Lutheran Church, and took an active part in a religious union of students and in schools for poor children just outside Jena. He took his degree in 1726, and began to give free lectures on theology. In 1727 he made the acquaintance of the Moravian colony at Herrnhut and its head, Count Zinzendorf. A "collegium pastorale practicum" for the care of the sick and poor was in consequence founded by him at Jena, which the authorities at once broke up as a "Zinzendorfsian institution." But Spangenberg's relations with the Moravians were confirmed by several visits to the colony, and the accident of an unfavourable appeal to the lot alone prevented his appointment as chief elder of the community, March 1733. Meanwhile his free lectures in Jena met with much acceptance, and led to an invitation from Gotthelf Francke to the post of assistant professor of theology and superintendent of the educational depart-

ment of his orphanage at Halle. He accepted the invitation, and entered on his duties in September 1732. But it soon appeared that the differences between the Pietists of Halle and himself were far too serious to admit of any harmonious co-operation. He found their religious life too formal, legal, external, and worldly, and they could not sanction his comparative indifference to doctrinal correctness and his incurable tendency to separatism in church life. Spangenberg's participation in private observances of the Lord's Supper brought matters to a crisis. His intimate connexion with Count Zinzendorf was made a further charge against him. His preaching was pronounced "singular," and an "affected humility towards common people" obnoxious. He was offered by the senate of the theological faculty of Halle the alternative of doing penance before God, submitting to his superiors, and separating himself from Zinzendorf, or leaving the matter to the decision of the king, unless he preferred to "leave Halle quietly." The case came before the king, and on April 8, 1733, Spangenberg was conducted by the military outside the gates of Halle. At first he bent his steps to Jena, but Zinzendorf at once sought to secure him as a fellow-labourer, though, with that "jesuitry" of which Wesley subsequently complained, the count wished to obtain from him a declaration which would remove from the Pietists of Halle all blame with regard to the disruption. Spangenberg found amongst the Moravians his life work. He could amongst them carry out his fundamental principle that the churches are but spheres in all of which Christians are to be found, and that the one church of Christ is only where believers live in Christian fellowship. He joined the Moravians at a moment when the stability of the society was threatened, and a wise organizer, enterprising missionary, and theological teacher was imperatively required. He became its theologian, its apologist, its statesman and corrector, through sixty long years of incessant labour. For the first thirty years (1733–62) his work was mainly devoted to the superintendence and organization of the extensive missionary enterprises of the body in Germany, England, Denmark, Holland, Surinam, Georgia, and elsewhere. His missionary work tended to still further modify and broaden his theological opinions, unsatisfactory as the Pietists of Halle had found them in 1733. It was on an island off Savannah that Spangenberg startled John Wesley with his questions and profoundly influenced his entire future career. One special endeavour of Spangenberg in Pennsylvania was to bring over the scattered Schwenkfeldians to his faith. In 1741–42 he was in England collecting for his mission and obtaining the sanction of the archbishop of Canterbury. During the second half of this missionary period of his life he superintended as bishop the churches of Pennsylvania, defended the Moravian colonies against the Indians at the time of war between France and England, became the apologist of his body against the attacks of the Lutherans and the Pietists, and did much to moderate the mystical extravagances of Zinzendorf, with which his simple, practical, and healthy nature was out of sympathy. The second thirty years of his work (1762–92) were devoted to the consolidation of the German Moravian Church. Zinzendorf's death (1760) had left room and need for his labours at home. At Herrnhut there were conflicting tendencies, doctrinal and practical extravagances, and the organization of the brethren was very defective. Spangenberg proved himself to be the man required. In 1777 he was commissioned to draw up an *idea fidei fratrum*, or compendium of the Christian faith of the United Brethren, which was published two years afterwards and became the accepted declaration of the Moravian belief. As compared with

Zinzendorf's own writings, this book exhibits the finer balance and greater moderation of Spangenberg's nature, while those offensive descriptions of the relation of the sinner to Christ in which the Moravians at first indulged are almost absent from it. In his last years Spangenberg devoted special attention to the education of the young, in which the Moravians have since been so successful. He died at Berthelsdorf, September 18, 1792. In addition to the *Idea Fidei Mutuum*, Spangenberg wrote, besides other apologetic books, a *Declaration über die zither gegen uns angegangenen Beschuldigungen* (Leipzig, 1751), an *Apologetische Schlusschrift* (1752), *Leben des Grafen Zinzendorf* (1772-75), and his hymns are well known beyond the Moravian circle.

SPARROW (A S Sparrow, Icel *Spari*, Old High Germ *Sparo*), a word perhaps (like the equivalent Latin *Passer*) originally meaning almost any small bird, but gradually restricted in signification and nowadays in common English applied to only four kinds, which are further differentiated as Hedge Sparrow, House Sparrow, Tree Sparrow, and Reed-Sparrow—the last being a BUNTING (vol. ii. p. 525)—though when used without a prefix the second of these is usually intended.

1 The *House Sparrow*, called "Dunmoek" in many parts of Britain, the *Accentor modularis* of ornithologists, is the little brown breasted bird with an iron grey head and neck that is to be seen in nearly every garden throughout the country, unobtrusively and yet tamely seeking its food, which consists almost wholly of insects, as it progresses over the ground in short jumps, each movement being accompanied by a slight jerk or shuffle of the wings. Though on the Continent it regularly migrates, it is one of the few soft billed birds that reside throughout the year with us, and is one of the earliest breeders,—its well known greenish blue eggs, laid in a warmly built nest, being recognized by hundreds as among the surest signs of returning spring, but a second or even a third brood is produced later. The cock has a sweet but rather feeble song, and the species has long been accounted, though not with accuracy, to be the most common dupe of the Cuckoo. Several other species are assigned to the genus *Accentor*, but all, except the Japanese *A. rubinus*, which is the counterpart of the British Hedge Sparrow, inhabit more or less rocky situations, and one, *A. collaris* or *alpinus*, is a denizen of the higher mountain ranges of Europe, though it has several times strayed to England. The taxonomic position of the genus is regarded by some systematists as doubtful, but to the present writer there seems no good reason for removing it from the group which contains the Thrushes and Warblers (*Turdidae* and *Sylviidae*), to which it was long referred.

2 The *House Sparrow*, the *Fringilla domestica* of Linnæus and *Passer domesticus* of modern authors, is far too well known to need any description of its appearance or habits, being found, whether in country or town, more attached to human dwellings than any other wild bird, nay, more than that, one may safely assert that it is not known to thrive anywhere far away from the habitations or works of men, extending its range in such countries as Northern Scandinavia and many parts of the Russian empire as new settlements are formed and land brought under cultivation. Thus questions arise as to whether it should not be considered a parasite throughout the greater portion of the area it now occupies, and as to what may have been its native country. Moreover, of late years it has been inconsiderately introduced to several of the large towns of North America and to many of the British colonies, in nearly all of which, as had been foreseen by ornithologists, it has multiplied to excess and has become an intolerable nuisance, being unrestrained by the natural checks which partly restrict its increase in Europe and Asia. Whether indeed in the older seats of civilization the House Sparrow is not decidedly injurious to the agriculturist and horticulturist has long been a matter of discussion, and no definite result that a fair judge can accept has yet been reached. It is freely admitted that the damage done to growing crops is often enormous, but as yet the service frequently rendered by the destruction of insect pests cannot be calculated. Both friends and foes of the House Sparrow write as violent partisans,¹ and the truth will not be known until a series of experiments,

¹ The most recent attacks upon it are contained in the various issues of the *Report of Observations of Injurious Insects and Common Crop Pests*, annually made by Miss Eleanor Ormerod, and in a little volume bearing the title of *The House Sparrow*, published in 1885,

conducted by scientifically trained investigators, has been instituted, which, to the shame of numerous agricultural and horticultural societies, has not yet been done. It is quite likely that the result will be unfavourable to the House Sparrow, from what has been said above as to its being so dependant on man for its subsistence, but, while the evil it does is so apparent,—for instance, the damage to ripening grain crops,—the extent of the counterbalancing benefit is quite uncertain, and from the nature of the case is often overlooked. In the South of Europe the House Sparrow is in some measure replaced by two allied species, *P. hispaniolensis* and *P. italicus*, whose habits are essentially identical with its own, and it is doubtful whether the Sparrow of India, *P. indicus*, is specifically distinct, but Africa has several members of the genus which are decidedly so.

3 The *Tree Sparrow*, the *Fringilla montana* of Linnæus and *Passer montanus* of modern writers, in appearance much resembling the House Sparrow, but easily distinguishable by its reddish brown crown, the black patch on the sides of its neck, and its doubly barred wings,² is a much more local species, in England generally frequenting the rooks of pollard willows that line so many rivers and creeks, in the holes of which it breeds, but in some Eastern countries, and especially in China, it frequents houses, even in towns, and so fills the place of the House Sparrow. Its geographical distribution is extensive, and marked by some curious characters, among which may be mentioned that, being a great wanderer, it has effected settlements even in such remote islands as the Faroes and some of the Outer Hebrides.

That the genus *Passer* properly belongs to the *Fringillidae* is admitted by most ornithologists, yet there have been some who would refer it to the Weaver-birds, *Ploceidae*, if they are to be accounted as forming a distinct Family,—a matter which is not at all clear. The American birds called "Sparrows" have little in common with the members of the genus *Passer*, and probably belong rather to the family *Emberizidae* than to the *Fringillidae*. (A N)

SPARROWHAWK See HAWK

SPARTA, after Athens, was the most powerful and important of the Greek states. Her fame rested mainly on her soldiers, her military discipline, her somewhat narrow patriotism, and her intense political conservatism, in general intellectual culture, in art and in everything connected with it, she was immeasurably inferior to Athens, and even to some of the other Greek states, though there is evidence to show that a genius and a taste for sculpture and music were by no means wanting to her citizens. Her eminent men were almost all eminent as soldiers, and few of them had any pretensions to rank as able and enlightened statesmen. No such man as Themistocles or Pericles ever appeared in Sparta, she produced no great thinkers or philosophers, the typical Spartan, in short, was a brave and well-trained soldier, with a decided simplicity of character and strong religious scruples, amounting to what we must call superstition, which from time to time were a hindrance to prompt action and discredited the state in the public opinion of Greece.

Sparta was not so much a city as a cluster of open villages in a plain in the heart of Laconia (see vol. xi. plate I), in the middle valley of the Eurotas, on the west bank of the river, between the ranges of Taygetus and Parion, and built in part on the spurs of these mountains. Its situation was very picturesque "hollow, lovely Lacedæmon"³ is Homer's description. Taygetus on the west rises to its greatest height of nearly 8000 feet just above the city, with primeval forests on its lower slopes, in which Spartans hunted the stag and the wild boar. Sparta seems to have been about six miles in circuit, it was not, like most Greek cities, near the coast,—Gythium, and consisting chiefly of three essays by Mr J. H. Gurney, jun., Lieut. Col. O. Russell, and Prof. Cones, but the last has only reference to the behaviour of the bird in the United States of America, where, from the reason above assigned, its presence was expected by almost all well informed persons to be detrimental.

² A more important difference is that the two sexes have almost the same plumage, while in the House Sparrow they are unlike in this respect.

³ Lacedæmon was simply another name for Sparta, though sometimes it seems to stand for the surrounding district.

the chief port of Laconia, being 30 miles distant, nor was it built with anything like the compactness of an Athens or a Corinth. The houses for the most part stood in spacious gardens, an open air life being altogether to the Spartan taste, and well suited to the pleasant genial climate of the valley. The olive still grows to great perfection in the neighbourhood, and the silk is said to be of particularly fine quality. The mountain ranges round the city gave it a very strong defensive position, and for a long period Sparta was without walls or fortifications, trusting exclusively to the prowess of her citizens till she was seriously menaced by the victorious Macedonians in the 4th century B.C. The city was never a very splendid one, the houses were plain and simple and there seem to have been no public buildings of striking magnificence. There was the so-called Brazen House of Athene on a hill within a large enclosure, with plates of bronze which gave it its name, on which, among other mythological scenes, were represented the labours of Hercules and the exploits of the great twin brethren, Castor and Pollux, who were specially honoured at Sparta. There was the theatre, still to be traced in huge quadrangular blocks of stone, and there were porticos and colonnades, and the chapels and tombs of Spartan heroes, such as Lycurgus, Leonidas, Brasidas. Sparta delighted to honour her worthy citizens, and paid them divine honours after death. The site of the city has not been thoroughly investigated, but it is a question whether much remains worth bringing to light. What has hitherto been discovered is poor and disappointing. Sparta's greatness as a city, as Thucydides (i. 10) clearly implies, fell very far short of her political importance as a state.¹

Sparta's history, passing over her share in the prehistoric Trojan War under her king Menelaus, the brother of Agamemnon, begins with the legislation of Lycurgus in the 9th century B.C. It was this, as has been explained in the article LYCURGUS, which made Sparta what she was, a state whose aim it was rather to hold her own within the Peloponnesus than to launch out into doubtful enterprises far away from home. Sparta was not naturally aggressive or ambitious, she was not easily roused to action even in great emergencies. She was safe amid her mountains from the perils to which other Greek cities were exposed. It would seem that in early days Argos had been decidedly the first power in the Peloponnesus, Sparta being second to her by a long interval. The relative position of the two states was reversed soon after the time of Lycurgus. The spirit and vigour which his discipline infused no doubt enabled Sparta, after two severe wars in the 8th and 7th centuries, to accomplish at last the complete conquest of Messene, the south western portion of the Peloponnesus, and so to become the undisputed mistress of at least two-fifths of the whole peninsula. By the year 600 B.C. Sparta was quite in the first rank of Greek states, and it was generally felt that she had a right to take the lead in Greek politics. In the 6th century she put down the tyrants, the heads of the democratic and popular party, in several Greek cities, and drove, for a time at least, the reforming and innovating Clisthenes from Athens. Sparta was the steady foe of democracy and popular government. The Spartans were themselves a small landowning aristocracy, in the midst of a comparatively numerous population, consisting of so-called Perioeci (dwellers round about), the aboriginal inhabitants, in fact, of Laconia, and of Helots or serfs, taken to a great extent from the conquered Messenians.

¹ For topographical details we must refer the reader to the elaborate works of the German scholar Curtius on the Peloponnesus and works based on them. Mure's *Greece* and Leake's *Morea* should be consulted.

The government was highly centralized, it was wholly in the hands of the Spartans, the Perioeci having no share in it, though many of them may have themselves been landowners, or at any rate have held land under Spartan landlords, and been well-to-do and prosperous. The Helots were farm labourers bound to the soil, slaves in every sense of the word, anything like self-respect being studiously made impossible for them. Spartans could put down a popular rising or a slave insurrection with cold-blooded cruelty, and in a panic following on an earthquake of unusual violence in 464 there was a deliberately-planned massacre of a multitude of Helots for the safety of Sparta, carried out and executed by Spartans in person. A calculating selfishness was a marked trait in Spartan character. Sparta seems always to have put her own interests before those of Greece, though she claimed to be the leading and representative Greek state. She was cautious and even timid, though the courage of her individual citizens in war was unsurpassed. Every Spartan was a hero on the battlefield, and a Spartan army was long assumed to be invincible. Sparta was not much of a colonizing state, but she could point to the famous city of Tarentum in southern Italy as her offspring, and to Lyctus (*H.* ii. 647, *xii.* 611) in Crete, whence came warriors to the Trojan War. In 491, when Greece was threatened with invasion by Persia, we find Athens appealing to Sparta and urging a complaint against the Ægnetans as traitors to Greece for having given earth and water, the symbols of submission, to the emissaries of the great king. In 480 a Spartan admiral commanded the Greek fleet off Artemisium against Xerxes, and in the following year a Spartan general, Pausanias, commanded the united forces of Greece in the famous battle of Plataea. All this implies a distinct recognition of Sparta as the head of Greece. The Persian War over, Athens under Cimon and Pericles developed extraordinary energy and took Sparta's place. Sparta indeed seems to have retired upon her laurels, and it was not without reluctance and much urgent pressure that she embarked in the Peloponnesian War, which, after twenty-eight years of hard fighting, ended in the overthrow of the Athenian empire and the capture of Athens by Lysander in 405. Sparta contributed greatly to the final result by despatching an able officer, Gylippus, to the relief of Syracuse in 414, when the city was on the point of surrendering to the Athenian armament. It was the decisive success of Gylippus in Sicily which turned the scale against Athens. The crushing blow of Ægospotami in 405, which annihilated her fleet and left her defenceless, and the subsequent surrender of the city transferred the supremacy of Greece once more to Sparta, but not for much more than thirty years. Sparta's policy was ungenerous and short-sighted, it consisted in establishing little oligarchical factions under Spartan control in the Greek cities, and soon degenerated into a tyranny which became utterly odious. All Sparta's worst qualities came out during this period "autonomy," which had been her watchword throughout the war against Athens, became a dead letter under her rule, and the freedom of city life, so dear to a Greek, was crushed out under her officials and commissioners, whom she thrust on a number of Greek cities. Still more did she disgust all the better men of Greece by concluding, after a series of intrigues for her own selfish ends, a peace with Persia in 387, known as the peace of Antalcidas, the Spartan through whom it was negotiated. It was a dishonourable peace for Greece, as its effect was to facilitate Persian intervention in Greek affairs and make the king of Persia the arbiter of Greek disputes and differences. Meanwhile Athens was recovering herself, the tables were soon turned on Sparta, and her maritime

power collapsed before the united action of Athens and Persia. In the Peloponnesus Sparta was still supreme, but Thebes, she felt, might become a dangerous rival and must be humbled. She insisted that the townships of Boeotia must be "autonomous" and independent of Thebes, and so contrived to pick a quarrel with that state, which to Sparta's cost had at that time the famous Epaminondas, the greatest, perhaps, of Greek generals, among her leading citizens. In 371 came Sparta's crushing defeat at Leuctra, a blow from which she never really recovered, though her courage and military discipline long survived it. But her prestige was gone. Epaminondas carried the war into the heart of Laconia and penetrated to Sparta itself. His victory at Mantinea in 362 gave independence to Messene, and Sparta was now politically ignored by her old allies.

From this time Sparta almost drops out of Greek history. She took no part in the struggle against Macedon, no Spartan soldier stood by the side of the Athenians and Thebans at Chæronea. She seems to have sunk into political apathy, very possibly she may have had to concentrate all her remaining strength and energy in keeping down her Helots and the native population of Laconia. When Alexander was winning his victories in Asia, she intrigued feebly against Macedon, and she would take no part in the congress of the Greek states at Corinthus which declared Alexander "Leader of the Greeks."

She appears once again, but as not much more than the ghost of her former self, in the 3d century B.C., attempting vainly in 281 to unite Greece against the Macedonian Antigonos, and repulsing Pyrrhus from her walls in 272, Spartan women working at the city's defence, and a few Spartan warriors driving back the formidable soldier-king. There was still the old spirit about her, but the number of her citizens is said to have dwindled down to 700, and in her last days, with a wealthy few in the midst of a poor and needy people, Sparta had shrunk into the narrowest and feeblest of oligarchies. In the latter half of the 3d century B.C., in the days of the Achaean league, a vigorous but unsuccessful attempt at internal reforms and a restoration of the old discipline of Lysurgus was made by two of her kings, Cleomenes and Agis. She sank finally, we know not how, under the degrading dominion of a sort of robber chief, Nabis, who fastened his tyranny upon her by the support of emancipated slaves and mercenaries of the lowest class. Her best citizens were put to death or banished, and she was debased into a refuge of pirates and robbers. Nabis and his vile gang were put down by Philopœmon in the name of the Achaean league, and Philopœmon completed his work by razing the walls of Sparta and abolishing her old institutions. Rome simply looked on, knowing well that she was mistress of the situation, and let matters drag on till 146, when she captured Corinth, and closed the page of Greek history. (W J B)

SPARTACUS, the leader of a formidable insurrection of slaves against Rome in the 1st century B.C., was a Thracian by birth, and perhaps a descendant of the kings of Panticapœum whose name he bore. He served in the Roman army, but seems to have deserted, for we are told that he was taken prisoner and sold as a slave. Destined for the arena, he, with a band of his fellow-gladiators, broke out of a training school at Capua and took refuge on Mount Vesuvius (73 B.C.). Here he maintained himself as a captain of brigands, his lieutenants being Crixus and Oenomaus, who like himself had been gladiators. Their numbers soon swelled through the accession of runaway slaves and desperados from the neighbourhood. A hastily-collected force of 3000 men under Claudius endeavoured to besiege and starve out the rebels, but the latter clambered down the precipices and put the Romans to

flight. Swarms of hardy and desperate men now joined the rebels, and when the prætor Publius Varinius took the field against them he found them entrenched like a regular army on the plain. But they gave him the slip, and when he advanced to storm their lines he found them deserted. From Campania the rebels marched into Lucania, a country better suited for guerilla warfare. Here, in spite of the commands and enticements of Spartacus, the slaves committed excesses of lust and cruelty. Varinius followed him, but was defeated in several engagements and narrowly escaped being taken prisoner. Spartacus, whose heart was "where his rude cottage by the Danube lay," now endeavoured to push northward. His object was to cross the Alps and allow the slaves, who were mostly Thracians, Germans, and Gauls, to disperse to their homes. But intoxicated by success his wild followers refused to listen to him, their thoughts were all of plunder, and their track was marked by the devastation of Italy. Vols, Nuceria, Thurii, Metapontum, were sacked with every circumstance of savage cruelty. In this serious position of affairs the senate despatched both consuls against the rebels (72 B.C.). The German slaves under Crixus, who had separated from the rest, were defeated and cut in pieces at Mount Garganus in Apulia by the prætor Arrius. But Spartacus overthrew both consuls, one after the other, and then pressed towards the Alps. Cassius, governor of Cisalpine Gaul, and the prætor Manlius flung themselves in his way at the head of 20,000 men, but were trampled under foot. Freedom was within sight, but with fatal infatuation the slaves declined to abandon Italy. Spartacus led them against Rome, but their hearts seem to have failed them, for the capital was not attacked. Spartacus then occupied the port of Thurii and tried to procure supplies of iron and bronze, probably through the pirates. He also endeavoured by means of the herds of horses captured in southern Italy to form a body of cavalry. The conduct of the war against Spartacus, together with eight legions, was now committed to the prætor Marcus Crassus. He restored discipline by decimating the first troops that ran before the enemy. In the next battle Spartacus was worsted and retreated towards the straits of Messina, intending to cross into Sicily, where he would have been welcomed by fresh herds of slaves, but the pirates who had agreed to transport his army proved faithless. Crassus endeavoured to shut in the rebels by carrying a ditch and rampart right across the peninsula, a distance of 32 miles. But on a wintry night Spartacus forced the lines, and once more Italy lay at his feet. Disunion, however, was at work in the rebel camp. The Gauls and Germans had again drawn off from the main body. Crassus attacked and destroyed them. Spartacus was now fain to secure a retreat into the mountains of Petelia (near Strongoli in Calabria), and succeeded in inflicting a reverse on the pursuing army. But his men refused to retreat farther, and in a pitched battle which followed soon afterwards the rebel army was annihilated. Spartacus, who had stabbed his horse before the battle began, fell sword in hand. A body of the rebels which had escaped from the field was met and cut in pieces by Pompey, who, with his usual knack of reaping where other men had sowed, claimed and received the credit of having put an end to the war (71 B.C.). Six thousand slaves, who had not found a soldier's death, were crucified along the high road from Capua to Rome.

A history of the war against Spartacus has to be pieced together with much uncertainty from the vague, scrappy, and somewhat discrepant accounts of Plutarch (*Crassus*, 8-11), Appian (*Bell. Civ.*, I, 116-120), Florus (*ii* 8 [iii 20]), Livy (*Epit.*, xvi, xcvii), and Sallust (fragments of the *Historie*). Sallust's description seems to have been full and graphic, but unfortunately only a few fragments of it remain.

SPECIES In logic the term "species" is applied to any group of individuals agreeing in some common attribute or attributes, and included along with other groups in a higher category, that of "genus," which comprehends the fewer and more general attributes in which all agree and ignores those in which they differ. The application of these terms in logic is thus purely relative, any genus, however large, may be but a species of a still larger genus. But in arranging the innumerable objects of the natural sciences the naturalist finds it necessary to restrict the terms "species" and "genus" to the two lowest groupings, and to distinguish the higher aggregates by special terms, as "family," "order," "class," &c. Early writers had but a loose conception of many different "kinds" of animals and plants, and spoke only of species and genus in their purely logical relations, with varying breadth of content. The term "species" was limited to its natural history usage in the end of the 17th century by John Ray. His conception of "specific characters" rested, not only on close and constant resemblance in outward form, but also on the likeness of offspring to parent, a considerable measure of variability being, however, recognized. Amongst subsequent authors this conception of common descent or parentage became more and more prominent, while the progress of successful definition of species made the limits of their variability seem always narrower and of less importance, and in this way the useful working conception of the tolerable definiteness of species gradually crystallized into the absolute dogma of their fixity. Then Linnæus in his *Philosophia Botanica* gave the aphorism "species tot sunt diversæ, quot diversæ formæ ab initio sunt ereitæ" (we reckon just as many species as there were forms created at the beginning), which was generally accepted. Buffon's obstinate rejection of the Linnæan classification was associated with a belief in the modifiability of species, and showed some foresight of the doctrine elaborated soon afterwards by LAMARCK (q.v.). The general acceptance of this dogma was, however, effected by the influence of Cuvier, its overthrow dates only from the publication of Darwin's *Origin of Species* (1859), of which the argument need not be here repeated. (See EVOLUTION, MORPHOLOGY.) The genealogical conception of species was thus established more firmly than ever, though cleared from its former associations, in Haeckel's phrase, the species is the whole succession of organisms which exhibit the same form in the same environment. The rash generalization, that distinct species are to be recognized by their incapacity for the production of fertile hybrids, was next overthrown, while closer study has cleared away the notion of the equal definiteness of all specific forms. We now know that, while many forms, like the pearly nautilus or the Venus's fly-trap, do indeed exhibit the most perfect specific definiteness, the demarcation of equally definite species in other genera is rendered impossible by the existence of the most complete series of transitional forms, and the number of the species defined thus comes to depend simply on the personal equation of the systematist, on his predilection for "lumping" or "splitting," as the case may be. Thus, for example, the number of described German species of hawkweed (*Hieracium*) has ranged from 300 for one author, through 106 for another and 52 for a third, to less than 20 for a fourth. Similar instances of variable genera are afforded by the willows and the brambles, and many other common forms. This wide variability, as might be expected, seems to be more prevalent among the lowest forms of life, and the classical example of the relativity and variability of species has been furnished by Haeckel's beautiful monograph on the calcareous sponges (*Monographie der Kalkschwämme*, Jena, 1872), in which he offers twelve distinct arrangements of

the same set of forms from various points of view, among which the two most nearly conventional proposals respectively 21 genera and 111 species and 39 genera and 289 species. All such variable forms are in fact species in the making, which become definite in proportion as certain varieties become especially adapted to their environment, and become isolated by the dying out of the intermediate forms. With the limitations, however, the working usefulness of the morphological conception of species remains undiminished. The want of any absolute standard of specific difference is largely made up by practical experience and common sense, and the evolutionary systematists are less in danger than were their predecessors of either exaggerating or under-rating the importance of mere varieties. (See VARIATION.)

SPICHIC GRAVITY See HYDROMETER, vol. xii p. 536.

SPECTACLES are flat glass prisms, spherical or cylindrical lenses, employed to detect and correct defects of the eyes. They are made usually of crown glass or rock crystal ("pibbles"), the latter being somewhat lighter and cooler to wear. They are mounted in the well known rigid spectacle frame when for continuous use, — eye glasses being preferable where they are worn intermittently, and hand-glasses or lorgnettes where they are required to supplement temporarily the spectacles usually worn or where, as with extreme shortness of sight, no glass could be employed with comfort for any length of time.

Presbyopia—Presbyopia are used to conceal deformities or to protect the eyes in the many conditions where they cannot tolerate bright light, such as ulceration and inflammation of the cornea, certain diseases of the iris, ciliary body, choroid, and retina. They are made of bluish, "smoked," or almost black coloured glass, and are of very various shapes, according to the amount of obscuration necessary.

Prisms—Prisms are of great value in cases of double vision due to a slight tendency to squinting, caused by weakness or over action of the muscular apparatus of the eyeball. Prisms deflect rays of light towards their base. Hence, if a prism is placed in front of the eye with its base towards the nose, a ray of light falling upon it will be bent inwards, and seem to come from a point further out from the axis of vision. Conversely, if the base of the prism is turned towards the temple, the ray of light will seem to come from a point nearer the axis, and will induce the eye to turn inwards, to converge towards its fellow. In cases of myopia or short-sight owing to weakness of the internal recti muscles, the eyes in looking at a near object, instead of converging, tend to turn outwards, and so double vision results. If a suitable prism is placed in front of the eyes the double vision may be prevented. These prisms may be combined with concave lenses, which correct the myopia, or, since a concave lens may be considered as composed of two prisms united at their apices, the same effect may be obtained by making the distance between the centres of the concave lenses greater than that between the centres of the pupils. Again, to obviate the necessity for excessive convergence of the eyes so common in hypermetropia, the centre of the pupil should be placed outside the centre of the corrective convex lenses, these will then act as prisms with their bases inwards. Where, on the other hand, there is no tendency to squinting, care must be taken in selecting spectacles that the distances between the centres of the glasses and the centres of the pupils are quite equal, otherwise squinting, or at any rate great fatigue, of the eyes may be induced.

Spherical Lenses—Biconcave, biconvex, and concavo-convex (meniscus) lenses are employed in ophthalmic practice in the treatment of errors of refraction. Until recently these spherical lenses were numbered in terms of their focal

length, the inch being used as the unit. Owing principally to differences in the length of the inch in various countries, this method had great inconveniences, and is now giving place to a universal system, in which the unit is the refractive power of a lens whose focal length is one metre. This unit is called a "dioptric" (usually written "D"). A lens of twice its strength has a refractive power of 2 D, and a focal length of half a metre, and so on.

Concave lenses are used in the treatment of myopia or short-sight. In this condition the eye is elongated from before backwards, so that the retina lies behind the principal focus. All objects, therefore, which lie beyond a certain point (the conjugate focus of the dioptric system of the eye, the far point) are indistinctly seen, rays from them have not the necessary divergence to be focused in the retina, but may obtain it by the interposition of suitable concave lenses. Concave lenses should never be used for work within the far point, but they may be used in all cases to improve distant vision, and in very short-sighted persons to remove the far point so as to enable fine work such as sewing or reading to be done at a convenient distance. The weakest pair of concave lenses with which one can read clearly test types at a distance of 18 feet is the measure of the amount of myopia, and thus fully correcting glass may be worn in the slighter forms of short-sight. In higher degrees, where full correction might increase the myopia by inducing a strain of the accommodation, somewhat weaker glasses should be used for near work. In the highest degrees the complete correction may be employed, but lorgnettes are generally preferred, as they can be removed when the eyes become fatigued. It must be remembered that short-sight tends to increase during the early, especially the school, years of life, and that hygienic treatment, good light, good type, and avoidance of stooping are important for its prevention.

Convex Lenses—In hypermetropia the retina is in front of the principal focus of the eye. Hence in its condition of repose such an eye cannot distinctly see parallel rays from a distance and, still less, divergent rays from a near object. The defect may be overcome more or less completely by the use of the accommodation. In the slighter forms no inconvenience may result, but in higher degrees prolonged work is apt to give rise to aching and watering of the eyes, headache, inability to read or sew for any length of time, and even to double vision and internal strabismus. Such cases should be treated with convex lenses, which should be theoretically of such a strength as to fully correct the hypermetropia. Practically it is found that a certain amount of hypermetropia remains latent, owing to spasm of the accommodation, which relaxes only gradually. At first glasses may be given of such a strength as to relieve the troublesome symptoms, and the strength may be gradually increased till the total hypermetropia is corrected. Young adults with slighter forms of hypermetropia need glasses only for near work; elderly people should have one pair of weak glasses for distant and another stronger pair for near vision. These may be conveniently combined, as in Franklin glasses, where the upper half of the spectacle frame contains a weak lens, and the lower half, through which the eye looks when reading, a stronger one.

Anisometropia—It is difficult to lay down rules for the treatment of cases where the refraction of the two eyes is unequal. If only one eye is used, its anomaly should be alone corrected, where both are used and nearly of equal strength, correction of each often gives satisfactory results.

Presbyopia—Where distant vision remains unaltered, but, owing to gradual failure of the accommodative apparatus of the eye, clear vision within 8 inches becomes impossible, convex lenses should be used for reading of such

a strength as to enable the eye to see clearly about 8 inches distance. Presbyopia is arbitrarily said to commence at the age of forty, because it is then that the need of spectacles for reading is generally felt, but it appears later in myopia and earlier in hypermetropia. It advances with years, requiring from time to time spectacles of increasing strength.

Cylindrical Lenses—In astigmatism, owing to differences in the refractive power of the various meridians of the eye, great defect of sight, frequently accompanied by severe headache, occurs. This condition may be cured completely, or greatly improved, by the use of lenses whose surfaces are segments of cylinders. They may be used either alone or in combination with spherical lenses. The correction of astigmatism is in many cases a matter of considerable difficulty, but the results to vision almost always reward the trouble.

Convex spectacles were invented towards the end of the 13th century, perhaps by Roger Bacon. Concave glasses were introduced soon afterwards. Airy, the astronomer, about 1827, corrected his own astigmatism by means of a cylindrical lens. Periscope glasses were introduced by Dr W. H. Wollaston. (A. B. R.)

SPECTROSCOPY The spectroscope is an instrument which separates luminous vibrations of different wavelengths, as far as is necessary for the object in view. It consists of three parts,—the collimator, the prism or grating, and the telescope. The collimator carries the slit through which the light is admitted and a lens which converts the diverging pencil of light into a parallel pencil. The pencils carrying light of different wave lengths are turned through different angles by the prism or grating, which is therefore the essential portion of the spectroscope. The telescope serves only to give the necessary magnifying power, and is dispensed with in small direct vision spectroscopes. For a description of the different kinds of prism used, see OPTICS, and for an explanation of the action of the grating, see WAVE THEORY. The most important adjustment in the spectroscope is that of the collimator. Especially in instruments of large resolving power it is essential for good definition that the light should enter the prism or fall on the grating as a parallel pencil. For a method allowing an easy and accurate adjustment for each kind of ray, see an article in *Phil. Mag.*, vol. VII p. 95 (1879).

Prisms are nearly always used in the position of minimum deviation, but, if the collimator is properly adjusted, this is by no means a necessary condition for good definition. Prisms as generally cut, with an isosceles base, give the greatest resolving power in the position of minimum deviation, but the loss in resolving power is not great for a small displacement. The dispersion and magnifying power of a prism can be considerably altered by a change of its position, and a knowledge of this fact is of great value to an experienced observer. The use of a prism in a position different from that of minimum deviation is, however, a luxury which only those acquainted with the laws of optics can indulge in with safety.

Lord Rayleigh has given the theory of the spectroscope under OPTICS, and shown on what its resolving power depends. There is no connexion between resolving power and dispersion, any value of resolving power being consistent with any value of dispersion. To obtain large resolving power with small dispersion requires, however, the use of inconveniently large telescopes and prisms or gratings. It is easy, on the other hand, to obtain small resolving power together with large dispersion.

The following definitions would be found of general use if adopted. **Resolving Power**—The unit resolving power of a spectroscope in any part of the spectrum is that resolving power which allows the separation of two lines differing by the thousandth part of their own wave-length or wave-number,—the wave-number being the number

of waves in unit length. *Purity*—The unit purity of a spectrum is that purity which allows the separation of two lines differing by the thousandth part of their own wave-length or wave number. We speak of the resolving power of a spectroscope and of the purity of a spectrum. The resolving power is a constant for each spectroscope, and independent of the width of the slit. The purity of a spectrum, on the other hand, depends on the width of the slit, unless that width is small compared to a certain quantity presently to be mentioned. The resolving power of a spectroscope is numerically equal to the greatest purity of spectrum obtainable by it.

Adopting these definitions, we get from Lord Rayleigh's equations for the resolving power R of a grating

$$1000 R = mn,$$

where n is the total number of lines used on the grating and m the order of the spectrum. For a spectroscope with simple prisms we get

$$1000 R = - (t_2 - t_1) \frac{\partial \mu}{\partial \lambda},$$

where t_2 and t_1 are the greatest and smallest lengths of paths in the dispersive medium. If we put for the refractive index of the medium $\mu = A + B/\lambda^2$ we may write

$$1000 R = 2B(t_2 - t_1)/\lambda^3$$

It will be seen that, while the resolving power of a spectroscope with grating depends only on the order of the spectrum and is independent of the wave-length for each order, the resolving power of a spectroscope with prism will vary inversely as the third power of the wave-length λ , so that the resolving power will be about eight times as great in the violet as in the red (see OPTICS). If compound prisms are used we must write

$$1000 R = 2' B_2 t_2 - B_1 t_1 / \lambda^3,$$

where t_2 is the greatest effective length of path in one medium, t_1 in the other medium, B_2 and B_1 being the dispersive constants for the two media.

The purity P of a spectrum is given by the equation

$$P = \frac{\lambda}{d\psi} R,$$

where d denotes the width of slit and ψ is the angle subtended by the collimator lens at the slit. If the slit is sufficiently narrowed, $d\psi$ may be made small compared to λ , and in that case the purity of the spectrum is independent of the width of slit and equal to the resolving power. If, on the other hand, a wide slit is used, so that $d\psi$ is large compared to λ , the purity becomes inversely proportional to the width of slit. In actual work the slit is generally of such width that neither term in the denominator of the expression for purity can be neglected.

There is a necessary limit to the resolving power of all optical instruments, depending on the fact that light consists of a series of groups of waves incapable of interfering with each other. If it is true, as is generally believed, but without sufficient reason, that a retardation of 50,000 wave-lengths is sufficient to destroy the capability of interference—that is to say, that the groups consist on the average of approximately 50,000 waves—the maximum purity obtainable in any spectroscope is 50. The closest line resolved with a grating, as far as the present writer is aware, requires a resolving power of about 100. Professor Piazzi Smyth has with prisms realized a purity of 50. It would seem, therefore, that the theoretical limit of purity has very nearly been reached, for, though the estimate of 50,000 waves to the group is in all probability too small, there are other considerations which render it highly improbable that the total number of waves to the group should, for sunlight at any rate, be more than two or three times larger. The limit of possible purity will very likely depend on the temperature of the luminous body.

Almost the greatest practical difficulty which the spectroscopist has to contend with generally is the want of sufficient light. The following remarks apply to line spectra principally, but they hold also almost entirely for the spectra of fluted bands, which break up into lines under high resolving power. The maximum illumination for any line is obtained when the angular width of the slit is equal to the angle subtended by one wave-length at a distance equal to the collimator aperture. In that case $d\psi = \lambda$ and the purity is half the resolving power. Hence when light is a consideration we shall not, as a rule, realize more than half the resolving power of the spectroscope. If the visual impression depended only on the intensity of illumination, a further widening of the slit should not increase the visibility of a line. As a matter of fact spectroscopists generally work with slits wider than that which theoretically gives full illumination. The explanation of the fact is physiological, visibility depending on the apparent width of the object. If different spectroscopes have their slits of such width that the apparent width of a line as seen by the eye is the same, and if the magnifying power is such that the pupil is just filled with light, the purity of the spectrum is directly proportional to the resolving power. We come to the conclusion therefore, that for both narrow and wide slits the efficiency of a spectroscope depends exclusively on its resolving power. It has been pointed out by Lord Rayleigh that, owing to the want of definition in the optical images on the retina when the full aperture of the pupil is used, the pencil must be contracted to a third or a quarter of its natural width, if full resolving power is to be obtained. This is accompanied with a serious loss of light, which can be partly obviated by contracting the horizontal aperture only (the refracting edge being supposed vertical). There are two ways of doing this. One consists in the use of magnifying half prisms. But the loss of light by reflexion in simple half prisms more than counterbalances the advantage, compound half prisms like those used by Christie may, however, be employed. We may also use prisms of three or four times the height of the effective horizontal aperture, with correspondingly large telescopes, and then by the eye-piece contract the beam until its vertical section fills the pupil. The latter plan, though theoretically best, involves more expensive apparatus and prisms of very homogeneous material.

The question of illumination is important also when photography is used for spectroscopic analysis. For a given intensity of the source of light the intensity of the image on the sensitive film will be directly proportional to the solid angle of the cone of light forming the last image, and will be independent of the arrangement of intermediate lenses. Hence lenses with as short a focus compared to aperture as is consistent with good definition should be used in the camera.

The methods of recording and reducing spectroscopic observations are described in all books and treatises on the subject and may therefore be passed over here.

A lens is often used to concentrate the light of the source on the slit. There is some loss of light due to reflexion from the surface of the lens, but its position, aperture, and focal length do not affect the luminosity of the spectrum seen as long as the whole collimator is filled with light.

Bodies are rendered luminous for spectroscopic investigation either by being placed in the Bunsen flame or by the help of the electric current. A little difficulty may arise where the body is given in solution and does not show its characteristic lines in the flame. Lecoq de Boisbaudran takes the spark from the surface of the solution. The present writer has found the tube sketched in the figure on the next page a great improvement on those commonly used, if a sufficient quantity of the solution is at

hand, otherwise the method is too wasteful. The current is brought into the solution by a platinum wire, sealed into a small glass tube, the platinum wire reaches about to the level of the open end of the tube. A capillary of thick-walled glass tubing is placed over the platinum wire, the liquid rises in the capillary and sparks can be taken as from a solid. The lines due to the glass are easily eliminated. If a small quantity of material only is available, the plan adopted by Bunsen and extensively used by Hartley¹ seems the most successful. Pointed pieces of charcoal (Bunsen) or pieces of graphite pointed to a knife edge (Hartley) are impregnated with the liquid, and the spark is taken from them. Some substances, when introduced into a vacuum tube, especially near the negative pole, and under great exhaustion, show a characteristic phosphorescence. Becquerel was the first to examine the spectra shown under these circumstances, and Crookes has lately used the same method with great success.

Spectra of Metalloids

A good deal of discussion has taken place on the spectra of the metalloids, owing to the fact that they seem to be able to give different spectra under different circumstances. Spectra have occasionally been assigned to the elements which on further investigation were found to belong to some compound present. According to the general opinion of spectroscopists at present, different spectra of the same elements are always due to different allotropic conditions. If a complex molecule breaks up into simpler molecules the breaking up is always accompanied by a change of spectrum.

Nitrogen.—(a) The line spectrum appears whenever a strong spark (or discharge) is taken in nitrogen gas. It is always present when metallic spectra are examined by the ordinary method of allowing the jar discharge to pass between metallic poles.² Hartley (*Phil Trans*, 1884, part 1) has measured the ultra violet lines of the air spectrum, but has not separated the oxygen from the nitrogen lines. (b) The band spectrum of the positive discharge, which is generally called the band spectrum of nitrogen, always appears when the discharge is sufficiently reduced in intensity. The spectrum consists of two sets of bands of different appearance, one in the less refrangible part and one in the more refrangible part of the spectrum, the two sets of bands overlapping in the green. Hence some observers believe the spectrum to be made up of two distinct spectra. Philler and Hittorf (*Phil Trans*, 1865) gave a coloured drawing of this spectrum, which is one of the most beautiful that can be obtained. The most complete drawing of it is given by Piazzi Smyth (*Trans Roy Soc Edin*, vol xxv part iii), and there is also a good drawing by Hasselberg (*Vom Acad Imp de St Petersburg*, vol xxv). (c) The glow which surrounds the negative electrode in an exhausted tube shows in many cases a spectrum which, as a rule, is not seen in any other part of the tube. The memoir of Hasselberg contains a drawing of it. The spectrum seen when a weak spark is taken in a current of ammonia is neither that of nitrogen nor that of hydrogen, but must be due to a compound of these gases. When the pressure of the gas is reduced, a single band is seen having a wave length from 5686 to 5627 Åth metres (*Nature*, vi p 350). When a spark is taken from a liquid solution of ammonia a more complicated spectrum appears (Lecoq de Boisbaudran), and, if ammonia and hydrogen are burnt together either in air or oxygen, a complicated spectrum is obtained the chemical origin of which has not been satisfactorily explained. Drawings of it are given by Dübbers (*Pogg Ann*, cxvii p 518) and by Hofmann (*Pogg Ann*, cxlvii p 95). The absorption spectrum of the red fumes of nitrogen tetroxide has often been mapped, the most perfect drawing is given by Dr B. Hasselberg (*Vom Acad Imp de St Petersburg*, vol xxv). According to Moser (*Pogg Ann*, clx p 177), three bands close to the solar line C disappear when the vapour is heated. Recently Deslandes has obtained in vacuum tubes some ultra violet bands which seem to be due to a compound of nitrogen and oxygen (*C R*, chap 1 p 1256, 1885).

Oxygen.—(a) The elementary line spectrum of oxygen is that which appears at the highest temperature to which we can subject oxygen, that is, whenever the jar and air break are introduced into the electric circuit. It consists of a great number of lines, especially in the more refrangible part of the spectrum. (b) The compound

line spectrum of oxygen appears at lower temperatures than the first. It consists, according to Piazzi Smyth, of six triplets and a number of single lines. This spectrum corresponds to the band spectrum of nitrogen. (c) The continuous spectrum of oxygen appears at the lowest temperature at which oxygen is luminous. The wide part of a Plücker tube, for instance, filled with pure oxygen generally shines with a faint yellow light, which gives a continuous spectrum. Even at atmospheric pressure this spectrum can be obtained by putting the contact breaker of the induction coil out of adjustment, so that the spark is weakened. (d) The spectrum of the negative glow was first accurately described by Willner, and is always seen in the glow surrounding the negative electrode in oxygen. It consists of five bands, three in the red and two in the green. For further information respecting these spectra, see Sehnster (*Phil Trans*, clxx p 37, 1879) and Piazzi Smyth (*Trans Roy Soc Edin*, vol xxv part iii). According to Egerell, the A and B lines of the solar spectrum are due to absorption by oxygen in our atmosphere, and some recent observations of Janssen seem to support this view.

Carbon.—(a) The line spectrum appears when a very strong spark is sent through carbonic oxide or carbonic acid. The ultra violet lines observed by Hartley when sparks are taken from graphite electrodes also belong probably to this spectrum. (b) Considerable discussion has taken place as to the origin of the spectrum seen at the base of a candle or a gas flame. At first observations seemed to point to the fact that it was due to a hydrocarbon. It has been ascertained, however, that sparks taken in cyanogen gas, even when dried with all care, show the spectrum, and a flame of cyanogen and oxygen gives the same bands brilliantly. These facts have convinced the majority of observers that the spectrum is a true carbon spectrum. The best drawing is given by Piazzi Smyth, who ascribes the spectrum, however, to a hydrocarbon. The flame of cyanogen, which had already been examined by Faraday and Draper before the days of spectrum analysis, shows a series of bands in the red, reaching into the green. There is no doubt that they are due to a compound of nitrogen and oxygen. Another series of bands in the blue, violet, and ultra violet have been also proved by Laving and Dewar to be due to a compound of nitrogen and carbon. If the discharge is passed at low pressure through carbonic acid or carbonic oxide a spectrum is seen which seems to belong to carbonic oxide. A very beautiful and remarkable drawing of this spectrum, especially of its most brilliant band, has been published by Piazzi Smyth.

Very little need be said of the remaining metalloids, as we do not possess a sufficiently careful examination of their spectra. Chlorine, bromine, and iodine show bands by absorption. If a spark is passed through the gases line spectra appear. Sulphur volatilized in a vacuum tube may show either a line or a band spectrum under the influence of the electric discharge. The absorption through the vapour of sulphur is continuous at first on volatilization, but as the vapour is heated to 1000° the continuous spectrum gives way to a band spectrum. A spark through the vapour of phosphorus gives a line spectrum. We may obtain the spectra of fluorine, silicon, and boron by comparing the spectra given by sparks taken in atmospheres of fluoride of boron and fluoride of silicon.

Spectra of Metals and their Compounds

Nitrogen.—If sparks are taken through hydrogen, four well known lines appear in the visible region of the spectrum. The remarkable series of ultra violet lines photographed by Dr Huggins in the spectra of some stars which in their visible part show hydrogen chiefly has suggested the question whether the whole series is not due to that gas. This has now been proved to be the case by Cornu, who has recently examined the hydrogen spectrum with great care. In vacuum tubes filled with hydrogen a complicated spectrum often appears which is so persistent that nearly all observers have ascribed it to hydrogen (though Salet had given reasons against that conclusion). According to Cornu, the purer the gas the fiercer does this spectrum become, so that the above mentioned line spectrum seems to be the only true hydrogen spectrum. A flame of hydrogen in air or oxygen shows a number of lines in the ultra violet belonging apparently to an oxide of hydrogen (Laving and Dewar, Huggins). Aqueous vapour gives an absorption spectrum principally in the yellow.

Alkali Metals.—The metals of the alkali group are distinguished by the fact that their salts give the true metal spectra when rendered luminous in the Bunsen burner, that is to say, their salts are decomposed and the radiation of their metallic base is sufficiently powerful to be visible at the temperature of the flame. Their spectra are not so easily seen if sparks are taken from the liquid solution, but Lecoq de Boisbaudran has obtained fine spectra of sodium and potassium by taking the spark from a semi fluid band of the sulphates. The most complete description of the spectra of sodium and potassium seen when the metals are heated up in the voltaic arc is given by Laving and Dewar (*Proc. Roy Soc*, clxx p 378, 1879), who have also mapped their ultra violet lines (*Phil Trans*, 1883, pt. i). Abney has found a pair of infra red lines

¹ *Phil Trans*, clxxv p 19 (1884).

² We may refer once for all to Watts, *Index of Spectra*, for a list of wave lengths of the different spectra.

belonging to sodium, with wave-lengths 8187 and 8199 (*Proc. Roy. Soc.*, xxii p 443, 1851). Becquerel finds lines in the infra red at 11 420. The vapour of sodium and potassium heated up in a tube is coloured and shows a spectrum of fluted band, but in the case of sodium the yellow line is always present at the same time. It is probable that the band spectrum belongs to the vapour, containing two atoms in each molecule, and that at higher temperatures the molecules are split up, the single atoms showing the line spectra. Both potassium and sodium show an additional absorption line (5510 for Na and 5730 for K) at the temperature at which the fluted bands appear. According to a suggestion of Laveing and Devar, these lines may depend on the presence of hydrogen, which it is very difficult to exclude. These experimenters have also described interesting but complicated absorption phenomena depending on the simultaneous presence of two or more metals. Thus sodium and magnesium show a band in the green ($\lambda=5300$), which does not appear when sodium alone or magnesium alone is volatilized. Potassium and magnesium show similarly two lines in the red (*Proc. Roy. Soc.*, xxv p 350, 1876). If a spark is taken from potassium in an atmosphere of carbonic oxide a band appears (5700), depending probably on a combination between the potassium and the carbonic oxide. Lockyer has observed certain curious phenomena (*Proc. Roy. Soc.*, vol. xxii p 378) taking place at the temperature at which the band spectrum of sodium changes into the line spectrum, these phenomena deserve a fuller investigation. Lithium furnishes a good example of a change in the relative intensity of lines at different temperatures. At the temperature of the flame the red line is the most powerful, an orange line being also seen. When a spark is taken from a liquid solution the orange line is far the strongest and a blue line is seen, which in its turn rapidly gains in intensity as the temperature is raised. When the spark is taken from solutions of different strengths the more concentrated solution shows a change in relative intensity of lines in the direction in which an increase of temperature would act. Combination of the metals with transparent acids does not when in solution show any appreciable absorption in the visible part of the spectrum, but Soret has mapped their ultra violet absorption.

Metals of Alkaline Earths.—Calcium, strontium, and barium are distinguished by the fact that their volatile compounds give fine spectra in the Bunsen flame. The more stable salts, as the phosphates and silicates, give the reaction only feebly or not at all. When a salt like the chloride of barium is introduced into the flame the spectrum is seen to change gradually, the spectrum seen at first is different according as the chloride, bromide, or iodide is used, while the spectrum which finally establishes itself is the same for the different salts of the same metal. Mitscherlich, who was the first to investigate carefully these phenomena (*Pogg. Ann.*, cxxi p 456, 1854), ascribes the spectra seen at first to the compound placed in the flame, while gradually the oxide spectrum gets the upper hand. This explanation has always been accepted, and receives support from the fact that the bromide spectrum is strengthened by introducing bromine vapour into the flame, and the other compound spectra can be similarly strengthened by introducing suitable vapours. There is in observation, however, made by Professors Laveing and Dewar which in one case is not compatible with Mitscherlich's explanation. "A mixture of barium carbonate, aluminium filings and lamp-black heated in a porcelain tube gave two absorption lines in the green, corresponding in position to bright lines seen when sparks are taken from a solution of barium chloride at wave lengths 5242 and 5136, marked α and β by Lecoq de Boisbaudran." These two lines, or rather bands, are the brightest in the spectrum commonly ascribed to barium chloride. In addition to the compound spectra the brightest of the metallic lines seen at a low temperature appear in the flame. The metallic line in the violet with calcium, in the blue with strontium, and in the green with barium. Sparks taken from a solution of the metallic salts show the compound spectra well, and in addition more of the true metallic lines than the flame. The best drawings of the compound spectra are those given in Lecoq de Boisbaudran's *Atlas*, but measurements with higher resolving powers are much wanted. When the salts are introduced into the voltaic arc numerous metallic lines appear which have been mapped by Thalen, Laveing and Dewar have investigated those lines which can be recognized and have also mapped the ultra violet spectra. Captain Allen has mapped a pair of infra red lines belonging to calcium between 8590 and 8600, and, according to Becquerel, with the help of a phosphoric ant screen bands or lines appear of still lower refrangibility (8550 to 8559). Lockyer (*Phil. Trans.*, clviii p 25, 1874) and Clark p 595, 1874) has measured and mapped as many of these lines as well as of many of the other metals.

The Rare Earth Group.—Yttrium presents comparatively few optical phenomena, as far as it has hitherto been investigated. Two groups of lines were mapped by Thalen and five in the ultra violet by Hartley (*Solar Chem. Soc.*, June 1883). The spectrum of erbium is well known from its green triplet, but the spectrum of the metal seems very sensitive to a change of

conditions. Full details are given by Laveing and Dewar in *Proc. Roy. Soc.*, xxxii p 189. These authors have found that some of the bands seen occasionally, when magnesium wire is burned in air, are due to a compound of magnesium and hydrogen. The spectrum appears when sparks are taken from magnesium poles in an atmosphere containing hydrogen. For a description of the peculiarities of the flame, arc, and spark spectrum, the reader is referred to the original paper. The ultra-violet spectrum, which contains several repetitions of the green triplet, has also been mapped and measured by Hartley and Adener (*Phil. Trans.*, clxxv, 1874, pt. 1). The spectra of zinc and cadmium are obtained either by sparks from liquid solution or by the spark, with Leyden jar, from the metal poles. The ultra violet spectra show for both elements a remarkable series of triplets, the lines of the cadmium triplet being about three times as far apart as those of the zinc triplets. The least refrangible of the series is in the blue with wave-lengths 5085.1, 4799.1, 4677.0 for cadmium, and 4809.7, 4721.4, 4679.5 for zinc.

Lead Group.—The spectrum of lead is best obtained by taking the spark from the metallic poles. Care must be taken, however, to renew the surface frequently, otherwise the oxide spectrum will gradually make its appearance. The oxide itself shows its spectrum, according to Lecoq de Boisbaudran, in the Bunsen burner. The salts of thallium show the principal metal line at the temperature of the flame. The spark spectrum is more complicated. The ultra-violet spectra of both lead and thallium have been mapped.

Copper Group.—The spectra of the metals belonging to this group are easily obtained in the ordinary way. When copper chloride is introduced into the Bunsen flame a fine spectrum of bands is seen. It is the same spectrum which is found when common salt is thrown upon white hot coals. This reaction for copper chloride is very sensitive, but it has never been satisfactorily decided whether the presence of copper is really necessary for its production or whether the spectrum belongs to a peculiar condition of chlorine vapour. Silver when first volatilized gives a green vapour, which at a low temperature shows continuous absorption, but at a higher temperature a spectrum of fluted bands (Lockyer). Mercury shows its lines with great brilliancy if introduced and heated in a vacuum tube. Some of the lines widen easily, and at higher pressures a continuous spectrum completely covers the background. The copper salts in aqueous solution absorb principally the red end of the spectrum, the green salts also the violet end. The glass, coloured green with oxide of copper, transmits through sufficient thickness exclusively the yellow and green rays between D and E (H. W. Vogel).

Cerium Group.—Yttrium gives a good spark spectrum from the solution of the chloride, the salts show no absorption bands. Crookes has found, however, that a certain substance yields brilliant phosphorescent bands under the influence of the negative pole in a vacuum tube. These bands he has, after a lengthy investigation, put down to yttrium compounds, and explained the changes they undergo in different compounds and the sensitiveness of the reaction. Lecoq de Boisbaudran, who obtains the same spectrum by taking a spark (without Leyden jar) from solutions, making the solution the positive pole, has expressed an opinion that the bands are not due to yttrium but to two substances provisionally called by him Za and $Z\beta$. He has also under certain conditions seen a higher temperature spectrum, which he ascribes to $Z\gamma$, leaving it undecided whether $Z\gamma$ is a new substance or identical with Za (*Phil. Trans.*, 1883, p 891, and *C. R.*, cl. p 552, cl. p 153).—**Lanthanum** is easily recognized by a strong spark spectrum.—**Cerium**, like yttrium and lanthanum, has no peculiar absorption spectrum when in combination and solution, although the salts are strongly coloured yellow, its line spectrum has characteristic lines in the blue.—**Didymium** is characterized spectroscopically by the fine absorption spectra of its salts. Different salts show slightly different spectra, but they can be recognized at first sight as didymium spectra. The crystals of didymium salts show remarkable differences in the absorption spectra according to the direction in which the ray traverses the crystal. Light reflected from the powdered salts shows the characteristic spectrum. According to Auer von Welsbach (*Monatsh. f. Chem.*, vi. p 477), didymium has lived up to its name διδυμια, "twins," for by fractional crystallization he has found it to be an intimate mixture of two substances, each of them giving half the absorption spectrum and half the emission spectrum of didymium.—**Terbium** has a characteristic line spectrum when the spark is taken from a solution of the salts.—The salts of **erbium** give a characteristic absorption spectrum, but till recently the drawings of it contained also absorption bands due to thulium and holmium. The spectrum of erbium, as previously mapped by Thalen, belongs almost exclusively to ytterbium, but he has recently mapped the lines belonging to what is now known as erbium (*C. R.*, xci p 326). Erbium salts heated in the Bunsen burner show a spectrum of bright bands without apparent volatilization.—**Ytterbium**, discovered by Marignac (atomic weight 173, Nilson), gives an absorption band in the ultra violet. Its luminous spectrum is rich in lines (Thalen, *C. R.*, xci. p 326).—**Samarium**, also discovered by

Marignac and called by him originally $\lambda\beta$, gives absorption bands in the visible part and in the ultra violet (Soret, *C R*, xc p 212). It frequently occurs with didymium, and most of the maps of the didymium spectrum contain the samarium bands. When precipitated with another metal it shows a brilliant phosphorescent spectrum (Crookes), which, however, is slightly different according to the metal. The peculiar yttrium spectrum is very weak even when it is mixed in considerable quantities with samarium but when the quantity of yttrium is increased to about 60 per cent a very rapid change takes place, and afterwards it is the samarium spectrum which is very weak. A band in the orange peculiar to the mixture, weak in pure samarium and absent in yttrium, is strongest in a mixture containing about 80 per cent. of samarium and 20 per cent. of yttrium. — *Holmium*, identified as a separate element by Soret (*C R*, xci p 375), has absorption bands in the visible part of the spectrum (6105, 5361, 4855 on Lecoq's map of chloride of erbium), and also a strongly marked ultra violet absorption spectrum — *Thulium*, likewise first recognized by Soret, is band 6510 on Lecoq's drawing of chloride of erbium, and also possesses a band at 6615. Thakén has measured the bright line spectrum (*C R*, xci p 176, 1880) — *Scandium* is characterized by a bright line spectrum (Thakén, *C R*, xci p 48, 1880) — *Gadolinium* (Marignac & Ya) has a weak absorption spectrum in the ultra violet and a characteristic phosphorescent spectrum (*Proc Roy Soc*, January 1886), but the latest researches of Crookes have rendered it probable that it is a mixture of several new elements (*Proc Roy Soc*, 10th Jan 1886) — The mosandrium of Lawrence Smith seems a mixture of gadolinium and erbium. The philippium of De la Fontaine was a mixture of yttrium and erbium, and the latest decupium of the same element is probably holmium.

Aluminium Group — The spectra of the metals belonging to this group can be obtained in the ordinary way by means of the electric spark. The chloride of indium shows the two strongest metallic lines, one in the indigo and one in the violet, when introduced into the Bunsen flame. According to Claydon and Hyscock, a number of other lines appear when the spark is taken from the metal electrodes. When a weak spark is taken from aluminium electrodes in air a band spectrum is often seen belonging apparently to the oxide, for it disappears when the spark is taken in hydrogen. Gallium, another metal belonging to this group, was first discovered by means of its spectroscopic reaction. The chloride shows two violet lines feebly in the Bunsen flame, but strongly if a spark is taken from the liquid solution. The ultra violet lines of indium and of aluminium have been photographed by Hartley and Adeney, as well as by LIVING and DEWAR. Some of the lines had been previously mapped by Cornu, whose researches extend furthest into the ultra violet. According to Stokes, aluminium shows lines more refrangible than those of any other metal, and the wave lengths of their lines as measured by Cornu are for one double line 1934, 1929, and for another 1860, 1842.

Metals of the Iron Group — The spectroscopic phenomena of this group are somewhat complicated. The line spectra can be obtained either by taking sparks from the metal or from the solution of a salt, and also by placing the metal in the voltaic arc. The lines are very numerous and very liable to alter in relative intensity under different circumstances. The great difference shown, for instance, between the arc and spark spectra of iron in the ultra violet region is shown in the map by LIVING and DEWAR in *Phil Trans*, 1885, pt 1. The visible part has also been investigated by the same authors and by LOCKYER, and much information has thus been added to the knowledge previously obtained by Kirchhoff, Angström, and Thakén. That part of the iron spectrum lying between wave length of 4071 and 2917 has been mapped by Cornu, LIVING and DEWAR's observations refer chiefly to the more refrangible region. Considering the very important part which the iron spectrum plays in solar observations, a full investigation of its changes by a variation of temperature would at the present time be of great value. If observations with the method adopted by Lecoq de Boisbrun were repeated with higher resolving powers they would add much to our knowledge. Some of the manganese salts, such as the chloride or carbonate, seem to be the only salts belonging to this group which show a characteristic spectrum when heated in the Bunsen burner or the oxyhydrogen flame. The spectrum observed in these cases is, according to Watts, the characteristic spectrum of the Bessemer flame, which disappears at the right moment for stopping the blast, it is probably due to an oxide of manganese. When a spark spectrum is taken from a solution of the chloride the same spectrum is seen, but the relative intensity of the lines depends on the length and the strength of the spark. The green coloured manganates show a continuous absorption at the two ends of the spectrum, transmitting in concentrated solutions almost exclusively the green part of the spectrum. The absorption bands of permanganate of potassium are well known and seem to be due to the permanganic acid, as they appear also with other permanganates. The green salts of nickel show a continuous absorption at the two ends of the spectrum. The cobalt salts show well defined absorption bands. Their careful

investigation by Dr W J Russell deserves special notice (*Proc Roy Soc*, xcvi p 268, 1881).

Metals of Chromium Group — The metallic spectra of this group have been measured principally by Thakén in the usual way. Lockyer and Roberts have obtained a channelled spectrum of chromium by absorption. As regards the spectra of compounds of chromium, the absorption of the vapour of chrome chromic anhydride has been measured by Emerson and Reynolds (*Phil Mag*, xlii p 11, 1871), and consists of a series of regularly distributed bands. The chromium salts all possess a decided colour and show interesting absorption phenomena. The chromates absorb the violet and blue completely, also the extreme red, and transmit only the orange, yellow, and in dilute solutions part of the green. The most complete investigation of the salts in which chromium plays the part of a base is due to Fehrd in a dissertation published at Freiburg. Potassium chrom alum, ammonium chrom alum, sulphate of chromium, when in solution, give an identical absorption for the same amount of chromium. The extreme red is freely transmitted by the violet solution, but the absorption grows rapidly towards the yellow. An indistinct absorption band ($\lambda=6790$ to $\lambda=6710$) is seen when the layer is thick or the solution concentrated. The strongest absorption takes place for a wave length of 5800. The green is transmitted again more freely, the minimum absorption taking place for a wave length 4880, the absorption then grows rapidly towards the violet. When the solutions are heated the colour changes to green, the absorption is increased throughout the spectrum, except in the green, where it remains nearly unchanged, and the minimum of absorption shifts to a wave length of 5090. The solution, which remains green on cooling, has, when compared with its original state, an increased absorption in the red and blue and a slightly diminished absorption in the green. When light is sent through plates cut out of crystals of potassium chrom alum or ammonium chrom alum, three absorption bands (6860, 6700, 6620) are seen in the red. The green and blue show the same absorption as the solution. The chloride in solution gives the same absorption as the chrom alums, — transmitting, however, slightly more light for the same quantity of chromium. The hot solution also shows the same changes, but with this difference that colour and absorption phenomena are almost entirely recovered on cooling. The nitrate (solution of chrome hydrochloric in nitric acid) agrees with chrom alum, but transmits more light. Red crystals of potassium chrome oxalate only transmit the red with an absorption band slightly less refrangible than B ($\lambda=6867$). The blue salt has the absorption band at a wave length of 7010 and transmits part of the light in the green and blue. The solutions of the salts show the same absorption as the crystals, with the position of the absorption band apparently unchanged. The warm solutions absorb more than the cold ones. The oxalate of chromium gives an absorption band of 6910 to 6800 and transmits the green and blue more freely than the double salt. The tartrate only shows the absorption band in the red very weakly and absorbs more red than the previously mentioned solutions. The acetate transmits more yellow than the other salts and has some broad absorption bands near a wave length of 7170. When the solution is heated it becomes green, absorbing the red more than when cold, but leaving the green and blue absorption unchanged. The absorption phenomena shown by uranium salts are more complicated than those of the chromium salts, but they are at the same time more characteristic, as the spectra are more definitely broken up into bands. According to Vogel, the uranic and uranous salts behave differently (*Praktische Spectral Analyse*, p 217), but a more careful investigation is desirable. Sorby finds that a mixture of zirconium and uranium dissolved in a hot acid shows characteristic bands, which are visible neither with uranium nor with zirconium alone.

There is little to be said as regards the remaining groups of metals (tin, antimony, gold). Their spectra are best obtained by taking the spark from metallic electrodes or by volatilization in the voltaic arc.

Influence of Temperature and Pressure on Spectra of Gases

If the spectrum of an element is examined under different conditions of temperature or pressure, it is often found to differ considerably. The change may be small — that is to say, the lines or bands may only show a different distribution of relative intensity — or it may be so large that no relationship at all can be discovered between the spectra. It has been pointed out by Kirchhoff that a change in the thickness of the luminous layer may produce a change in the appearance of the spectrum, and Zollner and Willner have endeavoured to explain in this way a number of important variations of spectra. But their explanation does not stand the test of close examination. The thickness of layer cannot be neglected in the discussion of solar and stellar spectra, or in the comparison of absorption spectra of liquids, but none of the phenomena which we shall notice here are affected by it.

Widening of Lines — The lines of a spectrum are found to widen under certain conditions, and, although probably all spectra are subject to this change, some are much more affected by it than

others. The lines of hydrogen and sodium, for instance, widen so easily that it is sometimes difficult to obtain them quite sharp. When a system of lines widens it is generally found that the most refrangible lines widen most easily. A line may expand equally towards both sides or chiefly towards one side, in the latter case the expansion towards the less refrangible side preponderates pretty nearly in every case. It is the almost unanimous opinion of spectroscopists that the widening is produced by an increase of pressure. If sparks are passed through gases, the lines are always broader at high than at low pressures, and the metallic lines are also broader when a spark is taken from them at higher pressures. Without altering the pressure, we may often produce a widening of lines by an increase in the intensity of the discharge, but here the pressure is indirectly increased by the rise of temperature. According to the molecular theory of gases, the following explanation might be given for the widening of lines. As long as a molecule vibrates by itself uninfluenced by any other molecule, its vibrations will take place in regular periods. The lines of its spectrum will consequently be sharp. But, if the molecule is placed in proximity with others, its vibrations will be disturbed by occasional encounters. During each encounter forces may be supposed to act between the molecules, and these forces will affect the regularity of the vibration. The question arises, whether for a given temperature and pressure a line may be of different width according as the molecule is placed in an atmosphere of similar or dissimilar molecules. Such a difference exists in all probability. If gases are mixed in different proportions, the lines are sharper when an element is present in small quantities, although the total pressure may be the same. There is one cause which limits the sharpness of spectroscopic lines: the molecules of a gas have a transitory motion. Those molecules which are moving towards us will send us light which is slightly more refrangible than those which move away from us, hence each line ought to appear as a band. In reality this width of lines generally is greater than that due to this cause.

Spectra of Different Orders—Spectra may be classified according to their general appearance. The different classes have been called orders by Plücker and Hittorf. At the highest temperature we always obtain spectra of lines which need no further description. At a lower temperature we often get spectra of channelled spaces or fluted bands. When seen in spectroscopes of small resolving power these seem made of bands which have a sharp boundary on one side and gradually fade away on the other. With the help of more perfect instruments it is found that each band is made up of a number of lines which lie closer and closer together as the sharp edge is approached. Occasionally the bands do not present a sharp edge at all, but are made up of a number of lines of equal intensity at nearly equal distances from each other. Continuous spectra, which need not necessarily extend through the whole range of the spectrum, form a third order, and appear generally at a lower temperature than either band or line spectrum. One and the same element may at different temperatures possess spectra of different orders. A discussion has naturally arisen as to the cause of these remarkable changes of spectra, and it is generally believed that they are due to differences of molecular structure. Thus sulphur vapour when volatilized shows by absorption a continuous spectrum until its temperature is raised to 1000°, when the continuous spectrum gives way to a spectrum of bands. We know that the molecule of sulphur is decomposed as the temperature is raised, and we are thus justified in saying that the band spectrum belongs to the molecule containing two atoms, while the continuous spectrum belongs to the more complex molecule which first appears on volatilization. When a strong electric spark is passed through the vapour of sulphur a bright line spectrum is seen, and this is believed to be due to a further splitting up of the molecule into single atoms.

Long and Short Lines—If the spectrum of a metal is taken by passing the spark between two poles in air the pressure of which is made to vary, the relative intensity of some of the lines is often seen to change. Similar variations take place if the intensity of the discharge is altered, as, for instance, by interposing or taking out a Leyden jar. It is a matter of importance to be able to use a method which in the great majority of cases will give at once a fair indication how each line will behave under different circumstances. This method we now proceed to describe. It has often been remarked, even by the earliest observers, that the metallic lines when seen in a spectroscope do not always stretch across the field of view, but are sometimes confined to the neighbourhood of the metallic poles. Some observations which Lockyer made jointly with Prof. von Fraunhofer led him to conclude that the distance which each metallic line stretched away from the pole could give some clue to the behaviour of that line in the sun. In 1872 Lockyer worked out his plan. An image of the spark was formed on the slit of the spectroscope, so that the spectrum of each line of the spark could be examined. Some of the metallic lines were then seen to be confined altogether to the neighbourhood of the pole, while others stretched nearly across the whole field. The relative length of all the lines was estimated. Tables

and maps are added to this memoir.¹ The longest lines (that is, those which stretch away farthest from the pole) are by no means always the strongest, and there are many instances where a faint line is seen to stretch nearly across the whole field of view, while a strong line may be confined to the neighbourhood of the pole, or is reduced sometimes to a brilliant point only. We give a few conspicuous examples of lines which are long and weak or short and strong. In lithium the blue line (4602.7) is brilliant but short. In lead 4062.5, one of the longest lines, is faint and according to Lockyer difficult to observe. In tin 5630.0 is the longest line, but it is faint, while the stronger lines near it (5588.5 and 5562.5) are shorter. The zinc lines 4923.8, 4911.2, 4809.7, 4721.4, 4679.5 are given by Thalén as of equal intensity, but the three most refrangible ones are longer. On reduction of pressure Lockyer found that some of the shorter lines rapidly decreased in length, while the longer lines remained visible and were some times hardly affected. When the spark was taken from a metallic salt instead of from the metal the short lines could not be seen, but only the long lines remained. An alloy behaves in the same manner as a compound, and by gradually reducing one constituent of an alloy we may gradually reduce the number of lines, which disappear in the inverse order of their length. Subsequent work has shown that the longest lines are also generally those which are most persistent on reduction of temperature, so that in the voltaic arc the longest lines seen in the spark are absent. In order to explain these facts it seems necessary in the first place to assume that the short lines are lines coming out at a high temperature only, but this explanation is not sufficient. Why should a mixture of different elements only show the longest lines of that constituent which is present in small quantities? In the case of chemical combinations we might assume that, the spark having to do the work of decomposition, the temperature of the metal is lowered, and that therefore the short lines are absent. But this cannot be if a chemical compound is replaced by a mechanical mixture. All these facts would be explained, however, if we assume that the spectrum of a molecule that is excited by molecules of another kind consists of those lines chiefly which a molecule of the same kind is already capable of bringing out at a lower temperature. It would follow from this that the effects of dilution are the same as those of a reduction of temperature,—which is the case.

Other Changes in Relative Intensity of Lines—Besides the changes we have noticed, there are others which have not been brought under any rule as yet. Lines appear sometimes at a low temperature which behave differently from the proper low temperature lines. These require further investigation. They may, in some cases at least, be due to some compound of the metal with other elements present. We give some examples. If a spark is taken from lead without the condenser the line 5005 appears, and Huggins has found it to be sensibly coincident with the chief line of the nebula. It is given as a strong line by Lecoq de Boisbaudran, who used feeble sparks, and in many cases it seems to behave as a low temperature line, it ought to be a long line therefore, but it is in reality short. In line 6100 of tin, Salet noticed that when a hydrogen flame contains a compound of tin an orange line appears, which is apparently coincident with the orange line of lithium. This line does not figure on any of the maps of the tin spectrum. Lockyer found that zinc, volatilized in an iron tube, showed by absorption a green line. It is very likely the line 5184 seen by Lecoq de Boisbaudran in sparks taken from solution of zinc salts. In the absorption spectra of sodium and potassium lines appear in the green which were shown by Lavey and Dewar not to be coincident with any known line of these metals. It was suggested by them that they are due to hydrogen compounds. The wave length of the sodium line is 5510 and that of the potassium line 7780. Lecoq de Boisbaudran mentions that an increase of temperature is often accompanied by a relatively greater increase in the brilliancy of the more refrangible rays. It is often said that such an increase is a direct consequence of the formula established by Kirchhoff. If the absorbing power of a molecule remains the same while the temperature is increased, it follows that the blue rays gain more quickly in intensity than the red ones, but the less refrangible rays ought never to decrease in intensity, the quantity of luminous matter remaining the same. Now such a decrease is actually observed in many cases when there is no reason to suppose that the quantity of luminous matter has been reduced. We must conclude, therefore, that the observed differences in the spectra are not solely regulated by Kirchhoff's law, but it is a perfectly plausible hypothesis that a higher temperature is in general accompanied by a decrease in the absorbing power of the less refrangible rays. As a stronger impact often brings out higher tones, stronger molecular shocks may bring out waves of smaller length. There are several instances of a regular increase in the relative intensity of the blue rays which may be ascribed to this cause. The most remarkable instance is perhaps seen in the spec-

¹ Phil. Trans., clxiii p. 253 (1873).

trum of phosphoretted hydrogen. If a little phosphorus is introduced into an apparatus generating hydrogen, the flame will show a series of bands chiefly in the green. The spectrum gets more brilliant if the flame is cooled. This can be done, according to Salet,¹ by pressing the flame against a surface kept cool by means of a stream of water or by surrounding the tube, at the orifice of which the gas is lighted, by a wider tube through which cold air is blown. The process of cooling the flame, according to Lecoq,² changes the relative intensity of the bands in a perfectly regular manner. The almost invisible least refrangible band becomes strong, and the second band, which was weaker than the fourth, now becomes stronger. Another example of a similar change is the spectrum shown by a Bunsen burner. By charging the burner with an indifferent gas³ (N, HCl, CO) the flame takes a greenish colour, and, though the spectrum is not altered, the least refrangible of the bands are increased in intensity. While in these instances the changes are perfectly regular, the more refrangible rays gaining in relative intensity as the temperature is increased, there are other cases, some of which have already been mentioned, in which the changes are very irregular, such as those which take place in the spectra of tin, lithium, and magnesium. In the case of zinc the less refrangible of the group of blue rays gains in relative intensity. We cannot, therefore, formulate any general law.

Numerical Relations between the Wave lengths of Lines belonging to the Spectrum of a Body

It seems *a priori* probable that there is a numerical relation between the different periods of the same vibrating system. In certain sounding systems, as an organ-pipe or a stretched string, the relation is a simple one, these periods being a submultiple of one which is called the fundamental period. The harmony of a compound sound depends on the fact that the different times of vibration are in the ratio of small integer numbers, and hence two vibrations are said to be in harmonic relation when their periods are in the ratio of integers. We may with advantage extend the expression "harmonic relation" to the case of light, although the so called harmony of colours has nothing to do with such connexions. We shall therefore define an "harmonic relation" between different lines of a spectrum to be a relation such that the wave lengths or wave numbers are in the ratio of integers, the integers being sufficiently small to suggest a real connexion. Some writers use the word in a wider sense and call a group of lines harmonics when they show a certain regularity in their disposition, giving evidence of some law, that law not being in general the harmonic law. We shall here use the expression in its stricter sense only. We begin by discussing the question whether there are any well ascertained cases of harmonic relationship between the different vibrations of the same molecule. The most important set of lines exhibiting such a relationship are three of the hydrogen lines which, when properly corrected for atmospheric refraction, are, as pointed out by Johnstone Stoney, very accurately in the ratio of 20 : 27 : 32 (*Phil Mag*, vol. p. 291, 1871). Other elements also show such ratios, but when a spectrum has many lines pure accident will cause several to exhibit spurious or numerical relations we may wish to impose on them. If we calculate the number of harmonic ratios which, within an assumed limit of accuracy, we may expect in a spectrum like that of iron, we find that there are in reality fewer than we should have if they were distributed quite at random (*Proc Roy Soc*, vol. p. 337, 1881). With fractions having a denominator smaller than seventy the excess of the calculated over the observed values is very marked, while there are rather more coincidences than we should expect on the theory of probability if we take fractions having a denominator between seventy and a hundred. The cause of this, probably, is to be sought in the fact that the lines of an element are liable to form groups and are not spread over the whole spectrum, as they would be if they were distributed at random. This increases the probability of coincidence with fractions between high numbers, and diminishes the probability of coincidence with fractions between low numbers. There is one point which deserves renewed investigation. When the limits of agreement between which a coincidence is assumed to exist are taken narrower, there is an increased number of observed as compared with calculated coincidences in the iron spectrum, and this would seem to point to the existence of some true harmonic ratios. With the solar maps and gratings put at our disposal by Professor Rowland, we may hope to obtain more accurate measurements, and therefore more definite information. Even if the wave lengths of two lines are found to be occasionally in the ratio of small integer numbers, it does not follow that the vibrations of molecules are regulated by the same laws as those of an organ pipe or of a stretched string. E. J. Balmer⁴ has indeed lately suggested a law which differs in an important manner from the laws of vibration of the organ

pipe and which still leaves the ratios of the periods of vibration integer numbers. According to him, the hydrogen spectrum can be represented by the equation

$$\frac{m^2}{m^2 - 4} \lambda_0 = \lambda,$$

where λ_0 is some wave length and m an integer number greater than 2. The following table (I) shows the agreement between the calculated and observed hydrogen lines. And the agreement is a very remarkable one, for the whole of the hydrogen spectrum is represented by giving to m successive integer values up to sixteen.

$\lambda_0 = 3645$			$\lambda_0 = 3645$		
m	$m^2 \lambda_0 / (m^2 - 4)$	Observed H ₂ Hydrogen Spectrum	m	$m^2 \lambda_0 / (m^2 - 4)$	Observed H ₂ Hydrogen Spectrum
3	6561.0	6562.1	10	3706.0	3705.0
4	4860.0	4860.7	11	3709.0	3707.5
5	4330.3	4340.1	12	3740.1	3745.5
6	4100.8	4101.2	13	3733.3	3730.0
7	3969.0	3968.1	14	3720.0	3717.5
8	3888.0	3887.5	15	3711.0	3707.5
9	3834.3	3834.0	16	3702.0	3699.0

The differences between the observed and the calculated numbers show a regular increase towards the ultra violet. It might be thought that a better agreement could be obtained by taking a number slightly different from four in the denominator, but this is not the case. On the contrary, the agreement in the visible part is at once destroyed if we make the ultra violet lines fit better. The agreement is not improved but rendered slightly worse if we take account of atmospheric refraction.

As a first approximation Balmer's expression gives a very good account of the hydrogen spectrum. If the law was general we should find that in the iron spectrum, for instance, which is the only spectrum carefully examined, those fractions would occur more frequently than others which can be put into the form $m^2/(m^2 - n^2)$, that is to say, $\frac{1}{2}$ and $\frac{3}{5}$ for fractions made up of numbers smaller than 10. A reference to the table in *Proc Roy Soc*, vol. p. 337, shows that these fractions do not occur more frequently than others. But, if we change the sign of n^2 in the denominator, we find $\frac{1}{2}$ and $\frac{3}{5}$ as the only fractions falling within the range of spectrum examined, and these two fractions are indeed those which occur more frequently than any others made up of numbers smaller than 10.

It might be worth trying to see whether the wave lengths of lines making up a fluted band can be put into the form $\frac{m^2}{m^2 \pm n^2} \lambda_0$, according to the sign chosen in the denominator, the band would shade off towards the blue or red. The form of expression seems at first sight well adapted, for it shows how by giving m gradually increasing numbers the lines come closer and closer together towards what appears in the spectrum as the sharp edge of the band. If we take periods of vibration instead of wave lengths Balmer's expression would reduce to

$$T = T_0 \left[1 - \left(\frac{n}{m} \right)^2 \right],$$

where T_0 is a fixed period of vibration, n a constant integer, and m an integer to which successive values are given from n upwards.

It is often observed, and has already been mentioned, that the spectrum of some elements contains in close proximity two or three lines forming a characteristic group. Such doublets or triplets are often repeated, and if the harmonic law was a general one we should expect the wave lengths of these groups to be ruled by it, but such is not the case. The sodium lines which lie in the visible part of the spectrum are all doublets, the components being the closer together the more refrangible the group. But neither are the lines themselves in any simple ratios of integers, nor do the distances between the lines show much regularity. The ultra violet lines of sodium as photographed by Laveug and Dewar are single, with the exception of the least refrangible of them (3301). But this line is a very close doublet, and it may be that the others will ultimately be resolved. Some elements, such as magnesium, calcium, zinc, cadmium, show remarkable series of triplets, and the relative distances of the three lines seem well maintained in each of them. Even the distances when mapped on the wave number scale are so nearly the same for each element that it would be a matter of great importance to settle definitely whether the slight variations which are found to exist are real or due to errors of measurement. In the following table (II) we give the position of the least refrangible line of each triplet together with the distances between the first and second (column B) and between the second and third line of each triplet (column C). The figures in column A represent the number of waves in one millimetre. For the zinc and calcium triplets the measurements of Laveug and Dewar are given, the magnesium triplets are put down as measured by Cornu as well as by Hartley and Adeney. The differences in these measurements will give an idea of the degree of uncertainty. The triplets of cadmium are farther apart and are mixed up with a greater number of single lines.

*Relation between Spectrum of a Body and
Spectra of its Compounds*

The spectrum of a body is due to periodic motion within the molecules. If we are justified in believing that the molecule of mercury vapour contains a single atom, it follows that atoms are capable of vibration under the action of internal forces, for mercury vapour has a definite spectrum. We may consider, then, the spectrum to be determined in the first place by forces within the atom, but to be affected by the forces which hold together the different atoms within the molecule. The closer the bond of union the greater the dependence of the vibrations on the forces acting between the different atoms. Experimental evidence seems to favour these views, for we observe that whenever elements are loosely bound together we can recognize the influence of each constituent, while in the compounds which are sufficiently stable to resist the temperature of incandescence the spectrum of the compound is perfectly distinct from the spectra of the elements. The oxides and haloid salts of the alkaline earths, for instance, have spectra in which we cannot trace the vibrations of the component atoms, but the spectra of the different salts of the same metal show a great resemblance, the bands being similar and similarly placed. The spectrum seems displaced towards the red as the atomic weight of the haloid increases. No satisfactory numerical relationship has, however, been traced between the bands. The number of compounds which will endure incandescence without decomposition is very small, and this renders an exhaustive investigation of the relationship between their spectra very difficult.

The compounds whose absorption spectra have been investigated have often been of a more unstable nature, and, moreover, dissociation seems going on in liquid solutions to a large extent, the influence of the component radicals in the molecule is more marked in consequence. Dr Gladstone,¹ at an early period in the history of spectrum analysis, examined the absorption spectra of the solution of salts each constituent of which was coloured. He concluded that generally, but not invariably, the following law held good: "When an acid and a base combine each of which has a different influence on the rays of light a solution of the resulting salt will transmit only those rays which are not absorbed by either, or, in other words, which are transmitted by both." He mentions as an important exception the case of ferric ferro cyanide, which, when dissolved in oxalic acid, transmits blue rays in great abundance, though the same rays are absorbed both by ferro cyanides and by ferric salts. Soret has confirmed, for the ultra-violet rays, Dr Gladstone's conclusions with regard to the identity of the absorption spectra of different chromates. The chromates of sodium, potassium, and ammonia, as well as the bichromates of potassium and ammonia, were found to give the same absorption spectrum. Nor is the effect of these chromates confined to the blocking out simply of one end of the spectrum, as in the visible part, but two distinct absorption bands are seen, which seem unchanged in position if one of the above mentioned chromates is replaced by another. Chromic acid itself showed the bands, but less distinctly, and Soret does not

consider the purity of the acid sufficiently proved to allow him to draw any certain conclusion from this observation. Erhard's work on the absorption spectra of the salts in which chromium plays the part of base has already been mentioned. Nitric acid and the nitrates of transparent bases, such as potassium, sodium, and ammonia, show spectra, according to Soret, which are not only qualitatively but also quantitatively identical, that is to say, a given quantity of nitric acid in solution gives a characteristic absorption band of exactly the same width and darkness, whether by itself alone or combined with a transparent base. It also shows a continuous absorption at the most refrangible side, beginning with each of the salts mentioned at exactly the same point. The ethereal nitrates, however, give different results. In 1872 Hartley and Huntington examined by photographic methods the absorption spectra of a great number of organic compounds. The normal alcohols were found to be transparent to the ultra violet rays, the normal fatty acids less so. In both cases an increased number of carbon atoms increases the absorption at the most refrangible end. The fact that benzene and its derivatives are remarkable for their powerful absorption of the most refrangible rays, and for some characteristic absorption bands appearing on dilution, led Hartley to a more extended examination of some of the more complicated organic substances. He determined that definite absorption bands are only produced by substances in which three pairs of carbon atoms are doubly linked together, as in the benzene ring. More recently he has subjected the ultra violet absorption of the alkaloids to a careful investigation, and has arrived at the conclusion that the spectra are sufficiently characteristic to "offer a ready and valuable means of ascertaining the purity of the alkaloids and particularly of establishing their identity." "In comparing the spectra of substances of similar constitution it is observed that in such as are derived from bases by the substitution of an alkyl radical for hydrogen, or of an acid radical for hydroxyl, the curve is not altered in character, but may vary in length when equal weights are examined. This is explained by the absorption bands being caused by the compactness of structure of the nucleus of the molecule, and that equal weights are not molecular weights, so that by substituting for the hydrogen of the nucleus radicals which exert no selective absorption the result is a reduction in the absorptive power of a given weight of the substance. Bases which contain oxydized radicals, as hydroxyl, methoxyl, and carboxyl, increase in absorptive power in proportion to the amount of oxygen they contain."

It would seem, however, by comparing the above results with those obtained by Captain Abney and Colonel Festing² that the absorption of a great number of organic substances is more characteristic in the infra red than in the ultra violet. Some of the conclusions arrived at by these experimentalists are of great importance, as the following quotations will show:—"Regarding the general absorption we have nothing very noteworthy to remark, beyond the fact that, as a rule, in the hydrocarbons of the same series those of heavier molecular constitution seem to have less than those of lighter." This effect agrees with the observations made by Hartley and Huntington in the ultra violet, in so far as a general shifting of the absorption towards the red seems to take place as the number of carbon atoms is increased. Such a shifting would increase the general absorption in the ultra-violet as observed by Hartley and Huntington, and decrease it in the infra red as observed by Abney and Festing. Turning their attention next to the sharply defined lines, the last named, by a series of systematic experiments, concluded that these must be due to the hydrogen atoms in the molecule. "A crucial test was to observe spectra containing hydrogen and chlorine, hydrogen and oxygen, and hydrogen and nitrogen. We therefore tried hydrochloric acid and obtained a spectrum containing some few lines. Water gave lines, together with bands, two lines being coincident with those in the spectrum of hydrochloric acid. In ammonia, nitric acid, and sulphuric acid we also obtained sharply marked lines, coincidences in the different spectra being observed, and nearly every line mapped found its analogue in the chloroform spectrum, and usually in that of ethyl iodide. Benzene, again, gave a spectrum consisting principally of lines, and these were coincident with some lines also to be found in chloroform. It seems, then, that the hydrogen, which is common to all these different compounds, must be the cause of the linear spectrum. In what manner the hydrogen annihilates the waves of radiation at these particular points is a question which is, at present at all events, an open one, but that the linear absorptions, common to the hydrocarbons and to those bodies in which hydrogen is in combination with other elements, such as oxygen and nitrogen, are due to hydrogen, there can be no manner of doubt. The next point that required solution was the effect of the presence of oxygen on the body under examination. It appears that in every case where oxygen is present, otherwise than as a part of the radical, it is attached to some hydrogen atom in such a way that

¹ Measured by Thalen.

² Measured by Liveing and Dewar.

³ Phil Mag., xiv p 418 (1857)

⁴ Phil Trans., part ii (1885)

⁵ Phil Trans., iii p 887 (1881)

it obliterates the radiation between two of the lines which are due to that hydrogen. If more than one hydroxyl group be present, we doubt if any direct effect is produced beyond that produced by one hydroxyl group, except a possible greater general absorption, a good example of this will be found in cinnamic alcohol and phenyl propyl alcohol, which give the same spectra as far as the special absorptions are concerned.

Hitherto we have only taken into account oxygen which is not contained in the radical, when it is so contained it appears to act differently, always supposing hydrogen to be present as well. We need only refer to the spectrum of aldehyde, which is inclined to be linear rather than banded, or rather the bands are bounded by absolute lines, and are more defined than when oxygen is more loosely bonded.

"An inspection of our maps will show that the radical of a body is represented by certain well marked bands, some differing in position according as it is bonded with hydrogen, or a halogen, or with carbon, oxygen, or nitrogen. There seem to be characteristic bands, however, of any one series of radicals between 1000 and about 1100, which would indicate what may be called the central hydrocarbon group, to which other radicals may be bonded. The clue to the composition of a body, however, would seem to lie between λ 700 and λ 1000. Certain radicals have a distinctive absorption about λ 700 together with others about λ 900, and if the first be visible it almost follows that the distinctive mark of the radical with which it is connected will be found. Thus in the ethyl series we find an absorption at 740, and a characteristic band, one edge of which is at 892 and the other at 920. If we find a body containing the 740 absorption and a band with the most refrangible edge commencing at 892, or with the least refrangible edge terminating at 920, we may be pretty sure that we have an ethyl radical present. So with any of the aromatic group, the crucial line is at 867. If that line be connected with a band we may feel certain that some derivative of benzene is present. The benzyl group shows this remarkably well, since we see that phenyl is present, as is also methyl. It will be advantageous if the spectra of ammonia, benzene, aniline, and dimethyl aniline be compared, when the remarkable coincidences will at once become apparent, as also the different weighting of the molecule. The spectrum of nitro benzene is also worth comparing with benzene and nitric acid. In our own minds there lingers no doubt as to the easy detection of any radical which we have examined, and it seems highly probable by this delicate mode of analysis that the hypothetical position of any hydrogen which is replaced may be identified, a point which is of prime importance in organic chemistry. The detection of the presence of chlorine or bromine or iodine in a compound is at present undecided, and it may well be that we may have to look for its effects in a different part of the spectrum. The only trace we can find at present is in ethyl bromide, in which the radical band about 900 is curtailed in one wing. The difference between amyl iodide and amyl bromide is not sufficiently marked to be of any value."

The absorption spectra of the didymium and cobalt salts afford many striking examples of the complicated effects of solution and combination in the spectra. It is impossible to explain these without the help of illustrations, and we must refer the reader, therefore, to the original papers.¹ Some very interesting changes have been noticed in the position of absorption bands when certain colouring matters are dissolved in different liquids. Characteristic absorption bands appear for each colouring matter in slightly different positions according to the solvent. Hagenbach, Kraus, Kundt,² and Claes³ have studied the question. In a preliminary examination Professor Kundt had come to the conclusion that solvents displaced absorption bands towards the red in the order of their dispersive powers, but the examination of a greater number of cases has led him to recognize that no generally valid rule can be laid down. At the same time highly dispersive media, like bisulphide of carbon, always displace a band most towards the red end, while with liquids of small dispersion, like water, alcohol, and ether, the band always appears more refrangible than with other solvents, and as a general rule the order of displacement is approximately that of dispersive power.

Relations of the Spectra of Different Elements

Various efforts have been made to connect together the spectra of different elements. In these attempts it is generally assumed that certain lines in one spectrum correspond to certain lines in another spectrum, and the question is raised whether the atom with the higher atomic weight has its corresponding lines more or less refrangible

No definite judgment can as yet be given as to the success of these efforts. Leecoq de Boisbaudran has led the way in these speculations, and some of the similarities in different spectra pointed out by him are certainly of value. But whether his conclusion, that "the spectra of the alkalis and alkaline earths when classed according to their refrangibilities are placed as their chemical properties in the order of their atomic weight," will stand the test of further research remains to be seen. Chamician⁴ has also published a number of suggestive speculations on the question, and Hartley⁵ has extended the comparison to the ultra-violet rays.

When metallic spectra are examined it is often found that some line appears to belong to more than one metal. This is often due to a common impurity of the metals, but such impurities do not account for all coincidences. The question has been raised whether these coincidences do not point to a common constituent in the different elements which show the same line. If this view is correct, we should have to assume that the electric spark decomposes the metals, and that the spectrum we observe is not the spectrum of the metal but that of its constituents. Further investigation has shown, however, that in nearly all cases the assumed coincidences were apparent only. With higher resolving powers it was found that the lines did not occupy exactly the same place. With the large numbers of lines shown by the spectra of most of the metals some very close coincidences must be expected by the doctrine of chances. The few coincidences which our most powerful spectroscopes have not been able to resolve are in all probability accidental only. (A 5*)

SPEECH-SOUNDS, the sounds actually used for the conveyance of thought by speech. See **PHONETICS**.

1 **Symbolization**—It is necessary to have some system of writing speech sounds, in order to talk of them. The system used in the present article is the palaeotype of the present writer's *Early English Pronunciation*. All letters or words thus written will be enclosed in (). The following preliminary list of the ordinary sounds, with examples, will render what follows intelligible. For an alphabetical list, see art 20.

English—1 beet batt baa bought boat boot (but beet baa bat boot bunt) 2 knot net goat knot net nook (net net net not not not) 3 fife foil foel fuel (fa'il fo'il fa'ul fiun il) 4 hay (hee) 5 pea beg, toe doe, cape gape (pi bi, too doe, keep geep) 6 whey way, feel real, thin thou, seal seal, rush rouge, hoo you (whee wee, fil vul, thin dhen, sul zul, rosh runzh, jhuu juu) 7 ear ring, gull little (u' riq, gl' lit l) 8 sunn chasm, sunn open, sunn (sunn kær'in, soun oop'in, soq) 9 chest jest (tjest djest)

Foreign—F French, G German, I Italian 10 b'to F, l'cho R, nò R, d'è F, f'u F, v'uf F, u'u F, v'ut F, v'out I, u'u F, s'ou I, s'oi F, l'u F (beet, laash, no, dy, f, v'ef, v'ov, v'ov, v'ov, v'ov, s'ue, s'ua, ly) 11 dach touch, tage siege, wahl, all a (dakh taukh, tanghu, zughu, bhaal) 12 paglia I, bisogno I (pi lu, b'zou)

2 **Nature of Speech-Sounds**—Speech-sounds result from shocks given to the air by the organs of speech, received by the drumskin of the ear, and transmitted to the auditory nerves in the cochlea. The apparatus is explained by Helmholtz, who deals with musical sounds. But speech is not musical, and its sounds are much obliterated when rendered musical.⁶ An original quality of tone generated by the vocal chords is modified by the cavities through which it passes, as explained by Helmholtz (*Sensations of Tone*) on the principle of resonance. There are three ways in which speech sounds may be produced—(1) by the air in the mouth, without additional breathing, by smacks and clicks, (2) by drawing in air, as orally in chirps, whistles, sobs, gasps, and nasally in snuffles, snores, (3) by expelling air, as in the greater number of speech sounds. The last are

⁶ Ellis, *Speech in Song*, sect. iv

the position for (j) tight up against the extreme back of the hard palate so as to produce a complete stop. The most important of the palatalized letters are (lj, nj), tho Italian *gli, gn* in *miglior, ognor* (milyō r, onjō r), where the palatalization brings the Italian advanced (l, n) to the position of the English (lj, nj). The (lj) has degenerated to (j) or (ɟ) in France during the 19th century. It exists in Spanish *ll*, Portuguese *lh*. The (nj) exists as *gn* in French, *ñ* in Spanish, and *nh* in Portuguese.

Parallel to the palatal are the labial forms, of which English *queen, guano* (kwīn, gwā nō) are examples. They seem to exist in abundance in French, as in *toi, doigt* (twa, dwa). The palato-labial form (wɟ), as in *juin* (zhuɟwā), is much disputed, and a diphthong (zhywā) is usually assumed.

13 *Syllables*.—A group of speech sounds increasing in volume from a mute, sonant, hiss, buzz, or flap to a full vowel and decreasing again to one of the former constitutes the ideal syllable (συλλαβή, collection). The initial and final parts may sink to clear glottids, and the middle part to a simple vowel. The type of a syllable is then < >, crescendo followed by diminuendo, as in (aa lant, thant, stant), theoretical, and (djədj, streɟkth, twelfths), actual syllables. The hisses or recoil before or after a stop are not felt as belonging to fresh syllables, because they have no vowel, which is the soul of the syllable. Monosyllables present no difficulty, but the division of syllables in polysyllables is not easy to understand. In (pɪ + p + ɪq) the middle (p) ends one set of glides and begins another. One syllable ends and the other begins with the assumption of the (p) position which is absolutely mute, so that the end of the first and the beginning of the second syllable are simultaneous, as the end of one hour and the beginning of the next. In this case (p) is said to be "medial." But there may be and often is a sensible pause between the two syllables, and then (p) is said to be "double," as (pɪ + pp + ɪq, pɪppɪq), in which case no recoil can be used, as (pɪp'pɪq). In "syllabizing," a totally artificial process, doubling is necessary, and very frequently the recoil is used, but it never is in speech. In (sɪ + s + ɪq) ceasing, there is a sensible hiss between the glides which end the first syllable and those which begin the second, and the syllable divides during that hiss. If we wished to produce the effect of doubling, we must break the hiss into two either by a silence or a diminution of force, as (missent). The same remarks hold for sonants, buzzes, and flaps, where we have a sensible voice sound during which the syllable divides. Syllables may even divide during a vowel, as French *payen, foyence, vaillant* (pɪeɪ, faɪas, vaɪas), where the syllable divides during (i), which may even be lengthened to show the two syllables, but, if the syllables have to be sung to notes with a pause between them, we must double the (i), thus (pɪ iea, faɪ ias), as either (pɪ ea, faɪ aas) or (pɪ ieɪ, faɪ ias) would be unintelligible. The sensation of separate syllables is always easy. It is the essence of versification, the oldest form of literature.

14 *Accent and Emphasis*.—Generally several syllables form a single word, and in many languages—by no means all languages—one syllable in a word is rendered conspicuous. Several plans have been adopted for this purpose. (1) Quantity or length of syllables, which seems to be all that is known to modern Indians, Arabs, and Persians. (2) Heightened or lowered or descending gliding pitch (*conportamento*) of one syllable, which were the acute, grave, and circumflexed syllables of Sanskrit, Latin, and Greek, the position of these syllables in a word there depending partly on the quantity of the syllables and partly on sense, this pitch difference remains in a more complicated form in Norwegian and Swedish. (3) Greater force given to one syllable, this is the English, German, and Italian "stress," and from the end of the 3d century A.D., when the feeling

for quantity faded, was used instead of high pitch in Latin and Greek. The modern Italian and modern Greek as a general rule preserve the memory of the syllable which had the high pitch by giving it greater force, with but few exceptions, as Italian *cade re ri dere*, to fall, to laugh. (4) By a peculiar pronunciation, as the "catch" of the Dance. In French none of these methods seem to be consciously adopted. Some declare that the last syllable (not counting mute e) always has the stress, others that it never has the stress, others, again, consider the stress to be intentionally even, and when altered to depend mainly on grammatical construction, while there is certainly a raised pitch, frequently towards the close of a phrase or sentence, but sometimes on a penultimate syllable. Turks and Japanese have also even stress. All these modes of rendering a syllable conspicuous are apt to be called "accent," the Latin translation of *-prosōdia*, the song added to the word, which properly applied to class (2) only. Where pitch accent prevailed there may have been also stress, but that stress was probably as little subject to strict rule as alteration of pitch is in English speech, where it undoubtedly exists, without properly affecting signification. Hence we may say roughly that in Latin and Greek pitch was fixed and stress free, but in English and German stress is fixed and pitch free.

What accent is to a word, emphasis is to a sentence. But there is this difference. Accent always falls on a fixed syllable of a word. Emphasis varies with the word to be made conspicuous. Emphasis does not consist merely in making the stressed syllable of a word louder. It depends upon a number of most subtle varieties of qualities of tone, length, and pitch of utterance,—in short, of those tricks and wiles of speech which form the stock-in-trade of actors and orators. The same words will mean totally different things according to the place and nature of the emphasis used. Different nations emphasize differently. To an Englishman French emphasis is apt to seem placed on the wrong word.

15 *Intonation*.—Although musical accent does not exist in English, almost every country has its peculiar sing-song mode of utterance. And even among educated men the sing-song may frequently be heard in public speaking, or in declaiming poetry, or recitation, or reading aloud generally. For these things no invariable rule exists. But in England questions require the pitch of the voice to be raised and affirmations to be lowered, towards the end of a clause. In Scotland the pitch is raised in both cases, so that to an Englishman a Scotchman seems to be always asking questions.

16 *Analysis of Speech-Sounds*.—What is heard are sentences consisting of various fixed sounds cemented by gliding sounds, which act one on the other, and thus become greatly modified. To construct an alphabet it is necessary from this mass to separate the fixed elements and the changing glides, to crystallize them into symbols, and finally to make the value of those symbols known to the reader. The last cannot be done satisfactorily except by viva voce instruction, but much can be accomplished by a review of the relations of sounds, made dependent on the relations of the motions of the organs of speech by which they are produced. There is a preliminary difficulty in defining an element. Perhaps position, flatus, whisper, and voice are the only ultimate elements. But it is usual to be very lax. Thus (p, t, k) have position only, (f, s, sh, kh) position and flatus, (i, a, u, w, z, zh, gh) position and voice. The analysis is therefore only into "proximate" and not "ultimate" elements. Again, when a new mass of sound is presented to the ear, a long time passes before the ear becomes sufficiently accustomed to the sound to distinguish the proximate elements and their combinations,

and therefore before the voice can imitate them at all satisfactorily. Hence the best phonetists differ. It may certainly be considered impossible from a knowledge of a few languages to construct an alphabet which will serve for all. Nevertheless a consideration of some partial schemes is of great value as a stepping stone. We give Mr Melville Bell's vowel system and Mr Henry Sweet's alteration of Mr M Bell's consonant system, both supposed to be universal, but neither properly appreciating Asiatic, African, and American-Indian languages and habits of speech. After these follows a modification of a confessedly partial system by the present writer, applying chiefly to English, German, Italian, Spanish, and French, with a few partly theoretical sounds, introduced to show connexions. In all these the sounds will be expressed by palacotype symbols without any explanation in the tables themselves, because that is furnished at better length than would there be possible in the alphabetical list of art 20.

17 *Mr Melville Bell's "Visible Speech" Vowels*—These are arranged primarily according to the height of the tongue, which is supposed to be divided into "back" and "front" or central part, beyond which lies the "point." The heights refer first to the "back" and lastly to the "front," and between them lie the "mixed," for which both back and front are more raised than the "front," so that there is generally a hollow between them. Each set is then divided into "narrow" and "wide," the precise meaning of which, as stated in art 4, is not settled. Finally come the "rounded" vowels, there being three degrees of rounding,—one for "high," one for "mid," and one for "low" tongue. For convenience here the back, the mixed, and the front are formed into separate groups, and all the vowel signs are numbered, being referred to in the following lists by V and the number, thus V4 is (u), which in Mr Bell's nomenclature would be called "high back wide round." The letters n, w, nr, wr at the heads of columns mean "narrow, wide, narrow round, wide round."

Mr Melville Bell's "Visible Speech" Vowel Table

Tongue Height	Tongue Back				Mixed				Tongue Front			
	n	w	nr	wr	n	w	nr	wr	n	w	nr	wr
High	1 æ	2 u	3 u	4 u	11 æ	14 y	15 u	16 u	25 i	26 a	27 i	28 y
Mid	5 æ	6 a	7 o	8 o	17 æ	18 a	19 o	20 u	29 e	30 o	31 e	32 o
Low	9 æ	10 a	11 a	12 o	21 æ	22 a	23 a	24 o	33 e	34 o	35 e	36 o

These positions being insufficient, although supposed to be precisely known, may be "modified" by raising the tongue more (a') or lowering it more (a₁), or bringing it nearer the teeth (a) or nearer the throat (a₂). And, even this not sufficing, Mr Sweet has contrived a number of new modifiers, here passed over. And with all this none of the sounds can be produced purely through any position without an effort of will dependent on a conception of the sound. The characteristic of the vowel notation contrived by Mr Bell is that each sign shows at once the position of the sound in the Table.

18 *Mr Henry Sweet's "Sound Notation" Consonant Table*

	Tongue Back	Tongue Front	Tongue Point	Point Tooth	Diade	Blade Point	Lips	Lip Back	Lip Teeth
Voiceless Consonants									
1 Open	kh	jh	rh	th	s	sh	ph	wh	f
2 Divided	th	lh	lh	lh			ph ₁		
3 Shut	k	g	t	ch			m		
4 Nasal	q	qj	nh	nh			mh		
Voiced Consonants									
5 Open	gh	j	r	dh	z	zh	bh	w	v
6 Divided	l	lj	l	l			bh ₁		
7 Shut	g	g	d	d			b		
8 Nasal	q	qj	n	n			m		

These signs will be referred to as SSc, or Sweet, line 8, col c, giving (u). The consonants are modified in a similar manner to the vowels. Columns a, b, c indicate straits or contacts between the palate and the parts of the tongue named by the "blade" is meant the part of the tongue between the "front" and the "point." Mr Sweet's substitutes for glottids and pharyngals, and his and Mr Bell's notation of glides are omitted for brevity. Their notation throughout is entirely different from that here used.

19 *A J Ellis's partial schemes, modified from his Speech in Song*

Vowel Trigram									
1 i	2 i	3 e	4 e	5 r	6 o	7 a	8 a	9 a	10 a
11 u	12 u	13 o	14 o	15 o	16 a	17 a	18 a	19 a	20 a

The meaning of this arrangement is that, if we pronounce the vowels in the order of the numbers, they will form a sufficiently unbroken series of qualities of tone, or, if each line be so pronounced leading to 8=22a, three series of the same kind are produced, and also that the speaker feels that the vowels in the middle line lie "between" the vowels in the first and third lines between which they are written. These intermediate characters refer only to qualities of tone and not to the vowel positions, as they apparently did in the older "vowel triangles" from which the trigram is adapted. The arrangement of Mr Bell is excellent for showing the relations of the positions, but gives no more clue to the relations of sound than the indispensable ratios 1 2, 2 3, 3 4, 4 5, 5 6 give to the musical sensations of the intervals known as the octave, fifth, fourth, major third, and minor third. Hence the advantage of this additional arrangement. It will be referred to as 1 G, that is, trigram, vowel 6, or (e).

A (a ah a' a' n aa a'y, a', a ah, a, u)

- (a) V 6, T 8 = T 22, short a man, long i father, art 6
 (ah) V 18, T 7, oee i pass, path
 (a') art. 7 i, unanalysed diphthong, i eye, a e
 (a' n) art. 7 ii, unanalysed diphthong r hoie, a hau
 (a v) art. 11, F cent, a conventional form
 (a'y) art. 7 iii, unanalysed a frende, often (v)
 or (a) with higher tongue, 17 and 18 short a, nearly = (ah)
 (a')
 (a) V 10, T 9 B hears it in r father, arms, aims, I, doc not Sw and E hear it in is father, E and LLB in F diable, E in i pte, pte
 (ah) V 23 B says (a) with advanced tongue = (a), (a) on the road to (a)
 (A) V 11, T 10, short open in r authority, long closed r and almost peculiarly r

- (v) V 2, T 19 B hears it in *Edngcon*, motion, conscious, abandon, honour, bellows. E hears it in these syllables and in *eparental*, capable, capacious, China, and *o gabe* Sw and Sv hear (ə) in all these cases.

Æ (e, eh)

- (v) V 34, T 6, *ægnat*, almost peculiarly *æ*.
(æh) V 36 B hears it as a Cockney substitute for *ou*, *ow* in *out*, *now*, which E, a born Londoner, does not know Sv finds it to be "open" *æ*, see (j).

B (b bh brh, b₁, bh₁, B)

- (b) S 7 g, C u 13, art. 8, *bee*, *ebb*
(bh) S 5 g, C u 12, *g w*, lips flat, not touching teeth, see (ph)
(brh) C u 13, used by Germans to stop horses, as *tro* ' is in England.
(b₁) C u 12, sonant of (p₁), which see, theoretical
(bh₁) S 6 g, sonant of (ph₁), which see, theoretical
(B) C u 11, sonant of (P), which see, theoretical

C (c ch, c' t, ç ch, ç ch)

- (c) V 12, T 11, *E knot*, almost peculiarly *E*, replaced on the Continent by (o, oh, oh), which see
(ch) V 24 B calls it an advanced (c), that is (c'), and hears it as regular short Irish English *c*, Cockney *ash*, American Chicago Sw hears it in *swd son*. Sv gives no example E does not know it
(c' t) art. 7 i, diphthong *E foil*, by some taken as (A' t)
(ç) reverted (s), the under part of the point of the tongue against the palate. St.¹ hears it in East Norwegian *borse* and also in *swd*
(ch) reverted (sh), *s v* *ç*, the under part of the point of the tongue against the palate, but lower than for (ç) and pointing further back, see (tj)
(c) buzz of (ç), theoretical
(ch) reverted (zh), buzz of (ch), see (vj).

D (d d₁ dh d₂, d, dh, d', d d₁ dh, d d₂)

- (d) S 7 c, C u 8, *F doe*, sonant of (t), which see
(d₁) art. 12, *E jwāng*, consonantal diphthong = (djzlj), usually assumed as (dzlj), and also as *s v* *ç*, for which see (gj), and *AR ç*, which Lepsius thinks was also once (gj)
(dh) S 5 d, C u 10, *E then*, *MC ð*, *AP ð*, buzz of (th), see (dh)
(d₂) C u 6, Hungarian *gyongy*, pearl, art. 12.
(d) S 7 d, C u 9, *F doux*, tip of tongue against gums, used in some midland and northern E dialects before *r*, -*er*
(dh) C u 10, *sp lid*, lisped (z), retracted (dh)
(d) *daad*, described by Lepsius as close emphatic (, 1'), see (s, t, z) and especially (k)
(v) C u 7, reverted or cerebral *s v* *ç*, common in south west England, in connexion with (P), which see, by some taken to be retracted (d₁), parent of *E* (d)
(vj) a reverted consonantal diphthong = (D + çh), heard in Wiltshire (*arvj*) ridge
(dh) reverted (dh), under part of point of tongue against teeth, theoretical
(v) Irish Gaelic *dair*, an oak, "broad" post-aspirated sonant. The place of tip of tongue unimportant, but generally taken as dental or interdental. Essential points, tongue laterally expanded and slack, back raised, leaving a hollow "front." Followed by a slow voice glide, resembling a preponderating *E* (sh) mixed with (gh). This glide, occurring between a sonant and a vowel, is closer at first than for an ordinary buzz and then more open. Constantly used for (dh) by Irish speakers of *E*. [Lecky, MS communication]
(vj) Irish Gaelic *deas*, palatalized or slender (v), glide from it like preponderating (j) mixed with (z) [Lecky, MS communication]

E (e e₁, e, E, e oh, e₁, e ch, e₁, e, e' o)

- (e) V 30, T 4, *F net*, *sr e*, medial between *F* and *it* close and open (e, E), often (E) in dialectal *E*. B hears it only long in *E* there Sw gives *F päre*, which E hears with (EE) Sv gives *E men*, *g männer*, *ähre*, *træ*. LLB hears it always and only in unaccented *it* syllables.
(e₁) art. 11, orinatal, *F vin*, conventional symbol
(e) V 29, T 3, *F dé*, *g chre*. B says it is found in *E* always and only in the vanish (e' j), art. 6, but E hears the vanish from received speakers only in the pause, otherwise he frequently hears (ee) without vanish. Sw, S₁, and St. do not admit (ee) in *E* without vanish.
(E) V 33, T 5 B considers it the regular *F* sound in *net*, see (e) F hears it long in *G spräche*, *F bete*, it open *e* Sw hears it in *E air*, *is men*, *F vin* (vEa) S₁ also in *dv lara*
(e) V 17, T 20 E hears it in his *F nut*, which B wrote (nrt) from

E's dictation, many think (e, e) are used respectively in *F* accented and unaccented syllables where E hears (e, v), and he is very familiar with (e) in dialects Sv gives "stago *e* ' gibe, *dv* normal *gave*, *swd* *gosse*."

- (eh) V 21 Sw gives *r bird*, where E hears (ə) B heard it only in Somerset *sir* and Cockney *penny*, the whole effect of the first appears to E due to Somerset (u), the second he does not know
(e₁) intermediate between (e) and (i), written *u* in Mr Elworthy's West Somerset grammar, very common and characteristic sound in the dialect, but difficult and strange beyond it.
(e) V 31, T 17, *F feu*, *pcu* B hears it in *F dā*, *būt* and in *is* E hears it long in *g hülle* Sv says the *g* sound is (æw), not (w), see (j)
(eh) V 35 B hears it long in *F peur*, *g schöne*, &c., short in *F jeune*, *g stöcke*. E hears (ə) in *schöne* and (æ) in the rest. See Sv in (j).
(e₁) intermediate between (e) and (æ), a common west Somerset sound, possibly S₁'s "open *e* u" See under (y)
(a) V 5, T 21 B hears it in *r done*, *young*, *up*, *troupe*, where it sounds dialectal to E, who hears (ə), which see.
(e' o) art. 7 ix, acute inchoant diphthong

F (f, j)

- (f) S 1 z, C u 11, *r feel*, lower lip against upper teeth
(j) a turned *f*, a modifier, laxly used, see mute and sonant (hj, gj), lateral flap (lj), nasals (nj, dj) and consonant diphthongs (tj dj, tj dj)

G (g gj gh gj gh gh gw gwh, g ch)

- (g) S 7 a, C u 3, art. 8, *E gipe*, *egg*
(gj) S 7 b, C u 5, *s v* *ç*, sonant of (hj), which see, and also (dj)
(gh) S 5 a, C u 3, mud *g tage*, buzz of (kh), which see, and also (gjh, gwh)
(gj) C u 4, *it la glianda*, sonant of (hj), which see, formerly common in *i* before (a, æ), as *guard*, *garrison*, now generally preserved in *girl*, even in the vulgar form (*gjæl*)
(gjh) C u 4, mud *g siege*, buzz of (kh), which see, confused by Germans themselves with (j), palatalized (gh)
(grh) C u 13, *AR ç* (grhain), or (gh) with the uvula slightly trilled, frequent Dutch *g*, *mo* *γ* before (a, o, u) in a mild form, Lepsius takes the *AR* sound to be (rh), which see
(gw) art. 12, C u 2, *E guano*, sonant of (kio), which see, the positions for (g) and (w) are assumed at the same time
(gwh) C u 2, *g auge*, fuge, sonant of (kch), which see, labialized (gh) after (u)
(g) C u 1, sonant of (κ), which see, theoretical
(gh) buzz of (g), see above under (grh)

H (h h₁ h₂ h₃, h, H, H₁h)

- (h) when no letter, and, at most, some sign precedes, used for the unanalysed phylem, art. 5, after a letter very laxly used as a modifier of vowels (ah oh), and consonantal hussas or buzzes (th dh sh zh kh gh), &c.
(h₁) simple flatus, the (h) omitted when another letter precedes, as in the recoil (*hep*) *hap*, art. 8
(h₂) the crudest voice producible, opposed to (h₁), the (h) omitted in the voiced recoil (*ded*) *dead*, art. 8, and in (*l*, *m*, *n*, *r*) syllable
(h₃) smack or click, art. 2, (1), the (h) is omitted after consonants showing the clicking parts, as (k₁ t₁ t₁ t₁ t₁ t₁) guttural, palatal, alveolar, dental, and reverted click, see the turned numerals (8 f l g z), which are used for brevity
(h) art. 5, phylem (2), the *AR ç* (*haa*), or "wheeze."
(H) art. 5, phylem (1), the "jerk" or unflated aspirate, used as post aspirate after Indian sonants, as *s v* *ç* (*bue*)
(Hh) jerked flatus with gradual glottid, art. 5, phylem (1), the usual aspirate of Scotland and Germany, and the Indian post-aspirate after mutes, thus *s v* *ç* *mare* (*kh*, *th*, *ph*), usually written *kh*, *th*, *ph*, but not to be confused with the palaeotype (*kh*, *th*, *ph*)

I (i ia ii, i i₁, i)

- (i) V 25, T 1, short *F fil* (very different from *E fill*), long *E feel*
(ia) art. 7 iv, typical initial weak (i) diphthong, often confused with (ja)
(ia) art. 7 vii, typical murmur diphthong with following permissive trill
(i) V 26, T 2, *E knit*, almost peculiarly *E* and Icelandic, but often heard in *German*, long *r* (ii) is often replaced by (i), especially before and after (r) and in singing
(i) art. 7 ix, typical grave inchoant diphthong
(i) V 27 B hears it in *g über*, *glück*, Sw in *F lune*, where B hears (j), E inclines to (i) in *o*, but S₁ thinks differently, see (j)

- J (j) j, j sh)
(j) a modifier, symbol of palatalization, art 12, but this simultaneous palatal action is constantly confused with successive (r, j)
(j) art. 7 m, used to express the vanish of (cc, c) towards (j), ending in an approach to the consonant (j), thus (cc'j, c'j) or (j) without a dot, marks a semipalatalization, the tongue being only approximated to the palatalizing position, observed in several Uralic languages by LLB
(j) S 5b, C 15, 1 rca
(jh) S 1b, C 15, 1 kow, huo (jlin), hiss of (j) very close to flated (m), art. 4
K (k k j k h k j k h k r h k w k w h, k k h)
(k) S 3a, C 13, 1 cipe, perfectly mute, art. 8
(kj) S 3b, C 15, 1 4, the "back" and "front" of the tongue brought closely into the (k) and (j) positions, forming a complete stop, the "point" may rest against the lower gums, and had better do so to avoid the jump up to (t) chest, with which this mute is constantly confused, but (tj) is more like 4 (kjuh) or post aspirated (kj), which supplies the necessary hiss
(kh) S 1a, C 13, 1 drck, 1 j, see (kjh k h)
(kj) C 14, 1 r l chive, palatalized (k), art 12 In the 17th and 18th centuries constantly used in r before (a, o), it may be now constantly heard in London before or in count, called (k'ant), or inner (k'ant) for (ka'ant)
(kjh) C 14, 1 r l chive, palatalized (kh), confused with (jh) by German theorists, but the back of the tongue is higher for (kjh) English people confuse it with conceiv (sh), which it ought never to approach, though it comes near conceiv (sh) Lather (kjh) or (kj), the hiss of (kj), which was not distinguished from (jh), was the original 4, now called (sh) and confused with 4, properly (jh), see under O
(kh) C 13, 1 u 4, a (kh) with the uvula slightly tilted, as in Dutch 4, Lepsius considers both to be (kh)
(kwo) C 12, art 12, 1 guoon (k'wou), not (k'wou)
(kwh) C 12, 1 u quhat (k'what), a much, back, art 12 labialized (kh)
(k) C 11, 1 u 4 (kaat), the tongue greatly retracted and wedged against the uvula Lepsius considers the proper sound of u 4 to be (o), the sonant of (k) By Syrian Moham medans and often by Egyptians the 4 is lost or rather becomes lamza (.), as (a' la) for (kaa la) said "Em phatic" character attaches to 4 4 ط ع ح ق here written (k k h g h t d s z), which Lepsius takes to have the values (a k u h d l, l, s, d h) respectively, this "consists in a modification of the vowel by narrowing [the passage below] the soft palate", these letters are called "high" by the Arabs because of this very high back of the tongue They call the emphatic pronunciation "thick, rough, fatty" In fact (a) becomes (e), (o) remains, (e, i) become (i, u), (u) is scarcely changed Europeans recog nize the consonants mainly by this vowel change
(kh) hiss of (k), considered by Lepsius to be the proper sound of what is here written as (kh)
L (l l j l h l h l j l s l h, l, l l h, l l h, l l h, l j, l j h, t)
(l) S 6c, C 11, art 10, 1 guh, tip of the tongue far behind the gums, replaced on the Continent by (l)
(lj) S 6b Sw says "(l) formed in the place of (r), and hears it in r gl, 1 l, in l h, where LLB and E hear (lj)
(ljh) S 2b B says it is "a variety of defective s," theoretical
(lh) S 2c, C 11, art 8, flated (l), not Welsh l B hears it before (t) in felt, as (f lht) E hears no trace of it, any more than he hears (t) in (wot)
(ly) C 11, art 12, 1 r gh, 1 l, 1 u h LLB and E hear this as a palatalized 4 (l), not Continental (l), the palatalization having retracted the (l)
(ls) C 11, art 8, voiced form or buzz of unilateral Welsh l, see (lsh)
(lsh) C 11, art 8, or more conveniently (lsh), Welsh lall, put tongue in position for (l), raise the left side to touch the palate, let flatus escape by the right side. The tongue is then in the position assumed after making the unilateral chek (tsh), see (tsh) under H This unilaterality is insisted on by Salesbury, and F was thus taught in Wales. Sw 2 also insists on it Some Welshmen do not.
(l) 4 lht, syllabic (l), the voice of the lateral flap sufficing to form a syllable when final
(l) S 6d, C 11, art 9, 1 lat, the tip of the tongue against the gums, as is usual out of England
(lh) S 2d, C 11, art 8, flated (l), see r people
(l) S 6a, PL guttural or "harred" l, that is, l with a slanting line drawn through it The back of tongue is raised as high as for (k) St. 3 finds r l after a vowel in the same syllable half guttural, this is unknown to Englishmen
(lh) S 2a B calls it "the hiss of a water fowl," the hiss of (l), theoretical
(L) C 11, art 7, reverted l, the underpart of the point of the tongue coming against the hard palate, used in conjunction with (u) in south west England, as world (w'ard' L) Those who used retracted (r) say (w'ard' L)
(lh) C 11, art 7, flated form of (l), theoretical
(l) Irish Gaelic "broad" l, as in all (the l being written singly because of the following t, at the end of a word it is always written ll, tongue in the same position as for (d), which see, but with the lateral omission of the l class [Locky, MS communication]
(h) Irish Gaelic "slender" ll, as in Irish Gaelic, mll, this bears the same relation to (l) as (tj) does to (t), see (tj) [Locky, MS communication]
(l) turned l, the gradual glottid, art. 5
(lh) an exaggerated form of the gradual glottid, art. 5, and see (m) under H
(t) turned l, DN ret, glottal: Douders says "sing a note as deep as possible, and then try to sing a lower one, the voice will be replaced by a peculiar crackling noise," which is (l), it is the common form of DN r
M (m m h m, m)
(m) S 8g, C 13, art. 11, 1 mummung
(mh) S 1g, C 13, flated form of (m) B hears it before mutes in place of (m), as camp (ka'mhp), E does not, art. 11
(m) syllabic m, 1 chasun (ka'm)
(w) turned m, C 12, 1 defective r in vewy (v'ewy) vewy, differ ing from (brh) by having tight and flat in place of loose and round lips, with minute instead of considerable exen sions of the lip
N (n n j n h n j, n n h, n, n, n n)
(n) S 8c, C 13, 1 no, tongue as for (t), mouth open or closed indifferently, as the tongue is an effectual stop, art. 11
(ny) a nasalized (lj), which those take to be r gn who assume r gl to be (lj), see (lj, qj)
(nh) S 4c, C 13, flated (n), used in Cumberland for initial kn, in know (nhoo) B hears it before mutes, as in bent (br'nt), E does not, see art. 11
(ny) nasalized (lj), the tongue lies along the palate in the same way as for (lj), but the nasal passages are now open LLB and E hear it as palatalized 4 (n), not (n), r gn, 1 n, 1 n h, r gn St. 3 takes the r sound to be (qj) L has not detected (qj) in native r speakers, after long continued express observation
(n) S 8d, C 13, 1 nam, tongue on gums
(nh) S 4d, C 13, flated (n), theoretical
(n) syllabic (n), r open (o'p'n)
(n) C 17, reverted (n), tongue as for (r), SN 4, south west r n in connexion with (u), as (harn) tau
(n) Irish Gaelic "broad" nn, as in dunt (the n not doubled because of following t), tongue as for (t, u), which see, but with nasal passages open [Locky, MS communication]
(ny) this bears the same relation to (n) that (tj) does to (t), Irish Gaelic "slender" nn, as in binn [Locky, MS communication]
O (o oh oa oy, o oh)
(o) V 8, T 12, short r open o, nd, long in r oro (oo), which is fast degrading in London to (aa'u)
(oh) V 20 Sw and Sv hear (oh) and neither (o) nor (oh) in r homme, which E hears as (om), very different from r (om) B hears (oh) in colloquial eloquence, philosophy, opinion, and American whole, in all of which E hears (o)
(oa) art. 11, r out, a conventional form, not to be confused with (a)
(oy) at. 7 m, theoretical form of o cu, see (a'y)
(o) V 7, T 13 B hears it short in r poor, moor, E in poetic, following B hears it when long in r always and only with the vanish (oo'ro), art. 6, art. 7 m E hears (oo'ro) in the pause, but otherwise generally (oo), and (don) is always erroneous.
(oh) V 10 B says this is a mixture of (o) with (i) or is (o) with advanced tongue, that is, (o), he hears it in r homme (ohm), where E hears (om), see (oh)
OE (æ æ a' æ, æ a' u, æ, æ u)
(m) V 32, T 18, 1 ænf, a becke See S under (y)
(æ) art. 11, ornasal r u, chaceu, conventional symbol
(æ') art. 7 m

1 Welsh / conclusion, 1:0

² "Broken North: Welsh in Trans Philol Soc., 1882-84, p. 418.

3 *Englische Philologie* I Die lebende Sprache, p. 71

4 Ibid., p. 47

- (æ) V1 B hears it in Scotch Gaelic *laogh*, it may be produced by saying (uu) and suddenly opening the mouth, see (æ'n)
- (æ'n) acute inchoant diphthong, art. 7 ix, or (uu), begun with the mouth open and without internal rounding, very common in south Lancashire and Cheshire
- (æ) V9 B makes it the "narrow" form of (æ), and the regular form of *ls up, come*, Sw occ. *ls form*
- (æ) V22. B hears it as the regular *æ* sound of *er, ur, yr* Sw hears it in the first element of *low* (*hæ'u*), which E. finds dialectal
- (æ) a dialectal south west English sound of (æ) through which a sound of (A, a) seems to run, and usually appreciated as the latter
- P (p ph prh, p, ph, r)
- (p) S3g, C13, E *peeping*, perfectly mute, art. 8
- (ph) S17, C12, Hungarian *f*, *mc* *φ*, an (f) spoken by the lips only without the teeth, mouth in position for blowing to cool, flated form of (bh), which see.
- (prh) C13, flated form of (brh), common with babies before they can speak.
- (p) C12, mute of (ph), the lips closed flat to form a complete stop, theoretical.
- (ph) S2g, middle of lips in contact, flatus expelled from each corner of the mouth, theoretical.
- (i) C11, mute of (f), lower lip forming a complete stop with upper teeth, theoretical.
- Q (q qj qjh qh qj)
- (q) S8a, Cx3, *r singer, finger*, (g) with nasal passages open
- (qj) S8b, Cx5, *s* *qj*, nasal of the palatal series, see (h j g)
- Bopp considers it to be *r gn*, and Sw hears it in *r* and *ir gn*, *sr* *ñ*, *pr* *nh*, in all of which LLB and E. hear (n) only
- (qjh) S4d, flated (qj), theoretical.
- (qh) S4a, C1x3, flated (q) B hears it before mutes, as *sink* (*siqhk*), E. does not, art. 11
- (qj) C14, palatalized (q), different from (qj)
- R (r rh rsh, r, r h, r r h, r, r h, r, r, R R, i)
- (r) C18, *r*, ring, tip of tongue far behind gums, flap weak in England, strong in Scotland and Italy
- (rh) C18, flated form of (r)
- (rsh) *rl prsz*, tongue in position for (sh) with point flapped
- (r) S5c, C18, imperfect (d), the tongue not quite in contact, almost (zh), imperfect (r), the flap being omitted, considered by B and Sw as normal (r), a sign for flapping being added where a trill is used. Sv makes *r* before a vowel regularly (*r*). To E., a born Londoner, (*r*) before a vowel is very difficult to utter
- (r h) S1c, flated (*r*), theoretical.
- (r) C19, *sr* *rey*, *ir* *re*, fully trilled *r* with the point of the tongue advanced to the gums.
- (rh) C19, flated (*r*), occ. *r nôt*
- (r) alveolar unflapped (*r*), see (*r*), possibly the "soft" *sr* *r* in *amar, arado, breve*
- (r) C13, Parisian Paris, uvular *r*, art. 10 (3), resembling (grh)
- (rh) C13, flated (*r*), common as a final *r* in the pause, and then greatly resembling a faint (hrh)
- (r) C12, labialized uvular (*r*), regular in Northumberland.
- (r) untrilled uvular (*r*), heard faintly between vowels in Northumberland, in *very, merry* (*va'r, i, ma'r, i*), almost (*va'i, in ai*), like *ir va'i, mai*
- (r) C17, reverted or cerebral *r*, the underpart of the point of the tongue brought near the palate, and, according to E. a observations, allowed to flap, but constantly asserted to be unflapped, see (*r*). Common in modern Indian, not in *sn*, and found in Norway and Sweden¹ The characteristic of south of England dialectal speech, and parent of received *r* and the vocal degeneration of *r*, art. 7 vii. By some considered as greatly retracted (*r*)
- (r) C17, unflapped variety of (*r*), supposed to prevail for (*r*), which see
- (r) art. 7 vii, fully degenerated vocal (*r*), which may be followed permissively by a trilled or flapped (*r*), forming the murmur diphthongs
- S (s sh shj sj, s, sh, s, sj)
- (s) S1c, C13, *s*, seal, hissing, with a convex tongue forming a central strait, the sides being held firmly by the palate and teeth, point tense and unruffled, with many unconscious varieties
- (sh) S1f, C13, *r*, *rush*, tongue retracted in respect to (s), upper surface rather hollowed than convex, see (sh, shj) and occ. lips projected, as *r* *linsh* (*linsh*)
- (shj) C13, (sh) with convex tongue, tip somewhat depressed,

second element in (*ty*=*tjshj*), High *o* *s* initial before *p, t*, as *spielcn, stehcn*, where (*sh*) is not admissible

- (s) C13, *rl* *kos*, palatalized (s), art. 12
- (s) C13, point of tongue advanced nearly to teeth LLB hears it in Tuscan sharp *ir lo zo*, usually taken as (*t, sio*)
- (sh) advanced (shj), tongue convex and nearer the palate LLB hears it in Tuscan *pece* (*pè, she*), and considers it the only proper sound of *ir* *c* before *e* and *i*, which is usually assumed to be (*t, sh*) or (*tj*), but an Englishman's (*tj*) is quite intelligible
- (s) AR. *ص* (*saad*), according to Lepsius a close emphatic *s* or (*s'*), see (K) and (*d, t, z*)
- (sj) Irish Gaelic *ciste* (*kj:stje*), treasure, *s* of the same series as (*tj*), which see [Lecky, MS communication.]
- T (t tj th tj, t, th, t, T, t, tj)
- (t) S3c, C18, *E too*, tip of the tongue far behind the gums, generated by reverted (*r*), with which it is confused by Indians, who use their cerebral *ṭ ṭ* for (*t, d*)
- (tj) *chest*=(*tjshj*), art. 12, not to be confounded with (*h j*), which see
- (th) S1d, C13, *E thin*, Icelandic *þ*, *mc* *θ*, AR *ث*, point of tongue against back of front teeth, hiss produced by flatus escaping between tongue and teeth, not necessarily between the interstices of the teeth, as Sw says
- (tj) C16, Hungarian *ty*, palatalized (*t*), art. 12, see (dj)
- (t) S3d, C19, *r tas*, usual Continental alveolar *t*, with the tongue against gums, *sn* *ṭ*, found in some midland and northern E dialects before *r* or *er*, see (d)
- (th) C13, *sr* *z* everywhere, and *c* before *e, i*, *vo: zo:po, ceceo onto, hisped* (*s*), tongue against gums, and hence a retracted (*th*), see (dh). LLB hears it in *ir vizio*, where it is generally assumed to be (*t, s*)
- (t) AR *ṭ* (*ṭaad*), which Lepsius describes as a close emphatic (*d'*), see (K)
- (r) C17, reverted or cerebral *s* *z*, with underpart of the point of the tongue against the palate, common in south-west *z* in connexion with (*r*), parent of received *z* (*t*)
- (rj) consonantal diphthong=(*rjh*), heard in Wiltshire in connexion with (*r*), as (*ai rj*) *rich*
- (t) Irish Gaelic "broad" post aspirated mute, as in Irish Gaelic *ait, tá, tí*. The place of the tip of the tongue is apparently unimportant, but it is generally assumed to be dental or interdental. The essential points are that the tongue is laterally expanded and slack, while the back is raised, leaving a hollow in the "front" It is followed by a slow flated glide, while the position changes to that of the vowel, resembling a greatly predominating (*th*) mixed with (*kh*) The voice is not put on till the vowel position is reached. This is constantly used for (*th*) by Irish speakers of English. [Lecky, MS communication.]
- (tj) Irish Gaelic "slender" form of post aspirated mute, as in *ait, of a knuckle*, the tongue is spreading and slack, the part nearest to the palate is about an inch on the inner side of the tip, being more towards the back than in the position for (*s*), the "front" being also raised, the tip is not turned up and its position is unimportant The glide of the post-aspiration sounds like a predominating (*jh*) mixed with (*s*), being tighter at first and looser afterwards than the *E* (*jh*) [Lecky, MS communication.]
- U (u ūa, u uh ūu, u, ū)
- (u) V3, T15, short *u* to unemphatic, *r poule*, replaced by (*u*) in *E, long E too* Some phonetists make the *E* long (*uu*) to be always (*ūu*) or (*uw*)
- (ūa) art. 7 vi, where (*ū*) replaces (*w*), *r* *oie* (*ūa*), *oia* (*ūu*), in *sei, deigi, &c.* LLB considers that (*s, d*), &c. are labialized, art. 12
- (u) V4, T14, *E full, wood, woman, could*, "wide" form of (*u*)
- (uh) V16 B hears it in the "colloquial" use of *E awful, fissure, nature, fortune* (which E. does not understand), but says also that it is (*u*) with a raised tongue, and hence=(*u'*) Sw hears it in *swd upp*, Sv and St in Norwegian *huaka*.
- (ūu) art. 7 ix, grave inchoant diphthong, possibly Sw's (*uw*), common dialectally in Cumberland and Westmorland.
- (u) midland *E* vowel replacing (*e, a*) E. feels it to be near (*o'*), or to be a "thickened" (*u*), Mr Hallam, to whom it is native, considers it to have the tongue intermediate to its position for (*o, u*), and the closure of the lips equal to that for (*o*), but made with flattened lips In Yorkshire, Cumberland, and Westmorland it is replaced by (*u*), with which most received speakers confound it.
- (v) V15 Sw hears it long in Norwegian and *swd hus, ut*, and says it is not far from *r lune*, but see (j) St² considers it intermediate between (*u, y*)

1662 he visited the universities of Basel, Tübingen, and Geneva, and commenced the study of heraldry, which he pursued throughout his life. In Geneva especially his religious views and tendencies were turned in the direction of his subsequent Pietism. He returned to Strasburg in 1663, where he was appointed preacher without pastoral duties, with the right of holding lectures in the university. Three years afterwards he was invited to become the chief pastor in the Lutheran church at Frankfort-on-the-Main. He had previously married a lady of his mother's choice, who made him an excellent wife and bore him eleven children. Immediately after his removal to Frankfort he commenced that line of pastoral work which issued in the movement called *Pietismus* (*yr*). In 1686 he accepted the invitation to the first court chaplaincy at Dresden. But the elector John George III, at whose personal desire the post had been offered to him, was soon offended at the fearless conscientiousness with which his chaplain sought to discharge his pastoral duties, and the opposition of the Saxon university of Leipzig to the Pietistic movement and to Spener personally served to render the chaplain more decidedly a *persona ingrata* to the elector. Spener refused to resign his post, and the Saxon Government hesitated to dismiss him. But in 1691 the Saxon representative at Berlin induced the court of Brandenburg to offer him the rectorship of St Nicolas in Berlin with the title of "consistorialrath." In Berlin Spener was held in high honour, though the tendencies of the court and the Government officials were rather rationalistic than pietistic. One of the most important works of this period of his life was the foundation of the university of Halle (1691), which he directed. All his life long Spener had been exposed to the incessant attacks and abuse of the orthodox Lutheran theologians, who generally charged him with the errors in doctrine and extravagances in practice of followers who had borrowed from him everything rather than his wisdom and caution. With his years his opponents multiplied, and the movement which he had inaugurated presented increasingly matter for hostile criticism. In 1695 the theological faculty of Wittenberg formally laid to his charge 264 errors, and only his death (5th February 1705) relieved him from these fierce conflicts.

Though Spener has been justly called "the father of Pietism," hardly any of the errors and none of the extravagances of the movement can be ascribed to him personally. So far was he from sharing them that Ritschl maintains (ii p. 163) that "he was himself not a Pietist," as he did not advocate the quietistic, legalistic, and semi separatist practices of Pietism, though they were more or less involved in the positions he assumed or the practices which he encouraged or committed. The only two points on which he departed from the orthodox Lutheran faith of his day were the requirement of regeneration as the *sine qua non* of the true theologian, and the expectation of the conversion of the Jews and the fall of Papacy as the prelude of the triumph of the church. He did not, like the later Pietists, insist on the necessity of a conscious crisis of conversion, nor did he encourage a complete breach between the Christian and the secular life.

Spener was a voluminous writer. The list of his published works comprises 7 vols folio, 63 quarto, 7 octavo, 46 duodecimo, and in one year he had answered 622 and had still to answer 300 letters. The most important of his works for their bearing on his history are *Theologische Bedenken*, in 4 parts, Halle, 1700-1703; *Letzte theologische Bedenken*, with a life of Spener by Causlein, Halle, 1711; *Concilia et iudicia theologica Latina* (posthumous), Frankfurt, 1709.

See Hossbach *Philipp Jakob Spener und seine Zeit* (Berlin 1828, 2d ed 1833 8d ed 1861) Tholuck in Herzog *Plut's Real Encyclopädie* (2d ed., vol. xiv), Gauss *Protestantische Dogmatik* (Berlin, 1857) Ritschl, *Gesch. des Pietismus* (i p. 97, ii (Witten 1884), and Bachse, *Ursprung und Wesen des Pietismus* (Wiesbaden, 1885).

SPENNYMOOR, a market town of Durham, England, is situated on the Ferryhill and Bishop Auckland branch of the North-Eastern Railway, $3\frac{1}{2}$ miles north-west of Ferryhill and 6 south of Durham by road. Within recent years it has increased with great rapidity owing to the production of coal and iron, and in 1865 it was formed into a market

town under a local board of health. It possesses a town hall, a mechanics' institute and reading room, and two market halls. A school board was formed in 1875. The population of the urban sanitary district (area 176 acres) in 1871 was 1627, and in 1881 it was 5917.

SPLINSLER, EDWARD (c. 1552-1599), Elizabethan poet, was born in London about the year 1552. The received date of his birth rests on a passage in sonnet lx of the *Amoretti*. He speaks there of having lived forty-one years, the *Amoretti* was published in 1595, and described on the title page as "written not long since." This would make the year of his birth 1552 or 1553. We know from the *Prothalamion* that London was his birthplace. This at least seems the most natural interpretation of the words—

"Merry London, my most kindly nurse,
That to me gave this life a first native source."

It would appear from a recent discovery by Mr B B Knowles that the relationship of the poet to the noble family of Spencer, if it existed at all—and official names such as Spencer (Dispenser) or Stewart (Steward) carry no proof of consanguinity—was remote, and that the poet's kinsmen must be sought among the humbler Spencers of north-east Lancashire. Robert Nowell a London citizen, left a sum of money to be distributed in various charities, and in the account-books of his executors Mr Knowles has discovered among the names of other beneficiaries "Edmund Spensere, scholar of the Merchant Taylor School, at his going to Pembroke Hall in Cambridge." The date of this benefaction is 28th April 1560. As the poet is known to have been a mazar of Pembroke the identification is beyond dispute. Till this discovery it was not known when Spenser received his school education. The speculations as to the poet's parentage started by the Nowell MS are naturally more uncertain. Mr Knowles found three Spencers in the books of the Merchant Taylors, and concluded that the poorest of them, John Spenser, a "free journeyman" in the "art or mystery of clothmaking" might have been the poet's father, but he afterwards abandoned this theory. Mr Grosart, however, adheres to it, and gives a confident solution of Mr Knowles's difficulties. Nothing approaching certainty can be reached on the point, which is not itself of much importance. The connection of Spenser with Lancashire is also supported by the Nowell MS. Several Spencers of that county appear among the "poor kinsfolk" who profited by Nowell's bounty.

It is natural that a poet so steeped in poetry as Spenser should show his faculty at a very early age, and there is strong reason to believe that verses from his pen were published just as he left school at the age of sixteen or seventeen. Certain pieces, translations from Du Bellay and Petrarch, afterwards included in a volume of poems by Spenser published in 1591, are found in a miscellany, *Theatre for Worldlings*, issued by a Flemish Protestant refugee, John van der Noodt, on the 25th of May 1560. The translations from Du Bellay appear in blank verse in the miscellany, and are rhymed in sonnet form in the later publication, but the diction is substantially the same, the translations from Petrarch are republished with slight variations. Poets were so careless of their rights in those days and publishers took such liberties that we cannot draw for certain the conclusion that would be inevitable if the facts were of more modern date, but the probabilities are that these passages in Van der Noodt's *Theatre*, although the editor makes no acknowledgment, were contributed by the schoolboy Spenser. As the exercises of a schoolboy writing before our poetic diction was enriched by the great Elizabethans, they are remarkable for a sustained command of expression which many schoolboys might ex-

habit in translation now, but which was a rarer and more significant accomplishment when Surrey and Sackville were the highest models in post-Chaucerian English.

Little is known of Spenser's Cambridge career, except that he was a sizar of Pembroke Hall, took his bachelor's degree in 1572, his master's in 1576, and left Cambridge without having obtained a fellowship. Mr Grosart's inquiries have elicited the fact that his health was not good,—college allowances while he was in residence being often paid "Spenser egrotanti." One of the fellows of Pembroke strongly influenced his destiny. This was Gabriel Harvey, a prominent figure in the university life of the time, an enthusiastic educationist, vigorous, versatile, not a little vain of his own culture and literary powers, which had gained him a certain standing in London society. The revival and advancement of English literature was a passion of the time, and Harvey was fully possessed by it. His fancy for reforming English verse by discarding rhyme and substituting unrhymed classical metres, and the tone of his controversy with Thomas Nash, have caused him to be regarded as merely an obstreperous and pragmatic pedant, but it is clear that Spenser, who had sense enough not to be led astray by his eccentricities, received active and generous help from him and probably not a little literary stimulus. Harvey's letters to Spenser¹ throw a very kindly light on his character.

Three years after leaving Cambridge, in 1579, Spenser issued his first volume of poetry, the *Shepherd's Calendar*. Where and how he spent the interval have formed subjects for elaborate speculation. That most of it was spent in the study of his art we may take for granted. That he lived for a time in the "north parts" of England, that there or elsewhere he fell in love with a lady whom he celebrates under the anagram of "Rosalind", that his friend Harvey urged him to return south, and introduced him to Sir Philip Sidney, that Sidney took to him, discussed poetry with him, introduced him at court, put him in the way of preferment,—are ascertained facts in his personal history. Mr Grosart conjectures with considerable plausibility that he was in Ireland in 1577 in the service of Sir Henry Sidney, Philip's father, and returned to England with that administrator in 1578.

The interest of the *Shepherd's Calendar* is mainly personal to Spenser. Its twelve poems continue to be read chiefly because they were the first published essays of the author of the *Fairy Queen*, the poems in which he tried and disciplined his powers. They mark no stage in the history of pastoral poetry. Spenser had too strong a genius not to make his own individuality felt in any form that he attempted, and his buoyant dexterity in handling various schemes of verse must always afford delight to the connoisseur in such things. But a reader not already interested in Spenser, or not already familiar with the artificial eclogue, would find little to attract him in the *Shepherd's Calendar*. The poems need a special education, given this, they are felt to be full of charm and power, a fresh and vivid spring to the splendid summer of the *Fairy Queen*. The diction is a studiously archaic artificial compound, partly Chaucerian, partly North Anglian, partly factitious, and the pastoral scenery is such as may be found in any country where there are sheep, hills, trees, shrubs, toadstools, and running streams. That Spenser, having been in the north of England, should have introduced here and there a touch of north country colour is natural enough, but it is not sufficient to give a character to the poems as pastoral poems. As such they follow continuously and do not violently break away from Latin, Italian, and French predecessors, and Mr George Saintsbury is undoubtedly right in indicating Marot as the most immediate model. At the same time one can quite understand on historical grounds why the *Shepherd's Calendar* was hailed with enthusiasm as the advent of a "new poet." Not only was it a complete work in a form then new to English literature, but the execution showed the hand of a master. There had been nothing so finished, so sustained, so masterful in grasp, so brilliant in metre and phrase, since Chaucer. It was felt at once that the poet for whom the age had been waiting had come. The little coterie of friends whose admiration the young poet had won in private were evidently concerned lest the wider

public should be bewildered and repelled by the unfamiliar pastoral form and rustic diction. To put the public at the right point of view the poems were published with a commentary by "E. K.,"—supposed to be one Edward Kike, who was an undergraduate with Spenser at Pembroke. This so-called "glosse" explained the archaic words, revealed the poet's intentions, and boasted that in the case of Virgil, the pastoral poetry of the "new poet" was but "a proving of the wings for higher and wider flights." The "new poet's" name was withheld, and the identification of the various "shepherds"—of Cuddie and Roffy and Diggon Davie, and the beauteous golden haired "widow's daughter of the glen"—was fortunately reserved to yield delight to the ingenious curiosity of a later age.²

The *Shepherd's Calendar* was published at Gabriel Harvey's instance, and was dedicated to Sir Philip Sidney. It was one out of many poetical schemes on which the young poet was busy in the flush of conscious power and high hopes excited by the admiration of the literary authorities whose approval was then most to be coveted. His letters to Harvey and Harvey's letters to him furnish hints for a very engaging fancy picture of Spenser at this stage of his life,—looking at the world through rose coloured spectacles, high in favour with Sidney and Leicester, dating his letters from Leicester House, gaily and energetically discussing the technicalities of his art, with some provision from his powerful friends—certain, but the form of it delightfully uncertain,—going to court in the train of Leicester, growing pointed beard and mustachios of fashionable shape, and frightening his ever vigilant friend and mentor Harvey by the light courtier like tone of his references to women. The studious pastoral poet from "north parts" had blossomed with surprising rapidity in the image of the gay fortune seeking adventurers who crowded the court of the virgin queen in those stirring times. Some of the poems which he mentions to Harvey as then completed or on the anvil—his *Dreams*, his *Nine Comedies*, his *Dying Pelican*, and his *Stemmata Dudleiana* (singing the praises of the noble family which was his friend's)—have not been preserved, at least in any form that can be certainly identified. He had sent Harvey a portion of the *Fairy Queen*, which he was eager to continue, but Harvey did not think much of it—a judgment for which Harvey is often ridiculed as a dull pedant, as if we knew for certain that what was submitted to him was identical with what was published ten years later.

Spenser was appointed secretary to the lord-deputy of Ireland in 1580, and was one of the band of adventurers who, with mixed motives of love of excitement, patriotism, piety, and hopes of forfeited estates, accompanied Lord Arthur Grey of Wilton to Ireland to aid in the suppression of Desmond's rebellion. Regret is sometimes expressed that the author of the *Fairy Queen*, who ought to have been dreamy, meditative, gentle, and refined, should have been found in such company, and should have taken part in the violent and bloody scenes of Lord Grey's two years' attempt at "pacification." But such things must be judged with reference to the circumstances and the spirit of the time, and it must be remembered that England was then engaged in a fierce struggle for existence against the Catholic powers of the Continent. Of Lord Grey's character his secretary was an enthusiastic admirer, exhibiting him in the *Fairy Queen* as Arleghal, the personification of justice, and we know exactly what were his own views of Irish policy, and how strongly he deplored that Lord Grey was not permitted to carry them out. Spenser's *View of the State of Ireland*, drawn up after fourteen years' experience, is not the work of a gentle dreamer, but of an energetic and shrewd public official.

The *View* is not a descriptive work, there is nothing in the style to indicate that it was written by a poet, it is an elaborate state paper, the exposition in the form of a dialogue of a minutely considered plan for the pacification of Ireland, written out of zeal for the public service for the eyes of the Government of the day. A very thoroughgoing plan it is. After passing in review the history and character of the Irish, their laws, customs, religion, habits of life, armour, dress, social institutions, and finding "evil usages" in every department, he propounds his plan of "reformation." Reformation can be effected only by the sword, by the strong hand. The interlocutor in the dialogue holds up his hands in horror. Does he propose extermination? By no means. But he would give the Irish a choice between submission and extermination. The Government had vacillated too long, and fearing the cost of a thorough operation, had spent twice as much without

¹ *Letter Book of Gabriel Harvey*, Camden Society.

² See Mr Grosart's *Complete Works of Spenser*, vol. I. XVII — 50

in any way mending matters. Let them send into Ireland 10,000 foot and 1000 horse, disperse them in garrisons—a complete scheme of localities is submitted,—give the Irish twenty days to come in, if they did not come in then, give no quarter afterwards, but hunt them down like wild beasts in the winter time when the covert is thin, “if they be well followed one winter, ye shall have little work to do with them the next summer”, famine would complete the work of the sword, and in eighteen months’ time peace would be restored and the ground cleared for plantation by English colonists. There must be no flinching in the execution of this plan,—“no remorse or drawing back for the sight of any such rueful object as must thereupon follow, nor for compassion of their calamities, seeing that by no other means it is possible to recover them, and that these are not of will but of very urgent necessity.” The Government had out of foolish compassion drawn back before when Lord Grey had brought the recalcitrant Irish to the necessary extremity of famine, the gentle poet warns them earnestly against a repetition of the blunder.

Such was Spenser’s plan for the pacification of Ireland, propounded not on his own authority, but as having support in “the consultations and actions of very wise governors and counsellors, whom he had sometimes heard treat thereof.” He knew that it was “bloody and cruel”, but he contended passionately that it was necessary for the maintenance of English power and the Protestant religion. Commentary on the plan, which has been so much and so warmly discussed, would be out of place here. The method was repugnant to the kindly nature of average Englishmen, from the time of Lord Grey no English authority had the heart to go through with it till another remorseless zealot appeared in the person of Cromwell. That Cromwell knew the treatise of “the sage and serious Spenser,” perhaps through Milton, is probable from the fact that the poet’s Irish estates were secured to his grandson by the Protector’s intervention in 1657. These estates had been granted to Spenser as his share in the redistribution of Munster,—3000 acres of land and Kileolman castle, an ancient seat of the Desmonds, in the north of the county of Cork. The elaborate and business-like character of the *View* shows that the poet was no sinecurist, but received his reward for substantial political services. He ceased to be secretary to the lord-deputy when Lord Grey was recalled in 1582, but he continued in the public service, and in 1586 was promoted to the onerous position of clerk to the council of Munster.

Amidst all the distractions of his public life in Ireland, Spenser seems to have proceeded steadily with the composition of the *Faery Queen*, translating his varied experience of men and affairs into the picturesque forms of his allegory, and expressing through them his conception of the immutable principles that ought to regulate human conduct. He had, as we have seen, conceived a work of the kind and made a beginning before he left England. The conception must have been very much deepened and widened and in every way enriched by his intimate daily contact with the actual struggle of conflicting individuals and interests and policies in a great crisis. Some four or five years later, being asked in a mixed company of English officials in Ireland (as recorded in Lodowick Bryskott’s *Discourse of Civil Life*) to give offhand a short sketch of “the ethical part of moral philosophy” and the practical uses of the study, Spenser explained to these simple-minded men that the subject was too intricate for an impromptu exposition, but that he had in hand a work called the *Faery Queen* in which an ethical system would be exhibited in action. The respect paid by his official brethren to Spenser as a man, “not only perfect in the Greek tongue, but also very well read in philosophy, both moral and natural,” is an interesting item in his biography. Some years later still, when Spenser was settled at Kileolman castle, Sir Walter Raleigh found him with three books of the *Faery Queen* completed, and urged him to go with them to London. London accordingly he re-

visited in 1589, after nine years’ absence. There is a very pretty record of this visit in *Colin Clout’s Come Hame Again*, published in 1595, but written in 1591, immediately after his return to Kileolman. The incidents of the visit, by that time matters of wistful memory, are imagined as a shepherd’s excursion from his quiet pastoral life into the great world. Colin Clout calls round him once again the masked figures of the *Shepherd’s Calendar*, and describes to them what he saw, how he fared, and whom he met at the court of Cynthia, and how through the influence of “the Shepherd of the Ocean” he was admitted at timely hours to play on his oaten pipe in the great queen’s presence.

How much is pure fiction and how much veiled fact in this picture cannot now be distinguished, but it is undoubted that Spenser, though his chief patrons, Leicester and Sidney were now dead, was very graciously received by the great world on his return to London. Not only did the queen grant him an audience, but many ladies of the court, several of whom he afterwards honoured with dedications, honoured him with their patronage. The first three books of the *Faery Queen*, which were entered at Stationers’ Hall on the 1st December 1589, were published in 1590, and he was proclaimed at once with remarkable unanimity by all the writers of the time as the first of living poets.

From the first work of its publication the literary world has continued unanimous about the *Faery Queen*, except on minor points. None of our great poets has been welcomed with such universal acclaim and upheld without loss of favour through change of fashion. When romanticism was at its lowest ebb Pope and Spenser in his old age with somewhat doubt as in his boyhood. He speaks himself of having had his detractors, of having suffered from the venomous tooth of the Blatant Beast, and he seems to have had in more than ordinary share the poet’s sensitivity to criticism. But the detractors or misapprehenders have generally been found among men who, like the lord high treasurer Purglish, have no liking for poetry of any kind. The secret of Spenser’s enduring popularity with poets and lovers of poetry lies specially in this that he excels in the poet’s peculiar gift, the instinct for verbal music. Shakespeare, or the author of the sonnet usually assigned to him, felt and expressed this when he drew the parallel between “music and sweet poetry.”—

“Thou lovest to hear the sweet melodious sound
That Phoebus lute doth give out of his golden bow,
And I in deep dell, hid among hilly drows,
Whenas I sing, I to him do bow.”

This is an early word in criticism of Spenser, and it is the last word about his prime and unquestionable excellence,—a word in which all critics must agree. Whether he had imagination in the highest degree or only luxuriant fancy, and whether he could tell a story in the highest epic manner or only put together a richly varied series of picturesque incidents, are disputable points, but about the enchantment of his verse there can be no difference of opinion. It matters not in the least that he gains his melody often by archaic affectations, licences of diction that should make Dr Richard Morris “stare and gasp”, there, however purchased the marvellously rich music is. In judging of the structure of the *Faery Queen* we must always remember that, long and diffuse as it is, what we have is but a fragment of the poet’s design, and that the narrative is regulated by an allegorical purpose, but, however intricate, however confused, the reader may feel the succession of incidents to be, when he studies the succession of incidents, it is only at the call of duty that he is likely to occupy himself with such a study in reading Spenser.

The ethical value of the allegory has been very variously estimated. The world would probably never have divined that there was any allegory if he had not himself drawn attention to it in a press dedication and in doggerel headings to the cantos. It was apparently at his friend Raleigh’s suggestion that the poet condescended to explain his ethical purpose, otherwise it would have been as problematical as the similar intention in the case of the *Idylls of the King* before that intention was expressly declared. It is almost to be regretted, as far as the allegory is concerned, that the friendly “E. R.” was not employed to furnish a “gloss” to the *Faery Queen* as he had done to the *Shepherd’s Calendar*. Undoubtedly the peculiar “poetic luxury” of the *Faery Queen* can be enjoyed without any reference to the allegory, even Professor Dowden, the most eloquent champion of Spenser’s claims as a “teacher,” admits that it is a mistake to look for minute correspondence between outward symbol and underlying sense, and that the poet is least enjoyable where he is most ingenious. Still the

allegory governs the structure of the poem, and Spenser himself attached great importance to it as determining his position among poets. The ethical purpose is distinctive of the poem as a whole, it was foremost in Spenser's mind when he conceived the scheme of the poem, and present with him as he built up and articulated the skeleton, it was in this respect that he claimed to have "overpassed" his avowed models Ariosto and Tasso. If we wish to get an idea of Spenser's imaginative force and abundance, or to see his creations as he saw them, we must not neglect the allegory. It is obvious from all that he says of his own work that in his eyes the ethical meaning not only heightened the interest of the marvellously rich pageant of heroes and heroines, enchanters and monsters, but was the one thing that redeemed it from romantic commonplace. For the right appreciation of many of the characters and incidents a knowledge of the allegory is indispensable. For example, the slaughter of Error by the Red Cross knight would be merely disgusting but for its symbolic character, the iron Talus and his iron flail is a revolting and brutally cruel monster if he is not regarded as an image of the executioner of righteous law, the Blatant Beast, a purely grotesque and ridiculous monster to outward view, acquires a serious interest when he is known to be an impersonation of malignant detraction.

After the publication of the *Faery Queen* Spenser seems to have remained in London for more than a year, to enjoy his triumph. It might be supposed, from what he makes the Shepherd of the Ocean say in urging Colin Clout to quit his banishment in Ireland, that Raleigh had encouraged him to expect some permanent provision in London. If he had any such hopes they were disappointed. The thrifty queen granted him a pension of £50, which was paid in February 1591, but nothing further was done for him. Colin Clout's explanation that the selfish scrambling and intriguing of court life were not suited to a lowly shepherd swain, and that he returned to country life with relief, may be pastoral convention, or it may have been an expression of the poet's real feelings on his return to Kileolman, although as a matter of fact there seems to have been as much scrambling for good things in Munster as in London. Certain it is that he did return to Kileolman in the course of the year 1591, having probably first arranged for the publication of *Daphnaida* and *Complaints*. *Daphnaida* is a pastoral elegy on the death of the niece of the mistress of the robes. The fact implied in the dedication that he was not personally known to the lady has more than once provoked the solemn remark that the poet's grief was assumed. Of course it was assumed, and it is hardly less obvious that sincerity of personal emotion, so far from being a merit in the artificial forms of pastoral poetry, the essence of which lies in its dreamy remoteness from real life, would be a blemish and a discord. Any suggestion of the poet's real personality breaks the charm, once raise the question of the poet's personal sincerity and the pastoral poem may at once be thrown aside. The remark applies to all Spenser's minor poetry, including his love-sonnets, the reader who raises the question whether Spenser really loved his mistress may have a talent for disputation but none for the full enjoyment of hyperbolic poetry. *Complaints*, also published in 1591, is a miscellaneous collection of poems written at different periods. The volume contained *The Ruins of Time*, *The Tears of the Muses*, *Virgil's Gnat*, *Mother Hubbard's Tale*, *The Ruins of Rome*, *Monopotmos*, *Visions of the World's Vanity*, *Bellay's Visions*, *Petrarch's Visions*. Some of these pieces are translations already alluded to and interesting only as the exercises of one of our greatest masters of melodious verse, but two of them, *The Tears of the Muses* and *Mother Hubbard's Tale*, have greater intrinsic interest. The first is the complaint of the decay of learning alluded to in *Midsummer Night's Dream*, v 1, 52—

"The three three Muses mourning for the death
Of Learning late deceased in beggary"

The lament, at a time when the Elizabethan drama was "mewing its mighty youth," was not so happy as some

of Spenser's political prophecies in his *View of Ireland*, but it is idle work to try to trace the undercurrents and personal allusions in such an occasional pamphlet. *Mother Hubbard's Tale*, a fable in Chaucerian couplets, shows a keenness of satiric force not to be paralleled in any other of Spenser's writings, and suggests that he left the court in a mood very different from Colin Clout's.

Spenser returned to London probably in 1595. He had married in the interval a lady whose Christian name was Elizabeth, —Mr Grosart says Elizabeth Boyle. The marriage, celebrated on the 11th of June 1594, was followed by a rapid succession of publications. The first was a volume (entered at Stationers' Hall, 19th November 1591, published 1595) containing the *Amoretti*, a series of exquisite sonnets commemorative of the moods and incidents of his courtship, and the magnificent *Epythalamion*, incomparably the finest of his minor poems. As in the case of the *Complaints*, the publisher for obvious reasons issued this volume nominally without his authority. *Colin Clout's Come Home Again* was published in the same year, with a dedication to Sir Walter Raleigh, dated 1591. Early in 1596 the second three books of the *Faery Queen* were entered in the register of Stationers' Hall, and in the course of the same year were published his *Four Hymns*, his *Prothalamion*, and his *Astrophel*, a pastoral lament for Sir Philip Sidney, which he dedicated to the countess of Essex.

That Spenser wrote more of the *Faery Queen* during the last two years of his life, and that the MS perished in the sack of Kileolman castle by the rebels, may plausibly be conjectured, but cannot be ascertained. During those years he would seem to have been largely occupied with political and personal cares. He describes himself in the *Prothalamion* as a disappointed suitor at court. He drew up his *View of Ireland* in 1596 when he was in London, and from various circumstances it is evident that he had hopes of some kind from the favour of Essex. The *View*, with its urgent entreaty that Essex should be sent to Ireland, was entered at Stationers' Hall in April 1598, but he did not obtain leave to publish it. Burghley, who had long stood in his way, died in August of that year, and next month Spenser was appointed sheriff of Cork. In October Tyrone's rebellion broke out, and Spenser's house was sacked and burned. The poet himself escaped, and in December was sent to London with despatches. Again he ventured to urge upon the queen his plan for the thorough "reformation" of Ireland. But his own end was near. On 16th January 1599 he died at Westminster, ruined in fortune, if not heart-broken, and was buried in Westminster Abbey, near his master Chaucer.

There have been many editions of Spenser's works. The most available and complete is the Globe edition, with a carefully edited text by Dr R. Morris, and a memoir by Professor J W Hales. Mr Grosart's edition, with its keenly argumentative biography and copious collection of variorum researches and critical opinions, is printed for private circulation. (W M)

SPERMACETI is a solid waxy body found in special cavities in the head of the sperm whale (*Physeter macrocephalus*), where it is held in solution by sperm oil while the creature is in life. At a temperature of about 6° C the solid matter separates in a crystalline condition, and when purified by pressure and treatment with weak solution of caustic alkali it forms brilliant white crystalline scales or plates, hard but unctuous to the touch, and destitute of taste or smell. It is quite insoluble in water, very slightly affected by boiling alcohol, but easily dissolved in ether, chloroform, and carbon bisulphide. Spermaceti consists principally of cetyl or cetyl palmitate, $C_{17}H_{35}O_2$, —an ether composed of cetyl alcohol combined with palmitic acid. Spermaceti candles of definite size are emulo

as a standard for illuminants on account of the uniform steady light they afford. The substance is further used in the dressing of fabrics and in medicine and surgery, especially in cerates, bougies, ointments, and in cosmetic preparations. For sperm oil, see WHALE OILS.

SPEUSIPPUS, son of Eurymedon and Potone, is supposed to have been born about 407 B.C. He was bred in the school of Isocrates, but, when his maternal uncle, Plato, returned to Athens about 387, he yielded to his influence and became a member of the Academy. In 361, when Plato undertook his third and last journey to Sicily, Speusippus accompanied him. In 347 the dying philosopher nominated his nephew to succeed him as scholarch, and the choice was ratified by the school. Speusippus held the office for eight years, and died in 339 after a paralytic seizure. According to some authorities he committed suicide. There is a story that his youth was riotous, until Plato's example led him to reform his ways. In later life he was conspicuously temperate and amiable. He was succeeded by Xenocrates.

Of Speusippus's many philosophical writings nothing survives except a fragment of a treatise *On Pythagorean Numbers*. Nor have secondary authorities preserved to us any general statement or conspectus of his system. Incidentally, however, we learn the following details. (A) In regard to his theory of being,—(1) whereas Plato postulated as the basis of his system a cause which should be at once Unity, Good, and Mind, Speusippus distinguished Unity, the origin of things, from Good, their end, and both Unity and Good from controlling Mind or Reason, (2) whereas Plato recognized three kinds of numbers—firstly, ideal numbers, the formal causes of the ideas, secondly, mathematical numbers, the abstractions of mathematics, and thirdly, sensible numbers, numbers embodied in things—Speusippus rejected the ideal numbers, and consequently the ideas, (3) Speusippus traced number, magnitude, and soul each to a distinct principle of its own. (B) In regard to his theory of knowledge,—(4) he held that a thing cannot be known apart from the knowledge of all things besides, for, that we may know what a thing is, we must know how it differs from other things, which other things must therefore be known, (5) accordingly, in the ten books of a work called *Ὅμοια*, he attempted a classification of plants and animals, (6) the results thus obtained he distinguished at once from "knowledge" (*ἐπιστήμη*) and from "sensation" (*αἴσθησις*), holding that "scientific observation" (*ἐπιστημονικὴ αἴσθησις*), though it cannot attain to truth, may nevertheless, in virtue of a certain acquired tact, frame "definitions" (*λόγοι*). (C) In regard to his theory of ethics,—(7) he denied that pleasure was a good, but seemingly was not prepared to account it an evil.

In default of direct evidence, it remains for us to compare these scattered notices of Speusippus's teaching with what we know of its original, the teaching of Plato, in the hope of obtaining at least a general notion, firstly, of Speusippus's system, and, secondly, of its relations to the systems of Plato, of contemporary Platonists, such as Aristotle, and of the later Academy.

It has been suggested elsewhere (*SOCRATES*, p. 238 *supra*) that the crude and unqualified "realism" of Plato's early manhood gave place in his later years to a theory of natural kinds founded upon a "thoroughgoing idealism," and that in this way he was led to recognize and to value the classificatory sciences of zoology and botany. More exactly, it may be said that the Platonism of Plato's maturity included the following principal doctrines—(1) the supreme cause of all existence is the One, the Good, Mind, which evolves itself as the universe under certain eternal immutable forms called "ideas", (2) the ideas are apprehended by

finite minds as particulars in space and time, and are then called "things", (3) consequently the particulars which have in a given idea at once their origin, their being, and their perfection may be regarded, for the purposes of scientific study, as members of a natural kind, (4) the finite mind, though it cannot directly apprehend the idea, may, by the study of the particulars in which the idea is revealed, attain to an approximate notion of it.

Now when Speusippus (1) discriminated the One, the Good, and Mind, (2) denied the ideas, and (3) abandoned the attempt to unify the plurality of things, he explicitly rejected the theory of being expressed in (1) and (2), and the rejection of the theory of being, *et c.*, of the conception of the One evolving itself as a plurality of ideas, entailed consequential modifications in the theory of knowledge conveyed in (3) and (4). For, if the members of a natural kind had no common idea to unite them, scientific research, having nothing objective in view, could at best afford a *lógos* or definition of the appropriate particulars, and, as the discrimination of the One and the Good implied the progression of particulars towards perfection, such a *lógos* or definition could have only a temporary value. Hence, though, like Plato, Speusippus (4) studied the differences of natural products (5) with a view to classification, he did not agree with Plato in his conception of the significance of the results thus obtained, that is to say, while to Plato the definition derived from the study of the particulars included in a natural kind was an approximate definition of the idea in which the natural kind originated, to Speusippus the definition was a definition of the particulars studied, and, strictly speaking, of nothing else. Thus, while Plato hoped to ascend through classificatory science to the knowledge of eternal and immutable laws of thought and being, Speusippus, abandoning ontological speculation, was content to regard classificatory science not as a means but as an end, and (6) to rest in the results of scientific observation. In a word, Speusippus turned from philosophy to science.

It may seem strange that, differing thus widely from his master, Speusippus should have regarded himself and should have been regarded by others as a Platonist, and still more strange that Plato should have chosen him to be his successor. It is to be observed, however, firstly, that the scientific element occupied a larger place in Plato's later system than is generally supposed,¹ and, secondly, that the only Academics who came into competition with Speusippus agreed with him in his rejection of the theory of ideas. Hence Plato, finding in the school no capable representative of his ontological theory, might well choose to succeed him a favourite pupil whose scientific enthusiasm and attainment were beyond question, and Speusippus's rivals, having themselves abandoned the theory of ideas, would not be in a position to tax him with his philosophical apostasy.

In abandoning the theory of ideas—that is to say, the theory of figures and numbers, the possessions of universal mind, eternally existent out of space and time, which figures and numbers when they pass into space and time as the heritage of finite minds are regarded as things—Speusippus had the approval, as of the Platonists generally, so also of Aristotle. But, whereas the new scholarch, confining himself to the detailed examination of natural kinds, attempted no comprehensive explanation of the universe, Aristotle held that a theory of its origin, its motions,

¹ That Plato did not neglect, but rather encouraged, classificatory science is shown, not only by a well known fragment of the comic poet Epicrates which describes a party of Academics engaged in investigating, under the eye of Plato, the affinities of the common pumpkin, but also by the *Timæus*, which, while it carefully discriminates science from ontology, plainly recognizes the importance of the study of natural kinds.

and its order was a necessary adjunct to the classificatory sciences, and in nearly all his references to Speusippus he insists upon this fundamental difference of procedure. Conceiving that the motions of the universe and its parts are due to the desire which it and they feel towards the supreme external mind, so that the cosmical order is initial in the divine mind, final in the phenomenal universe, Aristotle supposes himself thus to secure the requisite unification of the variety of things. Contrariwise, when Speusippus distinguishes One, Good, and Mind, so that Mind, not as yet endowed with an orderly scheme, adapts the initial One to a variety of particular Goods, his theory of nature appears to his rival "episodical," i.e., to consist of a series of tableaux wanting in dramatic unity, so that it reminds him of Homer's line—*οὐκ ἀγαθὸν πολυλοκιστὴν εἶς κοίρανος ἔστω*. The theory propounded by Aristotle himself is not perhaps impeccable in this respect, but at any rate he does not, like Speusippus, despair of a solution of the traditional problem of the One and the Many.

Speusippus and his contemporaries in the school exercised an important and far reaching influence upon Academic doctrine. When they, the immediate successors of Plato, rejected their master's ontology and proposed to themselves as ends mere classificatory sciences which with him had been means, they bartered their hope of philosophic certainty for the tentative and provisional results of scientific experience. Xenocrates indeed, identifying ideal and mathematical numbers, sought to shelter himself under the authority of Plato, but, as the Xenocratean numbers, though professedly ideal as well as mathematical, were in fact mathematical only, this return to the Platonic terminology was no more than an empty form. It would seem, then, that Academic scepticism began with those who had been reared by Plato himself, having its origin in their acceptance of the scientific element of his teaching apart from the ontology which had been its basis. In this way, and, so far as the present writer can see, in this way only, it is possible to understand the extraordinary revolution which converted Platonism, philosophical and dogmatic, into Academicism, scientific and sceptical. It is as the official representative of this scientific and sceptical departure that Speusippus is entitled to a place in the history of philosophy.

SPEY, a river in the north of Scotland, rises in the south-east of Inverness-shire from a small tarn called Loch Spey, 5 miles east of the Caledonian Canal, and flows north-eastwards by Kingussie to Grantown in Elginshire, 10 miles below which it reaches Banffshire. After forming for about 15 miles the boundary between Elginshire and Banffshire, it again enters the former county, through which it flows for about 10 miles past Fochabers to the Moray Firth. In the earlier part of its course it is fed by a large number of mountain streams, its principal tributaries being, in Inverness-shire, the Tromie and the Feshie from the right and the Dulnain from the left, and on the boundaries of Banff and Elgin the Avon (Aven) and the Fiddich from the right. Its entire length is 96 miles, and it drains an area of about 1200 square miles. The flow of the river is very rapid, and, being fed largely by mountain streams, it is subject to sudden freshets, which sometimes occasion extensive floods, the greatest being that of 1829. The Spey is, next to the Tay and the Tweed, the most important salmon river in Scotland. The scenery in its upper courses is occasionally bare and bleak, but sometimes finely picturesque, especially where, as in Elginshire

and Banffshire, its bold and rocky banks are clothed by forests of birch and pine.

See L. Shaw, *History of the Province of Moray* (1st ed. 1775, 3d ed. 1882), and Sir Thomas Dick Lauder, *Account of the Moray Floods* (1st ed. 1830, 4th ed. 1873).

SPEZIA, a city of Italy, in the province of Genoa, 56 miles south-east of Genoa by the railway to Pisa, which has become since the unification of the kingdom one of the principal Italian ports and the seat of a great Government arsenal. It is situated at the north-west angle of the Gulf of Spezia, formerly known as Lunæ Portus, the western side of which is formed by a rocky promontory about 4 miles long, terminating in the picturesque little town of Portovenere and the islands of Palmaria and Tino. A great breakwater, constructed about 1860, stretches across the gulf from Santa Maria Point to Santa Teresa Point for a distance of 7220 feet, and the outer harbour to the south-west of the town, excavated in 1865 to a depth of 32 feet, has an area of 247 acres. The arsenal has a length of 3937 feet and an average breadth of 2460 feet. The first dock covers an area of 20 acres and the second 17 acres, and there are besides two carpening basins, 433 and 354 feet long. Farther south lie the extensive military establishments of San Vito, with storerooms, reservoir, &c., and almost right opposite, on the other side of the gulf, are the dock (1½ acres), shipbuilding yards, and repairing docks of San Bartolomeo. Some of the largest vessels of the Italian navy have been constructed at Spezia. As a commercial centre Spezia suffers from the lack of railway communication with the interior,—the range of the Apennines lying between it and the more productive regions of Northern Italy. The whole movement of the port in 1884 was represented by 38 vessels engaged in foreign trade (tonnage, 29,251) and 1333 engaged in the coasting trade (tonnage, 198,447). Though the town itself, with the barracks and military hospital as its principal buildings, presents little to attract the foreign visitor, the beauty of the gulf and of the neighbouring country has brought Spezia into some repute as a watering-place, and there are several excellent hotels in the Corso. The walls and gates of the old city are for the most part destroyed. In one of the public squares is a statue of Admiral Chiudo, the founder of the arsenal. The population of the city was 6105 in 1861 (commune 11,556) and 19,864 in 1881 (commune 30,732).

The origin of Spezia is doubtful, but it probably rose after the destruction of Luna. Sold by one of the Fieschi in 1276 to Genoa, the town was fortified by its new possessors and made the seat of a governor of some importance. It became a city in the 16th century. The idea of making the Gulf of Spezia a great naval centre was first broached by Napoleon I.

SPHEROMETER, an instrument for the precise measurement of the radius of a sphere or the thickness of a thin plate. The usual form consists of a fine screw moving in a nut carried on the centre of a small three-legged table. The lower end of the screw and those of the table legs are finely tapered and terminate in hemispheres, so that each rests on a point. If the screw has two turns of the thread to the millimetre, the head is usually divided into 500 equal parts, so that differences of 0.001 millimetre may be measured without using a vernier. A vertical scale fastened to the table indicates the number of whole turns of the screw and serves as a fixed point for reading the divisions on the head. In order to measure the thickness of a plate the instrument is placed on a level plane surface and the screw turned until the point just touches, the exact instant when it does so is defined by a sudden diminution of resistance succeeded by a considerable increase. The divided head and scale are read, the screw is raised, the thin plate slipped under it, and the process is repeated. The difference between the two readings gives

the required thickness. A contact-level, delicate level, or other contact arrangement may be attached to the spherometer in order to indicate the moment of touching more precisely than is possible by the sense of touch. To measure the radius of a sphere— r , the curvature of a lens—the spherometer is levelled and read, then placed on the sphere adjusted until the four points exert equal pressure, and read again. The difference gives the thickness of that part of the sphere cut off by a plane passing through the three feet and, since the feet are equidistant, this distance (h) being known gives the value (R) of the radius from the formula $2R = \frac{r^2}{3h} + h$, where h is the thickness of

the lenticular segment. The *U spherometer*¹ is adapted for measuring small spherical lenses. The true plane on which the instrument stands is perforated by a cylindrical well of known diameter. A plate applied to the lower edge of the well by a spring is adjusted to be parallel to the base plane, and the spherometer screw, being centred over the well, is run down until it touches the plate, and then read. The plate is removed, the lens put in its place, the point—well accurately centred—is brought down and the screw is read again. The difference between the two readings gives the height of the section of the lens above the lower edge of the well. Calling this height h and the radius of the cylindrical well r , the radius R of

the sphere is got by the formula $2R = \frac{r^2}{h} + h$. The spherometer can be applied to test the sphericity of a globe, and may be used on either a convex or a concave surface.

SPHINX, a hybrid creature of Egyptian and Greek art and mythology. In Egypt the sphinxes are colossal images of granite or porphyry, with a human head and breast and the body of a lion (wingless) lying down. The largest and most famous is that of Gizeh, described in vol. vii p. 772. The head of the sphinx is usually that of a man, but ram's heads are said to occur occasionally. From Egypt the figure of the sphinx passed to Assyria, where it appears with a bearded male head on cylinders, the female sphinx, lying down and furnished with wings, is first found in the palace of Esarhaddon (7th century B.C.). Sphinxes have been found in Phoenicia, one at least being winged and another bearded. In Asia Minor an ancient female sphinx, but wingless, stands on the sacred road near Miletus. Sphinxes of the usual Greek type (female heads with bodies of winged lions) are represented seated on each side of two doorways in an ancient frieze found by Sir Charles Clibborn at Xanthus in Lycia, and now in the British Museum. The same type appears on the early reliefs of the temple at Assos. In the early art of Cyprus—that half-way house between Asia and Greece—sphinxes of this type are not uncommon. On the other hand, on a gem of Phoenician style found at Curium in Cyprus there appear two male (bearded) sphinxes, with the face of life between them. With regard to Greece the first third of the sphinx on the acropolis of Mycenae were

In Greek mythology the most famous sphinx was that of Thebes in Boeotia. She is first mentioned by Hesiod (*Theog.*, 326), who calls her the daughter of Orthus and Chimera. According to Apollonius (iii 3, 8), she was the daughter of Typhon and Echidna, and had the face of a woman, the feet and tail of a lion, and the wings of a bird. She dwelt on a bald rocky mountain at the south-east corner of the Copais lake, the name of the mountain was Phicium (now Fagas), which was derived from Phix, the Aeolic form of sphinx. The Muses taught her a riddle and the Thebans had to guess it. Whenever they failed she carried one of them off and devoured him. The riddle was this: What is that which is four-footed, three-footed, and two-footed? At last Oedipus guessed correctly that it was man, for the child crawls on hands and feet, the adult walks upright, and the old man supports his steps with a stick. Then the sphinx threw herself down from the mountain.

The story of the sphinx's riddle first occurs in the Greek tragedians. Milchhofer believes that the story was a mere invention of Greek fancy, an attempt to interpret the mysterious figure which Greek art had borrowed from the East. On the other hand, he holds that the destroying nature of the sphinx was much older, and he refers to instances in both Egyptian and Greek art where a sphinx is seen seizing and standing upon a man. And, whereas the Theban legend is but sparingly illustrated in Greek art, the figure of the sphinx appears more commonly on tombs, sculptured either in the round or in relief. From this Milchhofer seems to infer that the sphinx was a symbol of death. The word 'sphinx' is Greek, being derived from *σφιγγω*, "to draw tight."

SPIKENARD, or **NARD** (Hebrew *nard*, Gr *ιάρδος*, from Sanskrit *naladivatha*, the change from "r" to "l" seeming to indicate that the word came through Persia),² a celebrated perfume which seems to have formed one of the most durable aromatic ingredients in the costly unguents used by the Romans and Eastern nations. The ointment prepared from it ("ointment of pistie nard"³) is mentioned in the New Testament (Mark xiv 3-5, John xii 3-5) as being "very costly," a pound of it being valued at more than 300 denarii (over £10). This appears to represent the prices then current for the best quality of nard, since Pliny (*H.N.*, xii 26) mentions that nard spikes reached as much as 100 denarii per lb, and, although he does not mention the price of nard ointment, he states (xiii 2) that the "unguentum cinnamomum," a similar preparation, ranged from 25 to 300 denarii according to its quality. Nard ointment also varied considerably in price from its liability to sophistication (Id., xii 26, 27, xiii 2). The ingredients of the genuine ointment (*unguentum nardinum sine solvato*), Pliny tells us (xiii 2), were Indian nard, junceus (the leaves of *Andropogon Schenanthus*, L.), costus (the root of *Aplotaris auriculata*, DC.), amomum (the fruits of *Amomum Cardamomum*, L.), myrrh (the gum resin of *Balsamodendron Myrrha*, Nees), balm (the oleo-resin of *Balsamodendron Opobalsamum*), omphacium or oleum omphacium (the oil expressed from unripe olives), and balaninum (derived from *Balanites aegyptiaca*). Dioscorides (i 75) also remarks that malabathrum (the leaf of *Cinnamomum Tanaka*, Nees) was sometimes added. Of these ingredients costus and amomum were most relied upon for increasing the fragrance and the nard for the stimulating and other virtues of the unguent.⁴

² See Fick in *On the Origin of Words*, iii p. 361. The Syrians and Arabs may call it "nar" (*al-shar*, *al-shil*) or "the Indian spike."

³ The meaning of the word "pistie" is uncertain, some rendering it "pistie" (*pistie*) and others taking it for a local name.

⁴ The use of malabathrum is said for preserving these fragrant unguents.

The exact botanical source of the true or Indian nard was long a matter of uncertainty, the descriptions given by ancient authors being somewhat vague. Theophrastus (*De Odoi*, 28) classes nard amongst roots, and states that it came from India (*Hist. Plant.*, ix 7, 2), had a biting and hot taste, and resembled iris root in perfuming the air near it (*De Odoi*, 12, 56). He also remarks (*l.c.*, 42) that the ointment was one of the most durable of perfumes. Pliny (*H.N.*, vii 26, 27) gives a somewhat confused account, from which it appears that both "spike" and leaf were in use, although it is not clear whether the spike (*spica*) consisted of the flower-head or the fibrous lower portion of the stem. The only definite statement he makes concerning it is that the "sincere" nard is known by its red colour, sweet smell, and especially taste, "for it drieth the tongue and leaveth a pleasant relish behind it." Dioscorides (i 6) states that the true nard came from India and was collected on mountains beside which the river Ganges flowed. He describes it as blackish with short spikes, smelling something like cyperus. Linnæus, Blane, Hatchett, and other writers have supposed that spikenard was an Indian grass of the genus *Andropogon* (*A. Nardus*, L.), but Sir W. Jones (*As Res.*, ii 416, iv 97) has given convincing reasons for identifying it with *Nardostachys Jatamansi*,¹ a plant of the Valerian order, the fibrous root-stocks or "spikes" of which are still collected in the mountains of Bhutan and Nepal. Further evidence is afforded by Lambert (*Illustr. of the Genus Cinchona*, App., p. 177), who found the root under the name of "spikenard" in one of the oldest chemist's shops in London, also by Dymock (*Mat. Med. W. India*, 2d ed., p. 347), who states that the principal use of the drug at the present time is for making hair washes and ointments, the popular opinion being that it promotes the growth and blackness of the hair. The name of "spike" applied to the Indian nard appears to be derived from its resemblance in shape to a spike or ear of bearded corn. The root is crowned by the bases of several stems, each about 2 inches or more in length and as thick as the finger. To these the fibrous tissue of former leaves adheres and gives them a peculiar bristly appearance. It is this portion that is chiefly collected.

Other and inferior varieties of nard are mentioned by Dioscorides and subsequent writers. Celtic nard, obtained from the Ligurian Alps and Istria, consisted of the roots of plants also belonging to the Valerian order (*Valeriana cellica* and *V. salicina*). This was exported to the East and thence to Egypt, and was used in the preparation of baths. Mountain nard was collected in China and Syria, and is supposed to have consisted of the root of *Valeriana tuberosa*. The false nard of Dauphiné, used in later times, and still employed as a charm in Switzerland, is the root stock of *Althum Pictorialis*. It presents a singular resemblance to the spikes of Indian nard, but is devoid of fragrance. It is remarkable that all the nards belong to the natural order *Valerianaceae*, the odour of Valerian being considered disagreeable at the present day, that of *Nardostachys Jatamansi* is intermediate between Valerian and patchouli, although more agreeable than either.

The name "spikenard" has also been applied in later times to several plants. The spikenard of the United States is *Aralia racemosa*, and another species of the same genus, *A. nudicaulis*, is known as "false spikenard." In the West Indies *Huphis suaveolens* is called "spikenard," and in Great Britain the name "ploughman's spikenard" is given to *Inula Conyza*. (E. M. H.)

was customary at a very early period. Theophrastus (c. 314 B.C.) states that vessels of lead and alabaster were best for the purpose, on account of their density and coolness, and their power of resisting the penetration of the ointment into their substance. Pliny also recommends alabaster for ointment vessels. For small quantities only vessels seem to have been used (Horne, *Carm.* iv, 12, li 10, 17).

¹ The plant figured by Sir W. Jones is *Valeriana Hardwickii* (probably the inferior Gangetic nard of Dioscorides and the ozonitis of Pliny), the true plant is figured by Royle and Lambert.

SPINEL See MINERALOGY, vol vii p. 386, and RUBY.

SPINELLO ARETINO (c. 1330-c. 1410), painter, the son of a Florentine named Luca, who had taken refuge in Arezzo in 1310 when exiled with the rest of the Ghibelline party, was born at Arezzo about 1330. Spinello was a pupil of Jacopo di Casentino, a follower of Giotto, and his own style was a sort of link between the school of Giotto and that of Siena. In the early part of his life he worked in Florence as an assistant to his master Jacopo while painting frescoes in the church of the Carmine and in Sta. Maria Novella. Between 1360 and 1384 he was occupied in painting many frescoes in and near Arezzo, almost all of which have now perished.² After the sack of Arezzo in 1384 Spinello returned to Florence, and in 1387-88 with some assistants covered the walls and vault of the sacristy of S. Miniato near Florence with a series of frescoes, the chief of which represent scenes from the life of St. Benedict. These still exist, though in a sadly restored condition, they are very Giotto-like in composition, but have some of the Siena decorative brilliance of colour. In 1391-92 Spinello was painting six frescoes, which still remain on the south wall of the Pisan Campo Santo, representing miracles of St. Potitus and St. Ephesus. For these he received 270 gold florins. Among his later works the chief are the very fine series of frescoes painted in 1407-8 on the walls and vault of a chapel in the municipal buildings of Siena, these also have suffered much from repainting, but still are the finest of Spinello's existing frescoes. Sixteen of these represent the war of Frederick Barbarossa against the republic of Venice. Spinello died at Arezzo about 1410.

Spinello's frescoes are all strong and highly decorative works, drawn with much spirit, and are very superior in style to his panel pictures, many of which appear to be mere *bottega* productions. The academy of Florence possesses a panel of the Madonna and Saints, which is chiefly interesting for its signature—"Ille opus pinxit Spinellus Luce Artie D. I. A. 1391." The panel pictures which are to be found in the various galleries of Europe give little or no notion of Spinello's power as a painter.

SPINNING See YARN.

SPINOLA, AMBROCIO SPINOLA, MARCHESE DI (c. 1571-1630), a celebrated general, belonged to a noble and wealthy Italian family, and was born at Genoa about 1571. After the siege of Ostend had languished for more than two years under the direction of the archduke Albert, Spinola, who, though not a soldier by profession, had seen something of campaigning during a season or two, came upon the scene as a condottiere and received charge of the works. He entered upon his task in October 1603, and his courage and vigour were rewarded by the surrender of the place on 20th September 1604. During the next five years, until the conclusion of the armistice of 1609, he frequently encountered Maurice of Orange, but on the whole with undecisive results. In 1620 he was sent by Spain into the Palatinate of the Rhine, and took many places, in the following year, on the renewal of the war with Holland, he returned to the scenes of his earlier campaigns, where his principal exploits were the capture of Julich in February 1622 and of Breda after a ten months' siege in June 1625. His health now began to give way, and his spirits are said to have been further depressed by Philip's disregard of his pecuniary claims. He died at Castel-Nuovo di Servia on 25th September 1630.

SPINOZA, BARUCH (1632-1677), or, as he afterwards signed himself, Benedict de Spinoza, philosopher, was born at Amsterdam on 24th November 1632. His parents he

² The fine fresco of an Apocalyptic scene which still exists in S. Maria a gli Angeli at Arezzo belongs to about 1400.

longed to the community of Jewish emigrants from Portugal and Spain who, fleeing from Catholic persecution in the Peninsula, had sought refuge in the nearly emancipated Netherlands. The name, variously written De Spinoza, D'Espinoza, and Despinoza, probably points to the province of Leon as the previous home of the family, there are no fewer than five townships so called in the neighbourhood of Burgos. Of the philosopher's parents nothing is known. His father is said to have been a tradesman in fair circumstances, and the house is still shown upon the Burgwal where his son Baruch was born, two sisters, Rebekah and Miriam, formed the remainder of the family. Spinoza received his first training under the senior rabbi, Sanl Levi Morteira, whose most promising pupil he soon became. Under Morteira he became familiar with the Talmud and, what was probably more important for his own development, with the philosophical writings of Ibn Ezra and Maimonides, Levi ben Gerson, Chasdai Creskas, and other representatives of Jewish mediæval thought, who aim at combining the traditional theology with ideas got from Aristotle and his Neoplatonic commentators. Latin, still the universal language of learning, formed no part of Jewish education, and Spinoza, after learning the elements from a German master, resorted for further instruction to a physician named Franz van den Ende, who eked out an income by taking pupils. Van den Ende appears to have been distinctly a man of parts, though of a somewhat indiscreet and erratic character. He was eventually hanged in Paris as a conspirator in 1674. His enthusiasm for the natural sciences may have been the only ground for the reputation he had acquired of instilling atheistic notions into the minds of his pupils along with the Latin which he taught them. But it is quite possible that his scientific studies had bred in him, as in many others at that time, a materialistic, or at least a naturalistic, turn of mind, indeed we should expect as much in a man of Van den Ende's somewhat rebellious temperament. We do not know whether his influence was brought to bear in this sense upon Spinoza, but it has been suggested that the writings of Bruno, whose spirit of enthusiastic naturalism and fervid revolt against the church would be especially dear to a man of Van den Ende's leanings, may have been put into the pupil's hand by the master. Latin, at all events, Spinoza learned from Van den Ende to use with correctness, freedom, and force, though his language does not, of course, conform to classical canons. The only romance of Spinoza's life is connected with Van den Ende's household. The physician had an only daughter, Clara Maria by name, who, besides being a proficient in music, understood Latin, it is said, so perfectly that she was able to teach her father's pupils in his absence. Spinoza, the story goes, fell in love with his fair instructress, but a fellow-student, called Kerkring, supplanted him in his mistress's affections by the help of a valuable necklace of pearls which he presented to the young lady. Chronology unfortunately forbids us to accept this little episode as true. Recent investigation has proved that, while the marriage with Kerkring, or rather Kerckrink, is a fact, it did not take place till 1671, in which year the bride, as appears by the register, was twenty-seven years of age. She cannot, therefore, have been more than eleven or twelve in 1656, the year in which Spinoza left Amsterdam, and as Kerckrink was seven years younger than Spinoza, they cannot well have been simultaneous pupils of Van den Ende and simultaneous suitors for his daughter's hand. But, though the details of the story thus fall to pieces, it is still possible that in the five years which followed his retirement from Amsterdam Spinoza, who was living within easy distance and paid visits to the city from time to time, may have kept up his connexion with Van den

Ende, and that the attachment may have dated from this later period. This would at least be some explanation for the existence of the story, for Colerus expressly says that Spinoza "often confessed that he meant to marry her." But beyond possibility we cannot go in the matter. There is no mention of the Van den Endes in Spinoza's correspondence, and in the whole tenor of his life and character there is nothing on which to fasten the probability of a romantic attachment.

The mastery of Latin which he acquired from Van den Ende opened up to Spinoza the whole world of modern philosophy and science, both represented at that time by the writings of Descartes. He read him greedily, says Colerus, and afterwards often declared that he had all his philosophical knowledge from him. The impulse towards natural science which he had received from Van den Ende would be strengthened by the reading of Descartes, he gave over divinity, we are told, to devote himself entirely to these new studies. His inward break with Jewish orthodoxy dated, no doubt, farther back,—from his acquaintance with the philosophical theologians and commentators of the Middle Ages, but these new interests combined to estrange him still further from the traditions of the synagogue. He was seldom seen at its services,—soon not at all. The jealousy of the heads of the synagogue was easily roused. An attempt seems to have been made to draw from him his real opinions on certain prominent points of divinity. Two so-called friends endeavoured, on the plea of doubts of their own, to lead him into a theological discussion, and, some of Spinoza's expressions being repeated to the Jewish authorities, he was summoned to give an account of himself. Anxious to retain so promising an adherent, and probably desirous at the same time to avoid public scandal, the chiefs of the community offered him a yearly pension of 1000 florins if he would outwardly conform and appear now and then in the synagogue. But such deliberate hypocrisy was abhorrent to Spinoza's nature. Threats were equally unavailing, and accordingly on the 27th of July 1656 Spinoza was solemnly cut off from the commonwealth of Israel. The curses pronounced against him may be read in most of the biographies. While negotiations were still pending, he had been set upon one evening by a fanatical ruffian, who thought to expedite matters with the dagger. Warned by this that Amsterdam was hardly a safe place of residence for him any longer, Spinoza had already left the city before the sentence of excommunication was pronounced. He did not go far, but took up his abode with a friend who lived some miles out on the Old Church road. His host belonged to the Collegiants or Rhynsburgers, a religious society which had sprung up among the proscribed Arminians of Holland. The pure morality and simple minded piety of this community seem early to have attracted Spinoza, and to have won his unfeigned respect. Several of his friends were Collegiants, or belonged to the similarly-minded community of the Mennonites, in which the Collegiants were afterwards merged. In this quiet retreat Spinoza spent nearly five years. He drew up a protest against the decree of excommunication, but otherwise it left him unmoved. From this time forward he disused his Hebrew name of Baruch, adopting instead the Latin equivalent, Benedictus. Like every Jew, Spinoza had learned a handicraft, he was a grinder of lenses for optical instruments, and was thus enabled to earn an income sufficient for his modest wants. His skill, indeed, was such that lenses of his making were much sought after, and those found in his cabinet after his death fetched a high price. It was as an optician that he was first brought into connexion with Huygens and Leibnitz, and an optical *Treatise on the Rainbow*, written by him and long supposed to be lost, has been recently

discovered and reprinted by Dr Van Vloten. He was also fond of drawing as an amusement in his leisure hours, and Colerus had seen a sketch-book full of such drawings representing persons of Spinoza's acquaintance, one of them being a likeness of himself in the character of Masaniello.

The five years which followed the excommunication must have been devoted to concentrated thought and study. Before their conclusion Spinoza had parted company from Descartes, and the leading positions of his own system were already clearly determined in his mind. A number of the younger men in Amsterdam—many of them students of medicine or medical practitioners—had also come to regard him as their intellectual leader. A kind of philosophical club had been formed, including among its members Simon de Vries, John Bresser, Louis Meyer, and others who appear in Spinoza's correspondence. Originally meeting in all probability for more thoroughgoing study of the Cartesian philosophy, they looked naturally to Spinoza for guidance, and by-and-by we find him communicating systematic drafts of his own views to the little band of friends and students. The manuscript was read out and discussed at their meetings, and any points remaining obscure were referred to Spinoza for further explanation. An interesting specimen of such difficulties, propounded by Simon de Vries and resolved by Spinoza in accordance with his own principles, is preserved for us in Spinoza's correspondence. This Simon de Vries was a youth of generous impulses and of much promise. Being in good circumstances, he was anxious to show his gratitude to Spinoza by a gift of 2000 florins, which the philosopher half-jestingly excused himself from accepting. De Vries died young, and would fain have left his fortune to Spinoza, but the latter refused to stand in the way of his brother, the natural heir, to whom the property was accordingly left, with the condition that he should pay to Spinoza an annuity sufficient for his maintenance. The heir offered to fix the amount at 500 florins, but Spinoza accepted only 300, a sum which was regularly paid till his death. The written communications of his own doctrine referred to above belong to a period after Spinoza had removed from the neighbourhood of Amsterdam, but it has been conjectured that the *Short Treatise on God, on Man, and his Wellbeing*, which represents his thoughts in their earliest systematic form, was left by him as a parting legacy to this group of friends. It is at least certain, from a reference in Spinoza's first letter to Oldenburg, that such a systematic exposition was in existence before September 1661.¹ There are two dialogues somewhat loosely incorporated with the work which probably belong to a still earlier period. The short appendix, in which the attempt is made to present the chief points of the argument in geometrical form, is a forerunner of the *Ethics*, and was probably written somewhat later than the rest of the book. The term "Nature" is put more into the foreground in the *Treatise*, a point which might be urged as evidence of Bruno's influence,—the dialogues, moreover, being specially concerned to establish the unity, infinity, and self-containedness of Nature², but

¹ Various manuscript copies were apparently made of the treatise in question, but it was not printed, and dropped entirely out of knowledge till 1852, when Edward Bohmer of Halle lighted upon an abstract of it attached to a copy of Colerus's *Life*, and shortly afterwards upon a Dutch MS purporting to be a translation of the treatise from the Latin original. This was published in 1862 by Van Vloten with a re-translation into Latin. Since then a superior Dutch translation has been discovered, which has been edited by Professor Schaarschmidt and translated into German. Another German version with introduction and notes has been published by Sigwart based on a comparison of the two Dutch MSS.

² The fact that Spinoza nowhere mentions Bruno would not imply, according to the literary habits of those days, that he was not acquainted with his speculations and even indebted to them. There is no mention

the two opposed Cartesian attributes, thought and extension, and the absolutely infinite substance whose attributes they are—substance constituted by infinite attributes—appear here as in the *Ethics*. The latter notion—of substance—is said to correspond exactly to "the essence of the only glorious and blessed God." The earlier differs from the later exposition in allowing an objective causal relation between thought and extension, for which there is substituted in the *Ethics* the idea of a thoroughgoing parallelism.

Early in 1661 Spinoza's host removed to Rhynsburg near Leyden, the headquarters of the Collegiant brotherhood, and Spinoza removed with him. The house where they lived at Rhynsburg is still standing, and the road bears the name of Spinoza Lane. Very soon after his settlement in his new quarters he was sought out by Henry Oldenburg, the first secretary of the Royal Society. Oldenburg became Spinoza's most regular correspondent,—a third of the letters preserved to us are to or from him, and it appears from his first letter that their talk on this occasion was "on God, on infinite extension and thought, on the difference and the agreement of these attributes, on the nature of the union of the human soul with the body, as well as concerning the principles of the Cartesian and Baconian philosophies." Spinoza must therefore have unbosomed himself pretty freely to his visitor on the main points of his system. Oldenburg, however, was a man of no speculative capacity, and, to judge from his subsequent correspondence, must have quite failed to grasp the real import and scope of the thoughts communicated to him. From one of Oldenburg's early letters we learn that the treatise *De Intellectus Emendatione* was probably Spinoza's first occupation at Rhynsburg. The nature of the work also bears out the supposition that it was first undertaken. It is, in a manner, Spinoza's "organon,"—the doctrine of method which he would substitute for the corresponding doctrines of Bacon and Descartes, as alone consonant with the thoughts which were shaping themselves or had shaped themselves in his mind. It is a theory of philosophical truth and error, involving an account of the course of philosophical inquiry and of the supreme object of knowledge. It was apparently intended by the author as an analytical introduction to the constructive exposition of his system, which he presently essayed in the *Ethics*. But he must have found as he proceeded that the two treatises would cover to a large extent the same ground, the account of the true method merging almost inevitably in a state-

for example, of Hobbes throughout Spinoza's political writing, and only one casual reference to him in a letter, although the obligation of the Dutch to the English thinker lies on the surface. Accordingly full weight must be allowed to the internal evidence brought forward by Sigwart and others to prove Spinoza's acquaintance with Bruno's writings. But in regard to this question, and in regard to the elaborate researches directed to prove that the main determinations of Spinoza's thought are anticipated in the medieval philosophy of his own race, it must be said that these investigations are of comparatively little vital interest. Doubtless Spinoza's thought was coloured by his Hebrew origin and his Hebrew studies, from these sources, above all, he may have brought with him to the study of the dualistically expressed philosophy of Descartes the need, and the profound conviction, of unity. But the main strain of Spinoza's thought is sufficiently explained by reference to the Cartesian philosophy itself, the intellectual milieu of the time. Descartes's metaphysics can be shown to lead us to the very threshold of Spinoza's system, not only the general form, but the very terminology—substance, attributes, and modes—has waiting to be appropriated by an independent student.

³ Henry Oldenburg (c. 1626-1678) was a native of Bremen, but had settled in England in the time of the Commonwealth. Though hardly a scientific man himself, he had a genuine interest in science, and must have possessed social gifts. He was the friend of Boyle, and acquainted with most of the leaders of science in England as well as with many on the Continent. He delighted to keep himself in this way au courant with the latest developments, and lost no opportunity of establishing relations with men of scientific reputation. It was probably at the suggestion of Huygens that he bent his steps towards Spinoza's lodging.

ment of the truth reached by its means. The *Amendment of the Understanding* was therefore put aside unfinished, and was first published in the *Opera Posthuma*. Spinoza meanwhile concentrated his attention upon the *Ethics*, and we learn from the correspondence with his Amsterdam friends that a considerable part of book 1 had been communicated to the philosophical club there before February 1663. It formed his main occupation for two or three years after this date. Though thus giving his friends freely of his best, Spinoza did not cast his thoughts broadcast upon any soil. He had a pupil living with him at Rhynsburg whose character seemed to him lacking in solidity and discretion. This pupil (probably Albert Burgh, who afterwards joined the Church of Rome and penned a foolishly insolent epistle to his former teacher) was the occasion of Spinoza's first publication,—the only publication indeed to which his name was attached. Not deeming it prudent to initiate the young man into his own system, he took for a text-book the second and third parts of Descartes's *Principles*, which deal in the main with natural philosophy. As he proceeded he put Descartes's matter in his own language and cast the whole argument into a geometric form. At the request of his friends he devoted a fortnight to applying the same method to the first or metaphysical part of Descartes's philosophy, and the sketch was published in 1663, with an appendix entitled *Cogitata Metaphysica*, still written from a Cartesian standpoint (defending, for example, the freedom of the will), but containing hints of his own doctrine. The book was revised by Dr Meyer for publication and furnished by him, at Spinoza's request, with a preface, in which it is expressly stated that the author speaks throughout not in his own person but simply as the exponent of Descartes. A Dutch translation appeared in the following year.¹

In 1663 Spinoza removed from Rhynsburg to Voorburg, a suburban village about 2 miles from The Hague. His reputation had continued to spread. From Rhynsburg he had paid frequent visits to The Hague, and it was probably the desire to be within reach of some of the friends he had made in these visits—among others the De Witts—that prompted his change of residence. He had works in hand, moreover, which he wished in due time to publish, and in that connexion the friendly patronage of the De Witts might be of essential service to him. The first years at Voorburg continued to be occupied by the composition of the *Ethics*, which was probably finished, however, by the summer of 1665. A journey made to Amsterdam in that year is conjectured to have had reference to its publication. But, finding that it would be impossible to keep the authorship secret, owing to the numerous hands through which parts of the book had already passed, Spinoza determined to keep his manuscript in his desk for the present. In September 1665 we find Oldenburg twitting him with having turned from philosophy to theology and busying himself with angels, prophecy, and miracles. This is the first reference to the *Tractatus Theologico-Politicus*, which formed his chief occupation for the next four years. The aim of this treatise may be best understood from the full title with which it was furnished—*Tractatus Theologico-Politicus, continens dissertationes aliquot, quibus ostenditur libertatem philosophandi non tantum salva pietate et republice pace posse concedi sed eandem nisi cum pace republice ipsaque pietate tolli non posse*. It is, in fact, an eloquently reasoned defence of liberty of thought and speech in speculative matters. The external side of religion—its rites and observances—must of necessity be

subject to a certain control on the part of the state, whose business it is to see to the preservation of decency and order. But, with such obvious exceptions, Spinoza claims complete freedom of expression for thought and belief, and he claims it in the interests alike of true piety and of the state itself. The thesis is less interesting to a modern reader—because now generally acknowledged—than the argument by which it is supported. Spinoza's position is based upon the thoroughgoing distinction drawn in the book between philosophy, which has to do with knowledge and opinion, and theology, or, as we should now say, religion, which has to do exclusively with obedience and conduct. The aegis of religion, therefore, cannot be employed to cover with its authority any speculative doctrine, nor, on the other hand, can any speculative or scientific investigation be regarded as putting religion in jeopardy. Spinoza undertakes to prove his case by the instance of the Hebrew Scriptures. Scripture deals, he maintains, in none but the simplest precepts, nor does it aim at anything beyond the obedient mind; it tells us nought of the divine nature, but what men may profitably apply to their lives. The greater part of the treatise is devoted to working out this line of thought, and in so doing Spinoza consistently applies to the interpretation of the Old Testament those canons of historical exegesis which are often regarded as of comparatively recent growth. The treatise thus constitutes the first document in the modern science of Biblical criticism. It was published in 1670, anonymously, printer and place of publication being likewise disguised (*Habitu græci apud Henricum Kunraht*). The storm of opposition which it encountered showed that these precautions were not out of place. It was synodically condemned along with Hobbes's *Leviathan* and other books as early as April 1671, and was consequently interdicted by the states-general of Holland in 1674, before long it was also placed on the Index by the Catholic authorities. But that it was widely read appears from its frequent re-issue with false title-pages, representing it now as an historical work and again as a medical treatise. Controversialists also crowded into the lists against it. A translation into Dutch appears to have been proposed, but Spinoza, who foresaw that such a step would only increase the commotion which was so distasteful to him, steadily set his face against it. No Dutch translation appeared till 1693.

The same year in which the *Treatise* was published Spinoza removed from his suburban lodging at Voorburg into The Hague itself. He took rooms first on the Veerkay with the widow Van de Velde, who in her youth had assisted Grotius to escape from his captivity at Loewenstein. This was the house afterwards occupied by Colerus, the worthy Lutheran minister who became Spinoza's biographer. But the widow insisted on boarding her lodger, and Spinoza presently found the expense too great for his slender purse. He accordingly removed to a house on the Pavloen Gracht near at hand, occupied by a painter called Van der Spijck. Here he spent the remaining years of his life in the frugal independence which he prized. Colerus gives particulars which enable us to realize the almost incredible simplicity and economy of his mode of life. He would say sometimes to the people of the house that he was like the serpent who forms a circle with his tail in his mouth, meaning thereby that he had nothing left at the year's end. His friends came to visit him in his lodgings, as well as others attracted by his reputation—Leibnitz among the rest—and were courteously entertained, but Spinoza preferred not to accept their offers of hospitality. He spent the greater part of his time quietly in his own chamber, often having his meals brought there and sometimes not leaving it for two or three days together when absorbed in his studies. On one occasion he did not leave the house for three

¹ The title of the Latin original ran—*Renati des Cartes Principiorum Philosophiæ pars I et II, more geometrico demonstratæ per Benedictum de Spinoza Amstelodamensem. Accesserunt ejusdem Cogitata Metaphysica*.

months "When he happened to be tired by having applied himself too much to his philosophical meditations, he would go downstairs to refresh himself, and discoursed with the Van der Spieks about anything that might afford matter for an ordinary conversation, and even about trifles. He also took pleasure in smoking a pipe of tobacco, or, when he had a mind to divert himself somewhat longer, he looked for some spiders and made them fight together, or he threw some flies into the cobweb, and was so well pleased with the result of that battle that he would sometimes break into laughter" (Colerus). He also conversed at times on more serious topics with the simple people with whom he lodged, often, for example, talking over the sermon with them when they came from church. He occasionally went himself to hear the Lutheran pastor preach—the predecessor of Colerus—and would advise the Van der Spieks not to miss any sermon of so excellent a preacher. The children, too, he put in mind of going often to church, and taught them to be obedient and dutiful to their parents. One day his landlady, who may have heard strange stories of her solitary lodger, came to him in some trouble to ask him whether he believed she could be saved in the religion she professed. "Your religion is a good one," said Spinoza, "you need not look for another, nor doubt that you will be saved in it, provided that, while you apply yourself to piety, you live at the same time a peaceable and quiet life." Only once, it is recorded, did Spinoza's admirable self-control give way, and that was when he received the news of the murder of the De Witts by a frantic mob in the streets of The Hague. It was in the year 1672, when the sudden invasion of the Low Countries by Louis XIV raised an irresistible clamour for a military leader and overthrow the republican constitution for which the De Witts had struggled. John De Witt had been Spinoza's friend, and had bestowed a small pension upon him, he had Spinoza's full sympathy in his political aims. On receiving the news of the brutal murder of the two brothers, Spinoza burst into tears, and his indignation was so roused that he was bent upon publicly denouncing the crime upon the spot where it had been committed. But the timely caution of his host prevented his issuing forth to almost certain death. Not long after Spinoza was himself in danger from the mob, in consequence of a visit which he paid to the French camp. He had been in correspondence with one Colonel Stoupe, a Swiss theologian and soldier, then serving with the prince of Condé, the commander of the French army at Utrecht. From him Spinoza received a communication enclosing a passport from the French commander, who wished to make his acquaintance and promised him a pension from the French king at the easy price of a dedication to his majesty. Spinoza went to Utrecht, but returned without seeing Condé, who had in the meantime been called elsewhere, the pension he civilly declined. There may have been nothing more in the visit than is contained in this narrative, but on his return Spinoza found that the populace of The Hague regarded him as no better than a spy. The town was full of angry murmurs, and the landlord feared that the mob would storm his house and drag Spinoza out. Spinoza quieted his fears as well as he could, assuring him that as soon as the crowd made any threatening movement he would go out to meet them, "though they should save me as they did the poor De Witts. I am a good republican and have never had any aim but the honour and welfare of the state." Happily the danger passed off without calling for such an ordeal.

In 1673 Spinoza received an invitation from the elector palatine to quit his retirement and become professor of philosophy in the university of Heidelberg. The offer was couched in flattering terms, and conveyed an express

assurance of "the largest freedom of speech in philosophy, which the prince is confident that you will not misuse to disturb the established religion." But Spinoza's experience of theological sensitiveness led him to doubt the possibility of keeping on friendly terms with the established religion, if he were placed in a public capacity. Moreover, he was not strong, he had had no experience of public teaching, and he foresaw that the duties of a chair would put an end to private research. For all these reasons he courteously declined the offer made to him. There is little more to tell of his life of solitary meditation. In 1675 we learn from his correspondence that he entertained the idea of publishing the *Ethics*, and made a journey to Amsterdam to arrange matters with the printer. "But, whilst I was busy with this," he writes, "the report was spread everywhere that a certain book of mine was in the press, wherein I endeavoured to show that there was no God, and this report found credence with many. Whereupon certain theologians (themselves perhaps the authors of it) took occasion to complain of me to the prince and the magistrates, moreover, the stupid Cartesians, because they are commonly supposed to side with me, desiring to free themselves from that suspicion, were diligent without ceasing in their execrations of my doctrines and writings, and are as diligent still." As the commotion seemed to grow worse instead of subsiding, Spinoza consigned the manuscript once more to his desk, from which it was not to issue till after his death. His last literary work was the unfinished *Tractatus Politicus* and the preparation of notes for a new edition of the *Tractatus Theologico-Politicus*, in which he hoped to remove some of the misunderstandings which the book had met with. The *Tractatus Politicus* develops his philosophy of law and government on the lines indicated in his other works, and connects itself closely with the theory enunciated by Hobbes a generation before. Consumption had been making its insidious inroads upon Spinoza for many years, and early in 1677 he must have been conscious that he was seriously ill. On Saturday the 20th of February he sent to Amsterdam for his friend Dr Meyer. On the following day the Van der Spieks, having no thought of immediate danger, went to the afternoon service. When they came back Spinoza was no more, he had died about three in the afternoon with Meyer for the only witness of his last moments. Spinoza was buried on the 25th of February "in the new church upon the Spuy, being attended," Colerus tells us, "by many illustrious persons and followed by six coaches." He was little more than forty-four years of age.

Spinoza's effects were few and realized little more than was required for the payment of charges and outstanding debts. "One need only cast one's eyes upon the account," says his biographer, "to perceive that it was the inventory of a true philosopher. It contains only some small books, some engravings, a few lenses, and the instruments to polish them." His desk, containing his letters and his unpublished works, Spinoza had previously charged his landlord to convey to Jan Rieuwertz, a publisher in Amsterdam. This was done, and the *Opera Posthuma* appeared in the same year, without the author's name, but with his initials upon the title page. They were furnished with a preface written in Dutch by Jarig Tolks, a Mennonite friend of Spinoza's, and translated into Latin by Dr Meyer. Next year the book was proscribed in a violently worded edict by the states of Holland and West Friesland. The obloquy which thus gathered round Spinoza in the later years of his life remained settled upon his memory for a full hundred years after his death. Hume's casual allusion to "this famous atheist" and his "hideous hypothesis" is a fair specimen of the tone in which he is usually referred to, people talked about Spinoza, Lessing said, "as if he were a dead dog." The change of opinion in this respect may be dated from Lessing's famous conversation with Jacobi in 1780. Lessing, Coethe, Herder, Novalis, and Schleiermacher, not to mention philosophers like Schelling and Hegel, muted in recognizing the unique strength and sincerity of Spinoza's thought, and in setting him in his rightful place among the speculative leaders of mankind. Transfused into their writings, his spirit has had a large share in moulding the philosophic thought

of the 19th century, and it has also been widely influential beyond the schools. Instead of his atheism Hegel speaks of his acosmism, and Novalis dubs him a God intoxicated man. Schleiermacher's fine apostrophe is well known, in which he calls upon us to "offer a lock of hair to the manes of the holy and excommunicated Spinoza."

Spinoza's personal appearance is described by Colerus from the accounts given him by many people at The Hague who knew him familiarly. "He was of a middle size, and had good features in his face, the skin somewhat dark, black curled hair, and the long eyebrows of the same colour, so that one might easily know from his looks that he was descended from the Portuguese Jews." Leibnitz also gives a similar description. "The celebrated Jew Spinoza had an olive complexion and something Spanish in his face. These characteristics are preserved in a portrait in oil in the Wollenbuttel library, which was probably the original of the (in that case unsuccessfully rendered) engraving prefixed to the *Opera Posthuma* of 1677. This portrait has recently been photographed for Dr Martineau's *Study of Spinoza*. In 1860 a statue was erected to Spinoza at The Hague by international subscription among his admirers.

Spinoza's philosophy is a thoroughgoing pantheism, which has both a naturalistic and a mystical side. The foundation of the system is the doctrine of one infinite substance, of which all finite existences are modes or limitations (modes of thought or modes of extension). God is thus the immanent cause of the universe, but of creation or will there can be no question in Spinoza's system. God is used throughout as equivalent to nature (*Deus sive natura*). The philosophical standpoint comprehends the necessity of all that is—a necessity that is none other than the necessity of the divine nature itself. To view things thus is to view them, according to Spinoza's favourite phrase, *sub specie eternitatis*. Spinoza's philosophy is fully considered in the article *CARTESIANISM* (see vol. v p. 152 sq.).

Literature.—The contents of the *Opera Posthuma* included the *Ethics*, the *Tractatus Politicus*, and the *De Intellectus Emendatione* (the last two unfinished), a selection from Spinoza's correspondence, and a *Compendium of Hebrew Grammar*. The *Treatise on the Rainbow*, supposed to be lost, was published anonymously in Dutch in 1687. The first collected edition of Spinoza's works was made by Paulus in 1802, there is another by Gfrörer (1830), and a third by Bruder (1843-46) in three volumes. Van Vloten's volume, published in 1862, *Ad Benedicti de Spinoza opera quæ supersunt omnia supplementum*, is uniform with Bruder's edition so as to complete it by a supplementary volume. It contained the early treatise *De Deo et homine*, the *Treatise on the Rainbow*, and several fresh letters. A complete and authoritative edition has only recently been achieved by Dr Van Vloten and Professor J P N Land. The work was undertaken by them for the Spinoza Memorial Committee formed in Holland to celebrate the bicentenary of the philosopher's death, the funds remaining after the erection of the statue mentioned above were devoted to the publication of this handsome edition (2 vols., 1882-83). An English translation of *The Chief Works of Spinoza*, by R. H. M. Elwes, appeared in 1883, and a separate translation of the *Ethics* by W. H. White was published in the same year, previous translations were unscholarly in execution. The main authority for Spinoza's life is the sketch published in 1705, in Dutch, with a controversial sermon against Spinozism, by Johannes Colerus. The French version of this *Life* (1706) has been several times reprinted as well as translated into English and German. The English version, also dating from 1706, has been reprinted by Mr Frederick Pollock at the end of his work, *Spinoza, his Life and Philosophy* (1880). Mr Pollock's book and Dr Martineau's *Study of Spinoza* (1882), both admirable pieces of work, are in a manner complementary, and may with advantage be studied together. In his introduction Mr Pollock gives a list of the biographical sources, and also some account of the early literature relating to Spinoza. The Spinoza literature in more recent times has become so extensive as to forbid quotation. A. van der Lande's *Benedictus Spinoza Bibliografie* (The Hague, 1871) is a classified catalogue as nearly as possible complete down to that date. (A. SE.)

SPIRES (Germ *Speyer* or *Speier*), the chief town of the Rhenish palatinate, Bavaria, and formerly a free imperial city, is situated on the left bank of the Rhine, at the mouth of the Speyerbach, 21 miles to the south of Worms. The principal streets are broad but irregular, and the general appearance of the town little corresponds to its high antiquity, owing to the fact that it was burned by the French in 1689. The only important ancient building that has survived the flames is the cathedral, a very large and imposing basilica of red sandstone, and one of the noblest examples of Romanesque architecture now extant. Beyond the general interest attaching to it as one of the old

Romanesque churches of the Rhineland, Spires cathedral has a peculiar importance in the history of architecture as probably the earliest Romanesque basilica in which the nave as well as the side arcades was vaulted from the first. Built in 1030-61 by Conrad II. and his successor, this church has had a chequered history, its disasters culminating in 1689, when the soldiers of Louis XIV. burned it to the bare walls and scattered the ashes of the eight German emperors who had been interred in the kings' choir. Restored in 1772-84 and provided with a vestibule and façade, it was again desecrated by the French in 1794, but in 1846-53 it was once more thoroughly restored and adorned in the interior with gorgeous frescos at the expense of the king of Bavaria. The large cathedral bowl (Domnappf) in front of the west façade formerly marked the boundary between the episcopal and municipal territories. Each new bishop on his election had to fill the bowl with wine, while the burghers emptied it to his health. The heathen tower to the east of the church, on foundations supposed to be Roman, was probably part of the town wall built in 1080 by Bishop Rüdger. Of the Retscher, or imperial palace, so called because built after the model of the Hradschin at Prague, only a mouldering fragment of wall remains. It was in this palace that the famous diet of Spires met in 1529, at which the Reformers first received the name of Protestants. The Altportal (alta porta), a fine old gateway of 1246, is a relic of the free imperial city. Among the modern buildings are several churches and schools, a museum and picture gallery, &c. Spires, although rebuilt in 1697, has never recovered from the cruel injuries inflicted by the French in 1689. Its trade is insignificant, although it still has a free harbour on the Rhine. Its manufactures include paper, tobacco and cigars, sugar, sugar of lead, vinegar, beer, and leather. Vines and tobacco are grown in the neighbourhood. The population in 1880 was 15,589 and in 1885 16,228.

Spres, known to the Romans as *Augusta Nemetae* or *Nemetæ*, and to the Gauls as *Aviomagus*, is one of the oldest towns on the Rhine. The modern name appears first, under the form *Spira*, about the 7th century. Captured by Julius Caesar in 47 B.C., it was repeatedly destroyed by the barbarian hordes in the first few centuries of the Christian era. The town had become an episcopal seat in the 4th century, but heathenism supervened, and the present bishopric dates from 610. In 830 Spira became part of the Frankish empire, the emperors having a "palatium" here, and it was especially favoured by the Salic imperial house. The contentions between the bishops and the citizens were as obstinate and severe as in any other city of Germany. The situation of the town opposite the mouths of several roads through the Rhine valley early fostered its trade, in 1294 it rose to be a free imperial city, although it owned no territory beyond its walls and had a population of less than 30,000. It enjoyed great renown as the seat of the imperial supreme court from 1527 till 1689, it was fifth among the free cities of the Rhine, and had a vote in the Upper Rhenish diet. Numerous imperial diets assembled here. From 1801 till 1814 it was the capital of a department of France, but it was restored to Bavaria in the latter year. By the peace of Spres in 1544 the Hapsburgs renounced their claims to the crown of Sardina.

SPIRITUALISM. The term "spiritualism" is used by philosophical writers to denote the opposite of materialism. It is also used in a narrower sense to describe the belief that the spiritual world manifests itself by producing in the physical world effects inexplicable by the known laws of nature. The belief in such occasional manifestations has probably existed as long as the belief in the existence of spirits apart from human bodies, and a complete examination into it would involve a discussion of the religions of all ages and nations. In 1848, however, a peculiar form of it, believed to be based on abundant experimental evidence, arose in America and spread there with great rapidity and thence over the civilized world. To this movement, which has been called "modern spiritualism," the discussion in the present article is confined. The movement began in a single family. In 1848 a Mr and

Mrs Fox and their two daughters, living at Hydeville (Wayne), New York, were much disturbed by unexplained knockings. At length Kate Fox discovered that the cause of the sounds was intelligent and would make raps as requested, and, communication being established, the rapper professed to be the spirit of a murdered pedlar. An investigation into the matter seemed to show that none of the Fox family were concerned in producing the rappings, but the evidence that they were not concerned is insufficient, although similar noises had been noticed occasionally in the house before they lived there. It was, however, at Rochester, where the two Fox girls soon afterwards went to live with a married sister (Mrs Fish) that modern spiritualism assumed its present form, and that communication was, as it was believed, established with lost relatives and deceased eminent men. The presence of certain "mediums" was required to form the link between the worlds of the living and of the dead, and Kate Fox and her sister were the first mediums. Spiritualists do not as yet claim to know what special qualities in mediums enable spirits thus to make use of them. The earliest communications were carried on by means of "raps," or, as Mr Crookes calls them, "percussive sounds." It was agreed that one rap should mean "no" and three "yes," while more complicated messages were—and are—obtained in other ways, such as calling over or pointing to letters of the alphabet, when raps occur at the required letters.

The idea of communicating with the departed was naturally attractive even to the merely curious, still more to those who were mourning for lost friends, and most of all to those who believed that this was the commencement of a new revelation. The first two causes have attracted many inquirers, but it is the last that chiefly gives to modern spiritualism its religious aspect. Many came to witness the new wonder, and the excitement and interest spread rapidly. "Spirit-circles" were formed in several families, and other mediums discovered, exhibiting phenomena of various kinds (see below). The interest in mesmerism and the phenomena of hypnotic trance, which was widely diffused at this time both in America and Europe (see MAGNETISM, ANIMAL, vol. xv p. 277 sq.), was favourable to the new idea. Information about other worlds and from higher intelligences was thought to be obtained from persons who could be put into the sleep-waking state, of whom Andrew Jackson Davis was in America the most prominent example. His work, *Nature's Divine Revelations* (New York, 1847), was alleged to have been dictated in "clairvoyant" trance. Many reputed "clairvoyants" developed into mediums. The movement spread like an epidemic. There is very little evidence to show that it arose anywhere spontaneously¹, but those who sat with the Foxes were often found to become mediums themselves and then in their turn developed mediumship in others. The mere reading of accounts of seances seemed to develop the peculiar susceptibility in some persons, while others, who became mediums ultimately, did so only after prolonged and patient waiting.

There seems to have been little practical interest in spiritualism in Europe till Mrs Haydon, a professional medium from Boston, came over in 1852. It spread like wildfire within a few months of her arrival,—its first development being in the form of a mania for table-turning, which seems to have prevailed all over Europe in 1853.

¹ It is possible that the family of Dr Phelps were unaware of the "Rochester knockings" when the disturbances began in his house at Stratford, Connecticut, in 1850 (see Capron's *Modern Spiritualism, its Facts, &c.*), but these disturbances, as recorded, have a closer resemblance to the ordinary occurrences at a spiritualistic seance than those which took place at Tedworth in 1661 (see Glamvill's *Sadducius'us Triumphatus*) and at Slawensik in 1806 (see Kerner's *Scherin von Prorost*), and others too numerous to mention.

Daniel Dunglas Home, the next medium of importance who appeared in London, came over from America in 1855. But it was at Keighley in Yorkshire that spiritualism as a religious movement first made any mark in England, and it was there that the first English spiritualistic periodical, the *Yorkshire Spiritual Telegraph*, was started in 1855. The extent to which the movement has spread and the present number of spiritualists are very difficult to estimate. Vague calculations have from time to time been attempted. In 1867 one spiritualist estimated the number in America at 11,000,000 or two fifths of the population, and another has held 3,000,000 to be an extreme estimate (see *Spiritual Magazine* for 1867). The periodicals devoted to spiritualism may perhaps be taken to indicate the present state of the movement. There are in England two weekly newspapers, *Light* and *The Medium and Daybreak*, one of these has advertisements of Sunday meetings in sixty different towns and in eighty different rooms. The spiritualistic journals outside Great Britain number about 100, though probably only about a quarter of these are of any importance. Of these 30 are in English (26 published in America and 4 in the Australian colonies), 15 to 20 in French, and 6 in German. But nearly 40 are published in Spanish in Spain and South America. Private circles which meet regularly are believed to be numerous in England, and there are numerous public and semi public trance-speaking and clairvoyant mediums, especially among the miners in the north.

In the present article it is impossible to give an exhaustive catalogue of the phenomena and modes of communication of modern spiritualism. Many have not now appeared for the first time in history, though it is difficult to suppose any historical connexion between the new developments and the old. Perhaps the most striking parallelism is that between the proceedings at modern seances and those connected with the later Greek oracles.² The greater part of the phenomena may be divided into two classes. To the first and earliest developed class belong what may be called the physical phenomena of spiritualism,—those, namely, which, if correctly observed and due neither to conscious or unconscious trickery nor to hallucination on the part of the observers, exhibit a force hitherto unknown to science, acting in the physical world otherwise than through the brain or muscles of the medium. The earliest of these phenomena were the raps already spoken of and other sounds occurring without apparent physical cause, and the similarly mysterious movements of furniture and other objects; and these were shortly followed by the ringing of bells and playing of musical instruments. Later followed the appearance of lights, quasi-human voices, musical sounds, produced, it is supposed, without instruments, the "materialization" or presence in material form of what seem to be human hands and faces, and ultimately of complete figures, alleged to be not those of any person present, and sometimes claimed by witnesses as deceased relatives, "psychography," or "direct writing and drawing," asserted to be done without human intervention, "spirit-photography," or photographing of human and other forms invisible to all but specially endowed seers, unfastening of cords and bonds, elongation of the medium's body, handling of red-hot coals, and the apparent passage of solids through solids without disintegration. The phenomena observed at Tedworth belong to this class. Somewhat similar was the Cock Lane ghost in 1762.³ A practice of causing heavily loaded tables to rise by "magic" seems to have existed among the German Jews in the 17th century.⁴ Kerner records movements

of objects in connexion with Madame Hauffe in 1825-28,¹ and such movements also occurred in presence of the so-called electric girl in 1846.² The second class of phenomena, which we may call the automatic, consists in table-tilting and turning with contact, writing, drawing, &c., through the medium's hand, convulsive movements and involuntary dancing, entrancement, trance speaking, and personation by the medium of deceased persons, attributed to temporary "possession", seeing spirits and visions and hearing phantom voices. This class bears affinity to some of the phenomena of hypnotism and of certain nervous complaints, to certain epidemics of the Middle Ages,³ and to phenomena that have occurred at some religious revivals. According to quotations given by Chevreul,⁴ the divining-rod was used at the end of the 17th century for obtaining answers to questions, as table-tilting now is. In a third class must be placed the cure of disease by healing mediums. This cannot well be treated apart from mesmeric healing and "faith cures" and "mind cures," and belongs to medical psychology.

The class of automatic phenomena are much the commonest. The investigations of Carpenter on unconscious cerebration and of Faraday on unconscious muscular action⁵ have shown that it is not necessary to look outside the medium's own brain and organism for the explanation of such things as automatic writing and table turning. It is about the matter communicated by these means that the controversy now turns. Spiritualists maintain that true information is thus given, provably unknown to the medium or other persons present, or at least expressed in a way obviously beyond their powers to originate. Another view, which is now gaining ground, is that the information in some exceptional cases does not come from the mind of the medium, but is due to the influence wrought on his mind by that of other persons, and more than this is not proved.⁶

At no period of the spiritualistic movement has the class of physical phenomena been accepted altogether without criticism. Most spiritualists know that much fraud in connexion with them has been discovered—frequently by spiritualists themselves—and that the conditions favourable to obtaining them are often such as favour fraud. It is with a full knowledge of these difficulties in the way of investigation that they maintain that unmistakably genuine phenomena are of constant occurrence. Many volumes containing accounts of such phenomena have been printed, and appeal is often made to the mass of evidence so accumulated. "No physical science can array a tithe of the mass of evidence by which psychism" (*i.e.*, what is usually called spiritualism) "is supported," says Sergeant Cox.⁷ But the majority of these accounts have scarcely any scientific value. Spiritualists have, as a rule, sought to convince not by testimony but by ocular demonstration. Yet, if there is not a mass of scientific evidence, there are a number of witnesses—among them distinguished men of science and others of undoubted intelligence—who have convinced themselves by observation of the genuineness of the phenomena,—a fact of undeniable importance, even without careful records, when the witnesses are otherwise known to be competent and trustworthy observers. Mr Maskelyne has affirmed⁸ that he has witnessed table-turning where he was satisfied that there was neither trickery nor unconscious muscular action. Moreover, if

the phenomena are not genuine, we have to assume a large amount of apparently aimless fraud.

Amongst the proposed explanations of these phenomena that of hallucination need not detain us long. Sensory hallucination of several persons together who are not in a hypnotic state is a rare phenomenon, and therefore not a probable explanation. Moreover, it cannot be regarded as being generally applicable, partly because material traces of what occurs often remain, and partly because of the general agreement not only of all the witnesses but of all the senses as to what is perceived, as distinguished from what is inferred. Nevertheless something of the kind may occasionally have happened, especially at some of the seances of Home.⁹ If collective hallucination really occurs at seances, it is a very interesting fact, and deserves to be carefully studied.

What may broadly be called conjuring is, however, a much more probable explanation of most of the recorded phenomena, and in the vast majority of cases the witnesses do not seem to have duly appreciated the possibilities of conjuring, nor to have taken sufficient precautions to exclude it. Besides, not even a conjuror knows all the possibilities of his art and can describe in detail all the accidental circumstances which may on any particular occasion favour deception, and perhaps never exactly recur. We require, therefore, to know not only that the witness is careful and accurate but that he has allowed a sufficiently wide margin for the possibilities of conjuring, and some leading spiritualists do not allow this. It is often urged that mediums are not conjurors because they frequently fail, whereas "imposture can be reproduced at will," and because they can produce the phenomena in private rooms, and under conditions which exclude the possibility of conjuring. But the phenomena produced by mediums in private rooms would generally be uninteresting and unsuited to public performance, so that it would not pay a professional conjuror to practise them. Amateur conjurors might do something in this way, and the present writer has seen one imitate successfully some of the phenomena of professional mediums for "direct writing", but to compete with mediums on really equal terms the conjuror must have the same conditions throughout, and this is difficult to arrange, since it involves securing witnesses who are doubtful as to whether what they see is conjuring or not. Still more important to the conjuror is that very privilege of failing whenever he pleases, so largely used by mediums, that he may avail himself of accidental opportunities for trickery, which would be interfered with by a settled programme. The extent to which the absence of programme obtains at seances appears from the following statement by a leading spiritualist who writes under the *nom de plume* of "M. A. (Oxon)": "In 99 out of every 100 cases people do not get what they want or expect. Test after test, cunningly devised, on which the investigator has set his mind, is put aside, and another substituted."¹⁰ In other words, the evidence is rarely strictly experimental, and thus not only gives facilities for fraud but makes it necessary to allow a much larger margin for accidents, mistakes, and mal observation. It must be borne in mind that the most excellent moral character in the medium is no guarantee against trickery, unless it can be proved that he was in no abnormal mental condition when the phenomena occurred, for extraordinary deceptions have been carried on by hysterical patients and others with no apparent motive but a desire to secure attention.

One of the possibilities to be allowed for is that of un-

usual unseular endowment in the medium. For instance, in 1851, the remarkable loud double raps occurring in the presence of the Fox girls, which in 1849 had puzzled several investigating committees at Rochester, were explained by Professors Flint, Lee, and Coventry of Buffalo as produced by rapidly partially dislocating and restoring the knee and other joints. They stated that they had experimented with another lady who could do the same, and, challenged by Mrs. Fish, they tried some experiments with her and Marguerita Fox which strongly supported their view.

Besides the general arguments for supposing that the physical phenomena of spiritualism may be due to conjuring there are two special reasons which gain in force as time goes on. (1) Almost every medium who has been prominently before the public has at some time or other been detected in fraud, or what cannot be distinguished from fraud except on some violently improbable hypothesis, and (2), although it is easy to devise experiments of various kinds which would place certain phenomena above the suspicion of conjuring, by eliminating the necessity for continuous observation on the part of the investigators, there is no good evidence that such experiments have ever succeeded. Nevertheless there does exist evidence for the genuineness of the physical phenomena which deserves consideration. Count Agénor de Gasparin, in his *Tables Tournantes* (Paris, 1854), gives an account of what seem to have been careful experiments with his own family and friends, which convinced him that by some unknown force tables could be got to move without contact. He did not believe that spirits had anything to do with it. His experiments were conducted in broad daylight and with sceptical witnesses (whose testimony, however, he does not give) looking on outside the circle. The minutes of the sub-committee No. 1 of the committee of the Dialectical Society (*op cit*, pp. 373-391) report that tables moved without contact, whilst all the persons present knelt on chairs (the backs of which were turned to the table), with their hands on the backs. The report, however, would be of greater value if the names of the medium and of the working members of the committee were given—we only know that of Sergeant Cox—and if they had written independent accounts of what they witnessed. The conditions of some of Mr. Crookes's experiments with D. D. Home on alterations in the weight of a partially suspended board¹ appear to have been so simple that it is difficult to imagine how the witnesses can have been deceived. Some very remarkable evidence is contained in "Researches in Spiritualism during the Year 1872-3," by "M. A. (Oxon)," published in a spiritualistic periodical called *Human Nature*, March and August 1874. The papers give accounts of phenomena obtained through the writer's own mediumship, generally in the presence of one or two friends, and extending over almost the whole range of spiritualistic manifestations.

But what chiefly interests spiritualists is the assurance of life and progress after death, and the moral and religious teaching, which they obtain through automatic writing and trance speaking. It was discovered very early in the movement that the accuracy of these communications could not always be relied on, but it is maintained by spiritualists that by the exercise of the reason and judgment, by prolonged acquaintance with particular communicating intelligences, and by proofs of identity with persons known to have been trustworthy on earth, it is possible to obtain valuable information from beings not infallible, but with the knowledge of spirit life superadded to their earthly experience. Still the agreement between

communications so received has not been sufficiently great for anything like a universal spiritualistic creed to have been arrived at. In France the doctrine of successive reincarnations with intervals of spirit life promulgated by Allan Kardec (Léon Hippolyte Denisart Rivail) forms a prominent element of spiritualistic belief. This view has, however, made but little way in England and America, where the opinions of the great majority of spiritualists vary from orthodox Christianity to Unitarianism of an extreme kind. Probably it would be impossible to unite spiritualists in any creed, which, besides the generally accepted belief in God and immortality, should postulate more than the progress of the spirit after death, and the power of some of the dead to communicate with the living by means of mediums.

Spiritualism has been accused of a strong tendency to produce insanity, the charge, however, seems to be in the main a mistaken inference from the fact that the delusions of the insane not unfrequently take the form of supposed converse with invisible beings. It is, however, probable that the spiritualistic theories of possession and obsession sometimes injure persons with incipient insane impulses, by weakening their sense of responsibility for these and their efforts to control them. Spiritualism has also been accused of fostering free love and other doctrines subversive of society. But this charge too has been made without adequate grounds, for, though certain spiritualistic bodies have at times taught such doctrines, they have always been repudiated by the mass of spiritualists. The great scandal of spiritualism is undoubtedly the encouragement it gives to the immoral trade of fraudulent mediumship.

In addition to the works already mentioned, the student, for a general idea of the whole subject, should consult the following—E. W. Capron, *Modern Spiritualism, its Facts, &c.*, Boston, 1855, for the early history of the movement in America; Edmunds and Dexter, *Spiritualism*, New York, 1854-55; R. Hare, *Experimental Investigations of the Spirit Manifestations*, New York, 1856; Allan Kardec, *Le Livre des Esprits*, 1st ed. 1853, Mrs. De Morgan, *From Matter to Spirit*, London, 1863, with preface by Professor De Morgan; Alfred Russel Wallace, *Miracles and Modern Spiritualism*, 1876; M. A. (Oxon), *Spirit Identity and Spirit Teaching*, Zollnor, *Wissenschaftliche Abhandlungen* (the part relating to spiritualism has been translated into English under the title *Transcendental Physics* by C. C. Massey). A succinct account of typical frauds of spiritualism is contained in D. D. Home's *Lights and Shadows of Spiritualism*, 2d ed., 1877-78. (E. M. S.)

SPITZBERGEN This group of rocky, barren, and Situated. snow-clad islands, lost in the solitudes of the Arctic Ocean, 400 miles north-north-west of the North Cape of Norway (see vol. xix. pl. II), but nevertheless well known for at least four centuries to European whalers and seal-hunters, has of late acquired new interest from the scientific expeditions by which it has been selected either as a base for attempts to reach the north pole or as a field in which to inaugurate a new era of scientific exploration in the arctic regions. From Spitzbergen Parry started in 1827 on the sledge journey which brought him within 480 miles of the pole; it was the starting-point of the investigations which led Charles Martins to his brilliant generalizations of the flora, present and past, of the earth, and numerous Swedish expeditions from 1858 onwards have accumulated an amount of knowledge, so vast and so important, as to be comparable only with the results of the great equatorial and arctic journeys of the first years of the 19th century.

The Spitzbergen archipelago, lying between 76° 30' and Islands. 80° 30' N. lat. and 10° and 30° E. long.—half way between Greenland and Nova Zembla—consists of six large and a great number of smaller islands. The chief, that of West Spitzbergen, shaped like a wedge pointed towards the south, and deeply indented on the west and north by long branching fjords, has an area of nearly 15,200 square miles. High mountains, reaching 4560 feet in the Horn Sound Tind, cover its southern parts, while a wide plateau,

¹ *Quart. Journ. of Science*, July and October 1871, republished, with other papers by Mr. Crookes, under the title of *Researches on the Phenomena of Spiritualism*, 1874-76.

with an altitude of from 1500 to 2000 feet and covered by a thick ice-sheet, occupies the north. Several fjords—Horn Sound, Bel Sound, Ice Fjord (15 miles wide and 80 long), and the double fjord of King's Bay and Cross Bay on the west, and Læfde, Wiide, and Lomme Bays on the north—deeply penetrate the island. One of the ramifications (Dickson Bay) of the beautiful Ice Fjord, 150 fathoms deep, nearly reaches the head of Wiide Bay, so as almost to divide the island. A long narrow island, Prince Charles's

Map of Spitzbergen.

Foreland, with peaks of nearly 5000 feet high, runs parallel to part of the west coast of West Spitzbergen, from which it is separated by a narrow strait. The broad Stor (Great) Fjord, or Wiide Jans Water, separates the main island from two others to the east,—Stans Foreland (2500 square miles) and Barents Land (580 square miles). Formerly these were considered as one, and named Edge Island, until the narrow Walter Thymen Strait which parts them was discovered. A few peaks, estimated at from 1600 to 2000 feet high, protrude above the snow and ice by which these two imperfectly explored islands are covered. To the north-east of West Spitzbergen, separated from it by Hinlopen Strait (7 to 60 miles in breadth) lies North-East Land, with an area of about 6200 square miles. Its western and northern coasts are indented by several bays and fjords, the southern and eastern shores, on account of the masses of ice by which they are constantly girt, remain unexplored. This island appears like a broad plateau covered by an ice-sheet 2000 to 3000 feet in thickness, from which a few peaks protrude. Slowly moving towards the east, this immense sheet of ice discharges into the sea by a huge ice-wall, unbroken by promontories for 150 miles, thus forming the broadest glacier known,—Dickson's glacier. Eastwards from this group of islands, 100 miles to the north east of Stans Foreland, rises another island, measuring 90 miles from west to east. Marked either Gillis's Land or Wiche's Land in earlier maps, it was seen from Spitzbergen as a snow-clad mass mingling with the fogs of the sea by a Swedish expedition, and later on by Heuglin and Zeil, but it was not until 1872 that the Norwegian whalers Altman, Johnsen, and Nilsen reached it from the east and nearly circumnavigated it. After some discussion about its name, it has received from Professor Mohn the name of King Charles Land, which is now generally accepted. The wide strait which separates it from Spitzbergen is called Olga Strait. It is now established that Gillis saw Gillis's Land to the north-east of the archi-

pelago, and this land, which may perhaps be a link between the Spitzbergen archipelago and that of Franz-Josef, has been again sighted by Norwegian seal-hunters. Numerous small islands lie around the larger—the Danes and Norwegians Islands on the north-west, the Seven Islands on the north, Outger Reps, Brock, and Charles XII Island on the north-east, Waygat Islands and William I. Island in Hinlopen Strait, the Ryk Yse Archipelago, Hope Island, and the Thousand Islands (about a hundred small rocks) to the east and south of Stans Foreland, and many other smaller ones. Many of these small islands rise to a height of 1500 to 1700 feet.¹

The archipelago, which has the Greenland Sea to the west and Barents Sea to the east, rises from a submarine platform that extends from Bear Island north-eastwards to Franz Joseph Land, and probably was an immense arctic continent connected with Greenland during the middle of the Tertiary period. The sea around Spitzbergen has a depth of less than 100 fathoms. Owing to this circumstance the ice readily accumulates round the shores, and, although the glaciers of Spitzbergen do not give origin to icebergs so huge as those of Greenland, the smaller icebergs and the pack-ice are thick enough to prevent access to the shores except for a few months in the year. Happily the Gulf Stream, which washes the shores of Norway, after sending a branch to the east, flows north to the western shores of Spitzbergen, moderating its climate, and leaving an open passage which permits whalers to approach the western coast even under the most unfavourable conditions of ice in the arctic regions. Drift-wood brought from lower latitudes, glass-floats of the Norwegian fishermen, and even the large seeds of the *Entada Gigalobum*, carried by the Gulf Stream from the Gulf of Mexico, are found at the northern extremity of Spitzbergen. On the other hand, a cold current charged with ice descends from higher latitudes along the eastern coast, rendering approach extremely difficult. On this account King Charles Land remained unknown until 1872, and the eastern coast of North-East Land still continues unexplored.

Owing to the warm current, the climate of Spitzbergen is less severe than in the corresponding latitudes of Greenland and Smith Sound. The isotherm of 23° Fahr (−5° C), which crosses the middle of Eastern Siberia, touches its southern extremity, and only the north east coasts of West Spitzbergen and North East Land have an average yearly temperature so low as 14° to 10° 5 (−10° to −11° 9 C). At Mussel Bay (79° 53') the average yearly temperature is 16° (January 14° 1, July 39° 3). Bear Island, notwithstanding its more southerly position, has a lower temperature, as the Gulf Stream does not touch it. Even in the coldest months of the winter a thaw may set in for a few days, but, on the other hand, snow sometimes falls in July and August. Spring comes in June, the snow becomes saturated with water and disappears in places, and scrubby grass and the polar willow open their buds. By the end of June the thermometer has ceased to sink below the freezing point at night, July, August, and September are the best months. In September, however, autumn sets in on shore, though the whalers continue cruising until the end of the month and even reach the highest latitudes. By the end of September the pack ice rapidly freezes into one solid mass. To move on this mass, however, is exceedingly difficult, for the ice, owing to its contraction and expansion, is either intersected by large fissures or broken up and piled into heaps, which puts insuperable difficulties in the way of sledge expeditions.

Glaciers are largely developed. On the high grounds the snow Glac under a level of from 1200 to 1500 feet disappears every year, but on the plateaus it continually accumulates, so as to cover them with an immense ice sheet, like that of Greenland, which slowly discharges by the valleys towards the sea in the form of immense glaciers. All North East Land and the interior of West Spitzbergen are covered with such ice sheets, which descend to King's

¹ Bear Island, half way between the North Cape and Spitzbergen, can hardly be reckoned to the Spitzbergen archipelago. It was formerly renowned for its hunting grounds, but is very seldom visited now. Lying outside the course of the Gulf Stream, it is almost entirely ice bound.

Bay by a glacier 15 miles wide, or by that already alluded to in North East Land, where the ice cliffs are from 200 to 400 feet high. These glaciers, however, discharging into comparatively shallow waters, do not produce such icebergs as those of Greenland. The glaciers of the present epoch are but trifling in comparison with what they were during the Glacial period, when the entire country was buried under an ice sheet, which probably connected all the archipelago into one ice bound continent and spread far beyond to northern Europe.

Geology. The backbone of the islands consists of thick layers of granite, gneiss, and other archaic schists. But more recent formations bearing witness to a much more general climate are not wanting. The Carboniferous period is represented by extensive coal bearing strata, the lowest of which are intermediate with the Devonian (Lofö Bay strata). The Trias, also containing a rich fossil flora, is represented by black clay slate. The Jurassic deposits are widely spread, they mostly belong to the Kelloway, and many of them are coal bearing. To the same period belong the frequently occurring layers of what was formerly called hypersthene, but has now been proved to be (according to Zirkel's classification) diabase and dolerite. The most interesting formation is, however, the Miocene. At a period close, geologically speaking, to the subsequent Glacial period, and even to our own, Spitzbergen was covered with a luxuriant vegetation the like of which is now found only in the 60th parallel in Scandinavia. The shores of Bel Sound, Ice Fjord, and Cape Starostine in 78° N lat were covered with extensive peat bogs, on the edges of which the marsh cypress flowered, dropping its leaves and blossoms into the marshes. Sequoia, poplars, birches, planes, and large oaks also grew there, while in the thick under wood freely developed under their shadow, and thousands of insects swarmed in the thicket. The most striking feature of this Miocene vegetation—a feature conclusively established by the researches of Oswald Heer—is that Spitzbergen, Greenland, Franz-Josef Land, and Nova Zembla were at that time parts of one immense continent, thus realizing the very conditions for the coldest climate, if climate had to depend on telluric causes only. Heer has shown, moreover, in a manner that hardly admits of doubt that the luxuriant vegetation so unmistakably borne witness to by the Miocene strata of the arctic regions could not have developed had it been condemned to endure the long arctic night it now undergoes. This feature of the arctic Miocene flora is unexplained, and will remain so until higher cosmical laws are formulated to explain changes of climate. A change in the position of the earth's axis of rotation (recently the subject of a serious discussion in England and on the Continent) would seem to be the only adequate hypothesis by which to account for the warm vegetation of the period in question in such proximity to the pole, but this hypothesis would be so much at variance with the present state of our knowledge that we may well hesitate to advance it. A brief recurrence of a warmer climate—not nearly so warm as the Miocene, yet somewhat warmer than the present—was also experienced by Spitzbergen after the long period of glaciation as is proved by the occurrence of beds with mussels, which are now found only in much warmer latitudes. This warmer Post Glacial period—traces of which have been met with throughout the arctic and subarctic regions—was followed by a period of slow upheaval, which still continues.

Flora. The flora is of course poor. The only tree is the polar willow, which does not exceed 2 inches in height and bears a few leaves not larger than a man's finger nail, and the only bush is the crowberry (*Vaccinium myrtillus*), to which the recently discovered cloudberry (*Rubus Chamemorus*) may be added. But at the foot of the warmer cliffs some loam has been formed notwithstanding the slowness of putrefaction, and there, in contrast with the brownish heaths that cover the hills, grows a carpet of mosses of the brightest green, variegated with the golden yellow flowers of the ranunculus (*Ranunculus repens* and *hyperboreus*), the Silene, the reddish heads of the *Pedicularis*, the *Oxuria reniformis* (a foot high), the large leaved scurvy grass (*Cochlearia frutescens*), several saxifrages, *Cerastium alpinum*, *Potentilla emarginata*, fox tail grass (*Alopecurus alpinus*), *Dryas octopetala*, *Poa annua*, *pratensis*, and *stricta*, with a few large flowered *Polygona* and *Androsace*, while on the driest spots yellow poppies and nuttall grasses (*Draba*), *Cardamine bellidifolia*, several *Dryas*, &c., are found. Even on the higher slopes, 1500 feet above the sea, the poppy, *Linum hyperboreum*, and *Stellaria edicardii* are occasionally met with. Mosses, mostly European acquaintances, cover all places where peat has accumulated. The slopes of the crags and the blocks of stone on the beach are sometimes entirely covered with a luxuriant moss and lichen vegetation, among the last being the so called "famine bread" (*Umbilicaria arctica*), which has maintained the life of so many arctic travellers. Flowering plants are represented by as many as ninety six species, of which eighty one grow in Greenland and sixty nine in Scandinavia, forty three species are alpine cosmopolites, and have been met with on the Himalayas. The ferns are represented by two species.¹ Although thus limited in number, the flora is suggestive

in its distribution. The vegetation of the south has a decidedly Lappish or European alpine character, while that of the north coast is decidedly American, and recalls that of Melville Island. Many flowering plants which are common in north west Spitzbergen are absent from the east coast, where the cold current is inimical to both flora and fauna, but, on the other hand, one moss (*Pottia hyperborea*) and one lichen (*Usnea melanantha*) are found there which are of American origin and grow both in North America and on the Cordilleras. Algae are most numerous, many, like the brown *Laminaria* and *Nostoc commune*, which fill all pools and are the chief food of many birds, being familiar in Europe. *Protococcus* *nielsii* covers the snow with its reddish powder.

The fauna, although not very rich in species, is exceedingly rich in individuals. It includes fifteen mammals, only two of which are terrestrial—the reindeer and the ice fox—besides the usual inhabitant of the arctic regions, the polar bear.² The number of reindeer is really puzzling. In a single summer, or rather in the course of a few weeks, no fewer than from 1500 to 2000 reindeer were killed by hunters for several consecutive years previous to 1868. Much emaciated in June, they grow very fat towards the end of the autumn, after feeding on the mosses. Great numbers are "marked" (that is, have both ears cut at the same height), and the hunters are persuaded that these individuals come from an unknown continent in the north east, where they have been marked by the hand of man. However strange this hypothesis, it must be acknowledged that the objections urged against it by the Swedish explorers are not conclusive, and that frost bits attacking young calves could hardly account for the symmetrical markings on both ears. The immense numbers of the reindeer strongly support the idea of their migration, and the only question is whether they came from Siberia via Nova Zembla, or whether they did not really come from the unknown archipelagoes on the north east, the existence of which is supported by so many other data (immobility of the ice to the east of Spitzbergen, dirty ice, birds met with off North East Land, as well as several other considerations of a more general character).

Eight Cetaceans are met with in the seas off Spitzbergen, viz.,—*Balanoptera boops*, 80 to 110 feet long, *B. gigas* and *B. rostrata*, 30 feet long, the white whale (*Beluga caudon*), three species of seals (*Phoca barbata*, *granlandica*, and *hyemalis*), and the walrus (*Trichechus* or *Odobenus rosmarus*). The Greenland whale has completely disappeared in consequence of the great havoc made during the last two centuries according to Scoresby, no less than 57,500 individuals were killed between 1660 and 1775. A perfectly reckless extermination of seals is still going on. Notwithstanding walrus tumble about in the water, or lie in crowds on the floating ice, and their number further increases when the flocks of Greenland seals arrive in August.

Birds visit the archipelago in such vast flocks that the cliffs are literally covered with them. The sabbard petrel (*Procellaria glacialis*)—a herald of polar regions—meets the ships approaching Spitzbergen far away from the coasts. Its colonies cover the cliffs, as also do those of the glaucous gull (*Larus glaucus*), or the "burgo master" Rotches (*Mergulus alba*), black guillemots (*Uria grylla*), ivory gulls (*Larus ibicinus*), auks, and kittiwake gulls (*Larus tridactylus*) breed extensively on the cliffs, while geese, loons, and snipe swarm on and about the lagoons and small freshwater ponds. The bernacle goose (*Anser bernicla*) is only a bird of passage, as it goes farther north-east to nest. The eider breeds in large colonies on the islands, where its young are safe from the ice fox, only the glaucous gull and the brent goose (*Bernicla brenta*) being admitted to keep them company, while the lummo (*Alcedo arctica*) and the tern confine themselves to separate cliffs. These birds, however, are only guests in Spitzbergen, the snow bunting (*Emberiza nivalis*) being the only species which stays permanently, twenty three species breed regularly on Spitzbergen, and four others (the falcon, snowy owl, swan, and skua) come occasionally.

There are twenty three species of fishes, but no reptiles. Insects are few. *Lepidoptera* (one species), *Neuroptera* (one), *Hymenoptera* (four), and *Diptera* (twenty) have been met with by the Swedish expeditions. Arachnids, and especially Pantopods, on the other hand, are very common. Molluscs are also very numerous, embracing no less than 130 species. In June several *Limacinae* are met with in such numbers on the coast and at the mouth of the glacier streams as to constitute the chief food of the gulls. At some places the mussels and univalves reach a comparatively colossal size and appear in incredible abundance. Of Crustaceans no fewer than 100 species have been recognized in the waters of the archipelago.

The marine fauna is exceedingly rich in the bluish warmer waters of the Gulf Stream, and the dredgings of the Swedish expeditions, which were prosecuted even under the ice, never failed to bring to the surface a rich variety of remarkable or new forms. From a depth of 8400 feet the "bull dog" machine lifted mud of a tempera-

as follows.—Rosaceae, 7 species, Saxifrages 10, Cruciferae, 15, Ranunculaceae, 8, Sileneae and Alsineae 12, Salix 2, Compositae, 6, Scrophulariaceae, 2, Ericaceae, 2, Gramineae 23, Cyperaceae, 12, Juncaceae 6, Fritillae (Fritillae), 2, Lycopodiaceae 1. The whole of this flora immigrated during the Post-Glacial period, which was warmer than the present.

² The existence of the *Arctica hudsonia* is not quite proved.

¹ According to Mr. Nathorst's researches in 1882 (Sv. Vetenskaps Akad. Handl. Unga, xx. Botanisches Jahrbuch, iv), the flora of Spitzbergen is composed

ture of 33° Fahr (0° 3 C) charged with Radiolarians, *Polythalamæ*, *Globigerinæ*, *Biloculina*, *Dentalia*, and *Nonionina*, together with some Annelids (*Spiochaetopterus* and *Cirratulus*), two Crustaceans (*Cuma rubicunda* and *Apseudes*), one Mollusc, two *Holothuræ*, one *Cephyrea*, and one Sponge. Even at a depth of 15,900 feet animal life was found in unexpected profusion, the mud consisting almost entirely of brown and white *Foraminifera*, among them one Crustacean (a species of *Cuma*). But marine life is much poorer on the east coast, resembling that of Greenland.

Man does not live on Spitzbergen, and the attempts of the Swedes to winter there have for the most part proved failures, except in the case of the "Sofia" expedition, which succeeded in wintering without great loss, though not without suffering from scurvy. None but the Russian "Pomor" (inhabitants of the Murman coast) have succeeded in enduring the arctic winters. The patriarch of Spitzbergen, the Pomor Staraschin (Starostine), spent no less than thirty-two winters (fifteen being consecutive) on the islands, dying of old age in 1826. There was a time in the 17th and 18th centuries when thousands of Dutch, Danes, and others were attracted to Spitzbergen by the whale fishing. Whole villages sprang up on the shores, the best being that of the Dutch—Smeerenberg—which is said to have been visited by 18,000 men in a single summer. The "right whale" having disappeared, the whalers ceased to visit Spitzbergen, and only quite recently an attempt has been made to renew the pursuit of the *Balaenoptera boops*. The chief object of pursuit is the walrus, carried on by Norwegians, sea birds and deer are also occasionally sought.

History
Expeditions

History—Spitzbergen was discovered in 1596 by William Barents, and his companion, Cornelius Ruy, is believed to have circumnavigated the archipelago. Nevertheless it was long considered as a part of Greenland, and described under the names of East Greenland, Nowland, King James's Land, until the old name of Spitzbergen gained the ascendancy. But long before Barents discovered it the Russians had known it under the name of Grumant (a word of unknown origin), and when Chancellor arrived at Archangel in 1553 he learned that the Russians visited Grumant for hunting purposes. After the 17th and 18th century whalers, the Russians began to visit the group, chiefly for walrus, seals, foxes, reindeer, bears, and birds; their huts and crosses are met with at very many places on the coast. Many wintered for several consecutive winters. Since 1830 their visits have almost ceased. The Norwegians began to visit the archipelago about 1795, and their small vessels now visit the Spitzbergen waters in considerable numbers. In 1822 a party wintered successfully, but later attempts have for the most part proved fatal on account of scurvy. To these experienced arctic navigators—assisted by Norwegian *savants*—we are indebted for so many important discoveries in the Barents, Kara, and Siberian Seas.

Several expeditions have made Spitzbergen their base in attempts to reach the north pole. The Russian admiral Tchitchagoff visited it twice, in 1765 and 1766, and reached 80° 28' N lat. John Phipps mapped the north of Spitzbergen in 1773, and reached 80° 48' N lat. In 1818 Buchan and Franklin reached 80° 34' to the north of the archipelago. Clavering and Sabine in 1823 explored the islands, and Sabine made his remarkable magnetic observations, while Clavering reached 80° 20' N lat. Parry, shortly after his return from his third voyage, went to Spitzbergen and reached 82° 44' N lat. on sledges. In the same year the Norwegian geologist Keilhau visited the group and has related his experiences in a remarkable book, *Nær i Ost og Vest Finmarken*. The Swedish professor Lovén was the first to undertake, in 1857, dredging and geological explorations in Spitzbergen and its vicinity. Next year a body of French, Swedish, Danish, and Norwegian naturalists, among whom was Charles Martins, visited the western coast. From 1858 onwards the archipelago has been the object of a series of scientific expeditions. At the suggestion of Lovén, Otto Torell, accompanied by Nordenskjöld and Quennerstedt, opened the series, making many important observations and bringing home rich geological collections. In 1861 a larger expedition led by Torell, Nordenskjöld, Malmgren, Chydenius, and Petersen set out with the object of finding how far it was possible to obtain a measurement of an arc of meridian of sufficient extent. This aim was only partly accomplished, but the expedition returned with an invaluable stock of various observations. The work of the measurement of the arc was completed in 1864 by another expedition conducted by Nordenskjöld, assisted by Malmgren and Dunér, who returned again with a vast number of new and important observations. This expedition was followed in 1868 by that of the "Sofia," under Nordenskjöld, having on its scientific staff Holmgren, Malmgren, and F. Smitt, zoologists, Berggren and Fries, botanists, Lemström, physicist, and Nauckhoff, geologist. They were prevented by ice from getting higher than 81° 42' N lat., but, to use Oswald Heer's words, the expedition "achieved more and gave a wider extension to the horizon of our knowledge than if it had returned merely with the information that the 'Sofia' had hoisted her flag on the north pole." In 1870 two young Swedish savants, Nauckhorst and Wilander, visited Spitzbergen in order to examine the phosphoric

deposits, and two years later a colony was formed in Ice Fjord, and a small railway constructed to work the beds. The attempt, however, did not prove successful. Mr Leigh Smith and the Norwegian Captain Ulve visited and mapped parts of East Spitzbergen in 1871, returning with valuable information. They reached 81° 24' N lat. In the same year Mr Lamont visited the archipelago. In 1872 a great polar expedition set out to winter on Spitzbergen with the intention of attempting in the spring to advance towards the pole on sledges drawn by reindeer. But the expedition encountered a series of misfortunes. The ships were beset in the ice very early in Mussel Bay, and, six Norwegian fishing vessels having been likewise overtaken and shut in, the expedition had to feed the crews on its provisions and thus to reduce the rations of its own men. The reindeer all made their escape during a snow storm, and, when the sledge party reached the Seien Islands, they found the ice so packed that all idea of going north had to be abandoned. Instead of this, Nordenskjöld explored North-East Land and crossed the vast ice sheet which covers it. The expedition returned in 1873 with a fresh store of important scientific observations, especially in physics and submarine zoology. In 1873 Drasche, the geologist, paid a short visit to Spitzbergen, and the Dutch polar expedition approached it in 1882. In 1882 the Swedish geologists Naathorst and De Geer made a journey to which we are indebted for most interesting data about the flora of the islands. In the same year a polar meteorological station was established at Cape Hordsen for carrying on the observations desired by the international polar committee. The year 1883 being very favourable, the Norwegian walrus hunters Andreassen and Johannessen pushed to the north-east of Spitzbergen and discovered new land to the north-east of the archipelago apparently extending as far as 39° E. long.

Bibliography—The literature of the subject is very voluminous, and for full bibliographical details reference must be made to such works as Chydenius's *Svenska Expeditionen till Spetsbergen*, translated into German by Passarge (Jena, 1860), A Leslie's *Arctic Voyages of A. E. Nordenskjöld* (London, 1879), and Chydenius's *Bibliographie der Polar Regionen*, 1878. The earliest maps of Spitzbergen up to 1864 have been reprinted in a Dutch publication (*Tijdschrift van het Aardrijkskundig Genootschap te Amsterdam*, pt. III), it contains the maps of 1690, 1692, 1693, 1694, 1695, and so on. *Petermann's Mittheilungen*, with *Ergänzungshefte*, the *Geographische Jahrbücher*, the *Immer Journal* of the Swedish Geographical Society, and the *Journal of the Roy. Geog. Society* contain more or less detailed accounts of all the Swedish expeditions up to date. The scientific results of the Swedish expeditions are embodied in very many papers, amounting to from 6000 to 7000 printed pages, reference to which will be found in the above mentioned works and periodicals. Oswald Heer's *Flora Fossile Arctica* deserves special mention. Every volume of the memoirs and proceedings (*Handlingar* and *Förhandlingar*) of the Swedish Academy of Sciences contains some remarkable contributions to our scientific knowledge of the far north, and the same can be said of many volumes of the Christiania Academy of Sciences and the Swedish Geological, Botanical, and Zoological Societies. (P. A. K.)

SPLEEN See VASCULAR SYSTEM. For diseases of the spleen, see PATHOLOGY, vol. xviii p. 376 sq., also MALARIA and WOOL-SORTER'S DISEASE.

SPOHR, LUDWIG (1784-1859), violinist and composer, was born at Brunswick on 25th April 1784, but spent his childhood at Seesen, where in 1789 he began to study the violin, and worked so industriously that at six years old he was able to take the leading part in Kalkbrenner's trios. He received his general education at the Brunswick grammar-school,—taking lessons on the violin from Kunisch and studying composition under Hartung. The little he learned from the last-named professor was the only theoretical instruction he ever received, for, as he himself tells us, he taught himself to compose by studying the scores of Mozart. After playing a concerto of his own at a school concert with marked success, he was placed for a time under Maucourt, the leader of the duke's band, and so rapid was his progress that in 1798 he was able to start on his first artistic tour. This proved a failure, but on his return to Brunswick the duke gave him an appointment in his band, and defrayed the expense of his future education under Franz Eck, in company with whom he visited St Petersburg and other European capitals. His first violin concerto was printed in 1803. In that year Spohr returned to Brunswick and resumed his place in the duke's band. A visit to Paris was prevented by the loss of his favourite violin,—a magnificent Guarnerius, presented to him in Russia. Having played in Berlin, Leipsic, Dresden, and other German towns, his increasing reputation gained for him in 1805 the appointment of leading violinist at the court of the duke of Gotha. Soon after this he married his first wife, Dorette Scheidler, a celebrated harpist. At Gotha he composed his first opera, *Die Prüfung*, but did

not succeed in placing it on the stage. *Alma* was equally unfortunate, though it was rehearsed with approval at Weimar in 1808. During this year Spohr accomplished one of the most extraordinary musical exploits on record. Hearing that Talma was performing at Erfurt before the reigning princes assembled for the famous congress, and failing in his attempt to obtain admission to the theatre, he bribed a horn-player to send him as his deputy, and, though he had never touched a horn in his life, he learned in a single day to play it so well that in the evening he was able to fulfil his self-imposed duty without exciting suspicion or remark. Spohr's third opera, *Der Zweikampf mit der Geliebten*, written in 1809, was successfully performed at Hamburg in the following year. In 1811 he produced his (first) *Symphony in E♭*, and in 1812 composed his first oratorio, *Das jüngste Gericht*.¹ It was while employed in the preparation of this work that he first felt the inconvenience inseparable from an imperfect theoretical education, and, with characteristic energy, he set about the diligent study of Marpurg's *Abhandlung von der Fuge*.

In 1812 Spohr visited Vienna, where his splendid violin-playing created a profound sensation, and he was induced to accept the appointment of leader of the orchestra at the Theater an der Wien. He then began the preparation of his greatest dramatic composition, *Faust*, which he completed in 1813, though it was not performed until five years later. His strength as a composer was now fully developed, and the fertility of his imagination enabled him to produce one great work after another with astonishing rapidity. He resigned his appointment at Vienna in 1815, and soon afterwards made a tour in Italy, where he performed his eighth violin concerto, the *Scena Cantante nello Stile Drammatico*,—the finest of his compositions for his favourite instrument. The performer was described by the leading critics of the country as "the finest singer on the violin that had ever been heard." On Spohr's return to Germany in 1817 he was appointed conductor of the opera at Frankfurt, and in that city in 1818 he first produced his dramatic masterpiece, *Faust*. The favour with which this was received led to the composition of *Zemire und Azor*, a romantic piece founded on the story of *Beauty and the Beast*, which, though by no means equal to its predecessor in merit, soon attained a much higher degree of popularity. There can, indeed, be no doubt that *Faust* suffered from the very first from the weakness of its miserable libretto. Had the words been worthy of the music *Faust* would have taken rank among the finest German operas in existence.

Spohr first visited England in 1820, and on 6th March played his *Scena Cantante* with great success at the first Philharmonic concert. At the third he produced a new *Symphony* (No 2) in D minor, written expressly for this occasion, which is remarkable as the first on which the conductor's baton was used at a concert of the Philharmonic Society. Spohr's new symphony met with an enthusiastic reception, as did the earlier one (No 1, in E♭), which was played, together with his *Nocturno*, at the last concert of the series. Indeed he had a triumphant success both as composer and as virtuoso, and he on his side was delighted with the performances of the Philharmonic orchestra. Before leaving London he gave a farewell concert, at which Madame Dorette Spohr played on the harp for the last time. Her health at this period was so delicate that she was recommended to exchange her favourite instrument for the less fatiguing pianoforte, and Spohr, with his accustomed facility, wrote a number of pieces for pianoforte and violin, which the husband and wife played

together with perfect artistic sympathy. After supplementing his visit to England by a short sojourn in Paris, Spohr returned to Germany and settled for a time in Dresden, where German and Italian opera were flourishing side by side under the direction of Weber and Morlacchi. His artistic relations with the composer of *Der Freischütz* were not altogether satisfactory, nevertheless Weber did not hesitate to recommend him strongly to the elector of Hesse Cassel as "kapellmeister." Spohr entered upon his duties at Cassel on 1st January 1822, and soon afterwards began the composition of his sixth opera, *Jessonda*, which he produced in 1823. This work—which he himself always regarded as one of his best productions—marks an important epoch in his career as a dramatic composer. It was the first opera he ever wrote with accompanied recitative throughout in place of the usual spoken dialogue, and by a remarkable coincidence it was produced in the same year as Weber's *Euryanthe*, a work characterized by the same departure from established custom. Unhappily Weber's early death prevented him from making a second essay in the same direction, but Spohr consistently carried out the idea in his later operas, and always with marked success.

Spohr's appointment at Cassel gave him the opportunity of bringing out his new works on a grander scale and with more careful attention to detail than he could have hoped to attain in the service of a less generous patron than the elector. And he never failed to use these privileges for the purpose of doing justice to the works of other composers. Soon after his instalment in his new office Mendelssohn, then a boy of thirteen, visited Cassel with his father, notwithstanding the disparity of their years, a firm and lasting friendship sprang up between the rising genius and the already famous composer, which ceased only with Mendelssohn's death in 1847, and in other similar cases Spohr always proved himself ready to appreciate and foster the talent displayed by others, though it must be admitted that as a critic he was very difficult to please. The success of *Jessonda* led him to produce in 1825 a seventh opera—*Der Berggeist*—founded upon the old German legend of Ribezahl, the ruling spirit of the Riesengebirge. Though less popular than its predecessor, this fine work attained a very fair success. But a far greater triumph awaited the composer at the Rhemish musical festival held at Dusseldorf in 1826. On this occasion his oratorio *Die letzten Dinge* met with so enthusiastic a reception that it had to be repeated a few days later for the benefit of a charity. This work, known in England as *The Last Judgment*, is undoubtedly the greatest of Spohr's sacred compositions, and is remarkable as the first oratorio in which the romantic element is freely introduced, with marked success throughout, and without detriment either to the solemnity of the subject or the sobriety of style which has always been regarded as an indispensable characteristic of sacred music of the highest order. In 1827 Spohr produced his eighth opera, *Pietro von Abano*, the plot of which depends for its chief interest upon the resurrection by the famous necromancer of a lady long since dead and committed to the tomb. The work met with a fair, though not a lasting, success, and the same may be said of a much finer opera, *Der Alchimist*, produced in 1830. Spohr's next publication was of a very different character. His *Violin School*, produced in 1831, is so useful as a code of instruction for advanced students that there is probably no great violinist now living who has not been more or less indebted to it for the perfection of his technique. It holds with regard to the violin a position no less important than that which Cramer's *Studies* has so long held in connexion with the pianoforte.

The year 1833 Spohr spent in the preparation of a new

¹ Literally *The Last Judgment*, but not to be confounded with the oratorio now so well known by that name in England.

oratorio—*Des Heiland's letzte Stunden*, known in England as *Calvary* or *The Crucifixion*—which was performed at Cassel on Good Friday 1835, and sung in English at the Norwich festival of 1839, under Spohr's own direction, with such unexampled success that he was accustomed to speak of this event as the greatest triumph of his life. For the Norwich festival of 1842 he composed *The Fall of Babylon*, which also was a perfect success. His last opera, *Die Kreuzfahrer*, was produced at Cassel in 1845. Of his nine symphonies the finest, *Die Weihe der Töne*, was produced in 1832. His compositions for the violin include concertos, quartets, duets, and other concerted pieces and solos, adapted for the chamber and the concert room, and among these a high place is taken by four double quartets,—a form of composition of which he was both the inventor and the perfecter. He was, indeed, very much inclined to explore new paths, notwithstanding his attachment to classical form, and his freedom from prejudice was proved by the care with which he produced Wagner's *Flying Dutchman* and *Tannhäuser* at Cassel in 1842 and 1853, in spite of the elector's opposition. Spohr retained his appointment until 1857, when, very much against his wish, he was pensioned off. In the same year he broke his arm, but he was able to conduct *Jessonda* at Prague in 1858. This, however, was his last effort. He died at Cassel on 16th October 1859. (W S R)

SPOLETO (Lat. *Spoletum*), a city of Italy, in Umbria, placed in a commanding position near the Via Flaminia, between Rome and Perugia, is said to have been colonized in 240 B.C. (Liv., *Epit.*, xx., Vell. Pat., i. 14), and is called by Cicero (*Pro Balb.*, 21) "colonia Latina in primis firma et illustris." After the battle of Trasimene (217 B.C.) Spoletum was attacked by Hannibal, who was repulsed by the inhabitants (Liv., xxii. 9). During the Second Punic War the city was a useful ally to Rome. It suffered greatly during the civil wars of Marius and Sulla. The latter, after his victory over Crassus, confiscated the territory of Spoletum and reduced it to the rank of a military colony. Under the empire it again became a flourishing town (Strabo, v. p. 227, Plin., *H.N.*, iii. 14, Ptol., iii.

1, 54). Owing to its elevated position it was an important stronghold during the Vandal and Gothic wars, its walls were dismantled by Totila (Procop., *Bell. Get.*, iii. 12). Under the Lombards Spoleto became the capital of an independent duchy (from c. 570), and its dukes ruled a considerable part of central Italy. Together with other fiefs, it was bequeathed to Pope Gregory VII. by the empress Matilda, but for some time struggled to maintain its independence. In 1881 it had a population of 7969 (commune, 21,507), many of whom are occupied in the weaving of woollen stuffs. It is the seat of an archbishopric for the three dioceses of Spoleto, Bevagna, and Trevi.

The city contains many interesting ancient remains,—traces of an early polygonal wall, a Roman theatre, and parts of three temples, built into the churches of S. Agostino, S. Andrea, and S. Giuliano. Remains of a fine Roman bridge were found a few years ago buried in the former bed of a torrent, which now runs along a different line. These remains have recently been buried again under a newly made road. On the citadel, which commands the town, still stands an ancient castle, originally built by Theodoric. This castle was mostly destroyed by the Goths, but was afterwards rebuilt and enlarged at many different times, especially by Pope Nicholas V. The existing building contains work of many different dates. The cathedral of S. Maria Assunta dates partly from the time of the Lombard duchy, but was much modernized in 1644. Over the main entrance is a very interesting and large mosaic of Christ in Majesty signed "Salsernus," 1207, at the sides are figures of the Virgin and St. John. In the choir and on the half cupola of the apse are some of the finest frescoes of Lippo Lippi, representing scenes from the life of the Virgin. Lippo died in 1469, leaving part of the work to be completed by his assistant Fra Diamante. The fine stalls and panelling in the choir are attributed to Bramante. The church of S. Pietro is a fine early example of Lombard architecture, though much modernized. The façade is remarkable for its rich sculptured decorations of grotesque figures, dragons, and foliage. S. Domenico is a fine example of later Italian Gothic with bands of different coloured stones. The three apsed crypt of the church of S. Gregorio is of great interest, it probably dates from the founding of the church in the 9th century. S. Niccolò is a beautiful example of Pointed Gothic.

The city is still supplied with water by a grand aqueduct (see vol. ii. pl. IV.) across the adjacent gorge, it has stone piers and brick arches, and is about 208 feet high and 676 feet long. It is said to have been built in 604 by Theodelapius, the third Lombard duke, and the stone piers belong probably to that time. The brick arches are later restorations.

S P O N G E S

THE great advance which has been made during the past fifteen years in our knowledge of the sponges is due partly to the vivifying influence of the evolutionary hypothesis, but still more to the opportunities afforded by novel methods of technique. To the strength and weakness of the deductive method Haeckel's work on the *Kalkschwämme* (6)¹ is a standing testimony, while the slow but sure progress which accompanies the scientific method is equally illustrated by the works of Schulze (20), who by a masterly application of the new processes has more than any one else reconstructed on a sure basis the general morphology of the sponges. In the general progress the fossil sponges have been involved, and the application of Nicol's method of studying fossil organisms in thin slices has led, in the hands of Zittel and others (24, 35), to a complete overthrow of those older classifications which relegated every obscure petrification to the fossil sponges and consigned them all to orders no longer existing. But, whilst many problems have been solved, still more have been suggested. An almost endless diversity in details differentiates the sponges into a vast number of specific forms, the exclusive possession in common of a few simple characters closely unites them into a compact group, sharply marked off from the rest of the animal kingdom.

¹ These numbers refer to the bibliography at the end of the article.

Structure and Form

Description of a Simple Sponge—As an example of one simple of the simplest known sponges we select *Ascetta primordialis* (fig. 1), Haeckel. This is a hollow vase-like sac closed at the lower end, by which it is attached, opening above by a comparatively large aperture, the *osculum* or vent, and at the sides by numerous smaller apertures or pores, which perforate the walls. Except for the absence of tentacles and the presence of pores it offers a general resemblance to some simple form of *Hydrozoan*. Histologically, however, it presents considerable differences, since, in addition to an endoderm and an ectoderm, a third or mesodermic layer contributes to the structure of the walls, and the endoderm consists of cells (see fig. 21g) each of which resembles in all essential features those complicated unicellular organisms known as choanoflagellate *Infusoria* (see PROTOZOA, vol. xix p. 858). With this positive character is associated a negative one: nematocysts are entirely absent. The activity

FIG. 1.—*Ascetta primordialis*, Hk. After Haeckel.

of the *Ascetta*, as of all sponges, is most obviously manifested, as Grant (5) first observed, by a rapid outflow of water from the oscule and a gentle instreaming through the pores,—a movement brought about by the energetic action of the flagella of the endodermic cells. The instreaming currents bear with them into the cavity of the sac (paragastric cavity) both protoplasmic particles (such as *Infusoria*, diatoms, and other small organisms) and dissolved oxygen, which are ingested by the flagellated cells of the endoderm. The presence of one or more contractile vacuoles in these cells suggests that they excrete water, urea, and carbonic acid. The insoluble residue of the introduced food, together with the fluid excreta, is carried out through the oscule by the excurrent water. New individuals are produced from the union of ova and spermatozoa, which develop from wandering amoeboid cells in the mesoderm. The walls of *Ascetta* are strengthened by calcareous scleres, more especially designated as spicules, which have the form of tri-radiate needles. If we make abstraction of these we obtain an ideal sponge, which Haeckel has called *Olynthus* (6), and which may be re-

FIG 2.—*Homoderma sycandra*, Lfd. One half cut away by a vertical median section. After V. Lendenfeld (x about 1).

FIG 3.—*Homoderma sycandra*, Lfd. Transverse section, showing radial tubes opening into central paragastric cavity. After V. Lendenfeld (x about 1).

garded as the ancestral form from which all other sponges have been derived. To give greater exactness to our abstraction we should perhaps stipulate for the *Olynthus* a somewhat thicker mesoderm and more spherical form than a decalcified Ascon presents.

Canal System—We shall now trace the several modifications which the *Olynthus* has undergone as expressed in the different types of canal system.

The simple paragastric of *Ascetta* may become complicated in a variety of ways, such as by the budding off type from a parent form of stolon-like extensions, which then give rise to fresh individuals, or by the branching of the Ascon sac and the subsequent anastomosis of the branches, but in no case, so long as the sponge remains within the Ascon type, does the endoderm become differentiated into different histological elements. The most interesting modification of the Ascon form occurs in *Homoderma sycandra* (12), in which from the walls of a simple Ascon canal processes grow out radiately in close regular whorls, each process reproducing the structure of the parent sponge (figs 2, 3). From this it is but a short step to the important departure which gives rise to the Sycons.

In the simplest examples of this type the characters of Sycon *Homoderma sycandra* are reproduced, with the important exception that the endoderm lining the paragastric cavity of the original Ascon form loses its primitive character,

FIG 4.—*Heteropneustes nodosus*, Pol. Part of a transverse section. The straight lines indicate spicules. The porous surface is upper rim of the branching radial tubes are indicated dark by numerous small circles representing choanocytes. After Polejaeff, "Challenger" Report (x 50).

and from a layer of flagellated cells becomes converted into a pavement epithelium, not in any distinguishable feature different from that of the ectoderm. The flagellated cells are thus restricted to the canal outgrowths or radial tubes. Concurrently with this differentiation of the endoderm a more abundant development of mesoderm occurs. In some Sycons (*Sycon*, Ill.) the radial tubes remain separate and free, in others they lie close together and are united by trabeculae, or by a trabecular network, consisting of mesodermic strands surrounded by ectoderm (fig 1). The spaces between the contiguous radial tubes thus become converted into narrow canals, through which water passes from the exterior to enter the pores in the walls of the radial tubes. These canals are the "inter canals" of Haeckel, now generally known by their older name of *incurrent canals*. The openings of the incurrent canals to the exterior are called pores, a term which we have also applied to the openings which lead directly into the radial tubes, or paragastric cavity, to avoid ambiguity we shall for the future distinguish the latter kind of opening as a *prosopyle*. The term 'pore' will be hereafter

restricted to the sense in which it was originally used by Grant. The mouth by which a radial tube opens into the paragastric cavity is known as a *gastric ostium*. In the higher forms of Sycons the radial tubes no longer remain separate growths of the whole sponge-wall, but rather as out-

oratorio—*Des Heiland's letzte Stunden*, known in England as *Calvary* or *The Crucifixion*—which was performed at Cassel on Good Friday 1835, and sung in English at the Norwich festival of 1839, under Spohr's own direction, with such unexampled success that he was accustomed to speak of this event as the greatest triumph of his life. Structure and Form

Description of a Simple Sponge—As an example of one simple sponge.

of the simplest known sponges we select *Ascuta primordialis* (fig. 1), Haeckel. This is a hollow vase-like sac closed at the lower end, by which it is attached, opening above by a comparatively large aperture, the *osculum* or vent, and at the sides by numerous smaller apertures or *pores*, which perforate the walls. Except for the absence of tentacles and the presence of pores it offers a general resemblance to some simple form of *Hydrozoan*. Histologically, however, it presents considerable differences, since, in addition to an endoderm and an ectoderm, a third or mesodermic layer contributes to the structure of the walls, and the endoderm consists of cells (see fig. 21g) each of which resembles in all essential features those complicated unicellular organisms known as choanoflagellate *Infusoria* (see PROTOZOA, vol. ix, p. 858). With this positive character is associated a negative one: nematocysts are entirely absent. The activity

FIG. 1.—*Ascuta primordialis*, Hk. After Haeckel.

of the *Ascetta*, as of all sponges, is most obviously manifested, as Grant (5) first observed, by a rapid outflow of water from the oscule and a gentle instreaming through the pores,—a movement brought about by the energetic action of the flagella of the endodermic cells. The instreaming currents bear with them into the cavity of the sac (paragastric cavity) both protoplasmic particles (such as *Infusoria*, diatoms, and other small organisms) and dissolved oxygen, which are ingested by the flagellated cells of the endoderm. The presence of one or more contractile vacuoles in these cells suggests that they extricate water, urea, and carbonic acid. The insoluble residue of the introduced food, together with the fluid excreta, is carried out through the oscule by the excurrent water. New individuals are produced from the union of ova and spermatozoa, which develop from wandering amoeboid cells in the mesoderm. The walls of *Ascetta* are strengthened by calcareous scleres, more especially designated as spicules, which have the form of tri-radiate needles. If we make abstraction of these we obtain an ideal sponge, which Haeckel has called *Olynthus* (6), and which may be re-

FIG 2.—*Homoderma sycandra*, Lfd. One half cut away by a vertical median section. After V Lendenfeld (\times about 6).

FIG 3.—*Homoderma sycandra*, Lfd. Transverse section, showing radial tubes opening into central paragastric cavity. After V Lendenfeld (\times about 12).

garded as the ancestral form from which all other sponges have been derived. To give greater exactness to our abstraction we should perhaps stipulate for the *Olynthus* a somewhat thicker mesoderm and more spherical form than a decalcified Aseon presents.

Canal System—We shall now trace the several modifications which the *Olynthus* has undergone as expressed in the different types of canal system.

The simple paragaster of *Ascetta* may become complicated in a variety of ways, such as by the budding off type from a parent form of stolon-like extensions, which then give rise to fresh individuals, or by the branching of the Aseon sac and the subsequent anastomosis of the branches, but in no case, so long as the sponge remains within the Aseon type, does the endoderm become differentiated into different histological elements. The most interesting modification of the Aseon form occurs in *Homoderma sycandra* (12), in which from the walls of a simple Aseon caecal processes grow out radiately in close regular whorls, each process reproducing the structure of the parent sponge (figs 2, 3). From this it is but a short step to the important departure which gives rise to the Sycon.

In the simplest examples of this type the characters of *Homoderma sycandra* are reproduced, with the important exception that the endoderm lining the paragastric cavity of the original Aseon form loses its primitive character,

FIG 4.—*Heteropegma nodus-gordii*, Pol. Part of a transverse section. The straight lines indicate spicules; the poriferous surface is uppermost; the branching radial tubes are rendered dark by numerous small circles representing choanocytes. After Polejaeff, "Challenger Report" (\times 50).

and from a layer of flagellated cells becomes converted into a pavement epithelium, not in any distinguishable feature different from that of the ectoderm. The flagellated cells are thus restricted to the caecal outgrowths or radial tubes. Concurrently with this differentiation of the endoderm a more abundant development of mesoderm occurs. In some Sycons (*Sycalis*, Hk.) the radial tubes remain separate and free, in others they lie close together and are united by trabeculae, or by a trabecular network, consisting of mesodermic strands surrounded by ectoderm (fig 4). The spaces between the contiguous radial tubes thus become converted into narrow canals, through which water passes from the exterior to enter the pores in the walls of the radial tubes. These canals are the "inter-canals" of Haeckel, now generally known by their older name of *incurrent canals*. The openings of the incurrent canals to the exterior are called pores, a term which we have also applied to the openings which lead directly into the radial tubes or paragastric cavity, to avoid ambiguity we shall for the future distinguish the latter kind of opening as a *prosopyle*. The term "pore" will then be

restricted to the sense in which it was originally used by Grant. The mouth by which a radial tube opens into the paragaster is known as a *gastric ostium*. In the lower forms of Sycons the radial tubes no longer arise as simple outgrowths of the whole sponge wall, but rather as out-

of the endoderm into the mesoderm, which, together with the ectoderm, exhibits an independent growth of its own, and this results in the formation of a thick investment, known as the *cortex* (fig 5), to the whole exterior of the

FIG. 5.—*Ulc Argentea* Pol. Part of a transverse section. The concentric circles, indicating transverse sections of spicules, lie within the cortex. After Polejaeff, "Challenger Report" (x100).

sponge. The radial tubes may branch, *Heteropogma* (fig 4). If the branches are given off regularly, as the radial tubes were in the first plan, and if at the same time the original radial tube exchanges its flagellated for a pavement epithelium, a structure as shown in fig 6 (*Polegna*

FIG. 6.—*Polegna connexa*, Pol. Part of a transverse section. E excurrent canals into which the flagellated chambers open. After Polejaeff, "Challenger Report" (x50).

connexa, Pol) will result. This form might also be brought about by unequal growth of the gastral endoderm leading to a folding of the inner part of the sponge-wall. Very little direct evidence exists as to which of these two plans has actually been followed. Phylogenetically the transition from a simple Ascon to the most complicated Sycon can be traced step by step, and ontogeny shows that such a Sycon form as *Grantia raphanus* passes through an Ascon phase in the course of its larval development.

Rhagon type.

Returning to the ancestral form of sponge, *Olynthus*, let us conceive the endoderm growing out into a number of approximately spherical chambers, each of which communicates with the exterior by a prosopyle and with the paragastric cavity by a comparatively large aperture, which we may term for distinction an *apopyle*, at the same time let the endoderm lose its flagellated character and become

converted into a pavement epithelium, except in the spherical chambers. Such a form, called by Haeckel "dyssycus," may be more briefly named a *Rhagon* from the grape-like form of its flagellated chambers, which differ from those of a Sycon both by their form and their smaller dimensions. The Rhagon occurs as a stage in the early development of *Plakina monolopha* (Schulze) and *Reniera fertilis* (p) (fig 7), a calcareous sponge which appears to

FIG. 7.—Vertical section of a Rhagon, partly diagrammatic. o, oscule, p, paragastric. After Keller (x about 100).

approach it somewhat is *Leucopsis pedunculata*, Lfd. By the folding of the wall of a Rhagon, or by its outgrowth into lobes, a complicated structure such as that of *Plakina monolopha* (20) (see fig 26 f) results. This is character-

FIG. 8.—Transverse section across an excurrent canal and surrounding choanosome of *Cyclonema coarctum*, Soll. e, excurrent canal, f, flagellated chambers communicating with it by aphodal canals, i, an incurrent canal cut across, s, a sterraster, o, an oxea cut across. After Sollas, "Challenger Report" (x12).

ized by the chambers retaining their immediate communication with the incurrent and excurrent canals, opening into the latter by the widely open apopyle and receiving the former by one or several prosopyles. This may be termed the *eury-pylous* type of Rhagon canal system. The folding of the sponge-wall may be simple, as in the example given, or too complex to unravel. In higher forms of sponges (*Geodinae*, *Stelletidae*) the chambers cease to open abruptly into the excurrent canals; each is prolonged into a narrow canal, *aphodus*, or *abitus*, which usually directly, sometimes after uniting with one or more of its fellows, opens into an excurrent canal. The prosopyles, now restricted to one for each chamber, may remain unchanged in character or at the most be prolonged into very short

FIG. 9.—Diplodal canal system in *Corticium candelabrum*, O.S. e, excurrent canal, the incurrent canal is shown on the left-hand side near its commencement in the cortex. After T. E. Schulze (x200).

tubes, each a *prosodus* or *aditus* (fig 8) This may be termed the *aphodal* or *racemose* type of Rhagon system, since the chambers at the ends of the aphodi radiating from the excurrent canal look like grapes on a bunch As Haeckel, however, has used "racemose" in a different sense, we shall adopt here the alternative term By the extension of the prosodal or adital canals into long tubes a still higher differentiation is reached (fig 9) This, which from the marked presence of both prosodal and aphodal canals may be termed the *diploidal* type of the Rhagon canal system, occurs but rarely *Chondrosia* is an example

The following scheme will render clear the foregoing distinctions —

- 1 Aseon type simple, ex *Asetta*, Hk, strobiloid, ex *Homoderma*, Lfd
- 2 Sycon type simple radial tubes, ex *Sysetta*, Hk, branched radial tubes (cylindrical chambers), ex *Heteropegma*, Pl, chamber layer folded, ex *Poleyna*, Pol
- 3 Rhagon type euryptous, with several prosopyles to each chamber, ex *Spongia*, with a single prosopyle to each chamber, ex *Oscarella*, *Thenea*, aphodal, aphodal canals well developed, ex *Geodia*, Link, diploidal, with both aphodal and prosodal canals well developed, ex *Chondrosia*, OS

In the case of the calcareous sponges Polejaeff has argued forcibly that the euryptous type arises directly from the Sycon and not from the Rhagon It is therefore doubtful how far the Rhagon in other sponges is a primitive form derived directly from an *Olinthus*, or whether it may not be a secondary larval state resulting from the abbreviated development of a former Sycon predecessor Whatever may have been its past history, the Rhagon serves now at all events as a starting-point for the development of the higher forms of canal system

Subdermal cavities.

In the higher Rhagons, as in the Sycons, further complications ensue, owing to an independent growth of the external ectoderm and the adjacent mesoderm While the endoderm, with its associated mesoderm, is growing out or folding to form the excurrent canal system, the superficial mesoderm increases in thickness, and the ectoderm, extending laterally from the sides of the incurrent sinuses, burrows into it, parallel to the surface of the sponge Thus it forms beneath the skin (i.e., the layer of superficial mesoderm and investing ectoderm) cavities which may be either simple and spacious or be broken up into a number of labyrinthine passages by a network of mesoblastic strands (invested with ectoderm) which extend irregularly from roof to floor of the chamber These cavities are known as *subdermal chambers*

Ectosome, choanosome.

With the appearance of subdermal chambers the sponge becomes differentiated into two almost independent regions, an outer or *ectosome* and an inner or *choanosome*, which is characterized by the presence of flagellated chambers The ectosome forms the roof and walls of the subdermal chambers, and is in its simplest form merely an investing skin, but in a large number of sponges it acquires considerable thickness and a very complicated histological structure It is then known as a *cortex* The thickening which gives rise to a cortex takes place chiefly beneath those parts of the skin which are not furnished with pores Beneath the pores—in this case collected into sieve-like areas—dome-like cavities are left in the cortex, they open freely into the subdermal cavities below and their roof is formed by the eubiform pore membrane above In many sponges (*Geodia*, *Stelletta*) the cortical domes are constricted near their communication with the subdermal cavity (subcortical crypt) by a transverse muscular sphincter, which defines an outer division or *ectochone* from an inner or *endochone* (fig 10), the whole structure being a *chone* The endochone is frequently absent (fig 10) The early development of the cortex has scarcely yet been studied In *Stelletta phrisiensis* (Soll), one of the "Challenger" *Stel-*

lettida, an early form of the sponge (fig 11), shows the choanosome already characteristically folded within the cortex, which forms a complete not-folded envelope around it The roots of the incurrent sinuses form widely open spaces immediately beneath the cortex and are the rudiments of subcortical crypts Again, in some sponges a part of the endoderm and associated mesoderm may likewise develop independently of the rest of the sponge, as in the *Heteractinellida*, where the choanosome forms a middle layer between a reticulation of ectosome on the one side and of endoderm and mesoderm, i.e., *endo-*

soma, on the other Finally, the attached or lower half of a Rhagon may develop in an altogether different manner from the other or upper half, the endoderm not producing any flagellated chambers In this case the upper portion alone is characterized by the flagellated chambers, which are the distinctive mark of a sponge, and hence may be

FIG 10—Section through the cortex of *Cydonium costatum*, Soll, showing the pores above overlying the choanosome, which communicates through a siphonate aperture with the subcortical crypt, lying in the choanosome with its flagellated chambers. The dotted circles in the cortex are sinuasters connected by fibrous strands. After Sollas, "Challenger" Report (x75).

called the *spongomer*, the lower half, which consists of all three fundamental layers, may be called the *hypomer*

The form and general composition of sponges are exceedingly various and often difficult to analyse, presenting, along with some important differences, a remarkable general resemblance to the *Celentera* in these respects Like *Oscula*, them, some sponges are simple, and others, through asexual multiplication, compound The only criterion by which the individual sponge can be recognized is the osculum, and, as it is frequently difficult, and in many cases impossible, to distinguish this from the gastric opening of a large excurrent canal, there are many cases in which the simple or compound nature of the sponge must remain open to doubt The oscule may also fail (*lipostomosis*), and so may the paragastric cavity (*lipogastrosis*), the problem then becomes insoluble The loss of the oscule

Chone

may in some cases be due to the continued growth of several endodermal folds towards the exterior, with a corresponding absorption of the mesoderm and ectoderm which lie in the way, till the folds penetrate to the ectoderm and open at the exterior, thus giving rise to excurrent openings, which are not readily distinguishable from pores. At the same time the original osculum closes up and entirely disappears. Lipogastrosis, on the other hand, may be produced by the growing together of the roots of the choanosomal folds, thus reducing the paragastric cavity to a labyrinth of canals, which may easily be confounded with the usual form of excurrent canals. While in some sponges the original oscule is lost, in others secondary independent openings, deceptively like oscules, are added. Thus pseudostomosis is due to a folding of the entire sponge, so as to produce secondary canals or cavities, which may be incurrent (*resibular*) or excurrent (*cloacal*), the opening of the latter to the exterior being termed a *false oscule* or *pseudostome*. The faulty use of the term oscule for what is neither functionally nor morphologically a mouth is here obvious, for in one sense the oscule is always a pseudostome, it would be better if the term *pseudopore* could be substituted.

Skeleton. *Skeleton*—All sponges, except three or four genera belonging to the *Myrospongiae* possess some kind of skeletal structures. They may be either calcareous or silicious or horny scleres, the latter usually having the form of fibres, which sometimes enclose silicious needles (spicules) or foreign bodies introduced from without. Foreign bodies also contribute to the formation of the skeleton of some silicious sponges, and occasionally form the entire skeleton, no other hard parts being present.

Mineral spicules. *Mineral scleres* usually occur in the form of spicules. The spicules of calcareous sponges consist of carbonate of lime, having the crystalline structure and other properties of calcite (29). Each spicule, so far as its mineral component is concerned, is a single crystal, all the molecules of calcite of which it is built up being similarly oriented. On the other hand, its form and general structure are purely organic. Its surfaces are always curved, and usually it has the form of a cone or combination of cones, each of which consists of concentric layers of calcite surrounding an axial fibre of organic matter,—probably of the same nature as spongin or spongin, the chief constituent of the fibres of horny sponges. A thin layer of organic matter, known as the *spicule sheath*, forms an outer investment to the spicule and is best rendered visible as a residue by removing the calcite with weak acid. Silicious spicules consist of colloid silica or opal, and hence can be distinguished from calcareous by having no influence upon polarized light. Structurally the two kinds of spicules present no important difference. The spicules of different sponges differ greatly both in form and in size. They may be conveniently divided into two groups,—minute or flesh spicules, which usually serve as the support of a single cell only (*microscleres*), and larger or skeletal spicules, which usually contribute to the formation of a more or less consistent skeleton (*megascleres*). The distinction is not one that can be exactly defined, and must so far be regarded as of a provisional nature. There is usually but little difficulty in applying it in practice, except in some doubtful cases where large spicules do not form a continuous skeleton, or in others where flesh spicules appear to be passing into those of larger size. It is indeed highly probable that all large spicules have originated from flesh spicules (12).

(1) *Monaxon Uniradiate Type (rhabdus)*—By far the commonest form is the oxea, a needle-shaped form pointed at both ends and produced by growth from a centre at the same rate in opposite directions along the same axis. It is therefore uniaxial and equiradiate (fig 12a). (2) *Mon-*

axon Uniradiate Type (stylus)—By the suppression of one of the rays of an oxea, an acute spicule or stylus results (fig 12b). (3) *Triaxon Triradiate Type*—Linear growth

FIG. 12.—Typical mesoscleres. a, rhabdus (monaxon diactine), b, stylus (monaxon monactine), c, triad (triatron triactine), d, calthrops (tetraxon tetractine), e, triaxon hexactine, f, desma of an anomoeoladine Lithistid (polyaxon), g, sternaster (polyaxon), h, radial section through the outer part of g showing two actines soldered together by intervening silica, the free ends terminating in recurved spines and the axis traversed by a central fibre.

from a centre in three directions inclined at an angle of 120° to each other gives rise to the primitive form of tri-radiate spicule so eminently characteristic of the calcareous sponges, but by no means confined to them (fig 12c). (4) *Tetraxon Quadriradiate Type (Calthrops)*—Growth from a centre in four directions inclined at about 110° to each other produces the primitive quadriradiate form of the *Tetractinellida* and of some calcareous sponges (fig 12d).

(5) *Serradiate Type*—Growth in six directions along three rectangular axes produces the primitive sexradiate spicule of the *Hexactinellida* sponges (fig 12e). (6) *Multiradiate Type*—Extensions radiating in many directions from a centre produce a stellate form (fig 12f). (7) *Spherical Scleres*—Concentric growth of silica about an organic particle produces the sphere, which occurs as a reduction of the rhabdus in some species of *Pæcillastra*, or as an overgrown globule (flesh spicule) in *Caminus*.

Usually conical, the spicular rays often become cylindrical, usually pointed (*oxate*) at the ends, they are also frequently rounded type off (*strongylate*), or thickened into knobs (*tylostate*), or branched (*cladose*). Their growth is not always rigorously confined to a

FIG. 13.—Modifications of monaxon type. a, strongyle, b, tylostate, c, oxea, d, tylo-oxea, e, tylostyle, f, style, g, spined tylostyle, h, sagittal triad (a triaxon form derived from the monaxon), i, oxytylostate, j, anatrypane, k, protiriane, l, orthotriane, m, dichotriane, n, centro-triiane, o, amphitriane, p, crepidial strongyle (basis of Rhabdocephalid Lithistid desma), q, young form of Rhabdocephalid desma, showing crepidial strongyle coated with successive layers of silica, r, Rhabdocephalid desma fully grown. The dotted line through the upper figures marks the origin of the actines.

straight line frequently they are curved or even undulating. They are also liable to become spined, either by mere superficial thickening or by a definite outgrowth involving the axial fibre (fig 13g, h). The rhabdus if pointed at both ends is known as an *oxea* (fig 13c), if rounded at both ends as a *strongyle* (fig 13a), if knobbed

at both ends as a *tylote* (fig 13 b), the tylote if pointed at one end is a *tylotarxa* (fig 13 d), the strongly similarly becomes a *strongyl oxa*. These last two forms are with difficulty distinguished from the stylus, which is usually pointed at the end, and strongly tylote (fig 13 f) or tylotate (fig 13 c) about the origin. A particular case of the eladose rhabdus, but one of the most frequent occurrences, is the *trirane*, in this form one ray of a rhabdus ends in three branches, which diverge at equal angles from each other. The rhabdus then becomes known as the shaft or *rhabdome*, and the secondary rays are the arms or *cladi*, collectively the head or *cladome* of the spicule. The arms make different angles with the shaft when recurved a grapnel or *anatrane* is produced (fig 13 l), when projecting forwards a *protrane* (fig 13 i), and when extended at right angles an *orthotrane* (fig 13 m). The arms of a triane may bifurcate (*dichotrane*) once (fig 13 n), twice, or oftener, or they may trifurcate. Again, they may extend laterally into undulating lamellae, or unite to form a disk the triane character of which is indicated by the included axial fibre. The shaft may also become trifid at both ends, *amphitrirane* (fig 13 p), and the resulting rays all bifurcate, or the cladome may arise from the centre of the rhabdome, *centrotrirane* (fig 13 o). Amongst one group of Lithistid sponges (*Rhabdocrepida*) the normal growth of a strongyle is arrested at an early stage, it then serves as a nucleus upon which further silica is deposited, and in such a manner as to produce a very irregularly branching sclero or desma (fig 13 s), within which the fundamental strongyle can be seen enclosed. In such a desma no axial fibre besides that of the enclosed strongyle is formed.

The chief modification of the triadial spicule is due to an elongation of one ray, distinguished as *apical*, the shorter paired rays being termed *basal*, and the whole spicule a sagittal triadial. The angle included by the basal rays is usually over 120° (fig 14 a).

Some or all of the rays of the primitive calthrops (fig 14 b) may

FIG 14.—Modifications of the triaxon and tetraaxon types. a, sagittal triadial or triad; b, calthrops; c, candelabra (a polyeladose microcalthrops); d, a spined microcalthrops; e, Tetracladine Lithistid desma.

subdivide into a number of terminal spines *candelabra* (fig 14 c), or some or all of them may bifurcate once or twice and finally terminate by subdividing into numerous variously shaped processes, such a *tetracladine* desma (fig 14 e) characterizes one division of the Lithistid sponges.

By the excess or defect of one or more rays a series of forms such as are represented in fig 15 arise. In the oxa, which results from

FIG 15.—Modifications of the triaxon hexactine type. a, dagger; b, c, two varieties of pinulus; d, amphidial; e, pentactine; f, staurus; g, dermal rhabdus. After Schulze.

the suppression of all rays but two, the sexradiate character is sometimes preserved by the axial fibre, which gives off two or four processes in the middle of the spicule where the defective arms would arise. Let fig 12 c represent a regular sexradiate spicule with its four horizontal arms extended beneath the dermis of its sponge, the over development of the proximal ray and a reduction of the distal ray produce a form known as the *dagger* (fig 15 a), the suppression of the proximal ray and the development of spines projecting forwards on the distal ray produce the *pinulus* (fig 15 b, c), the suppression of both proximal and distal rays gives the *staurus* (fig 15 f), and the suppression of two of the remaining horizontal rays a dermal rhabdus (fig 15 g). The suppression of a distal ray, excessive development of a proximal ray, and recurved growth of the remaining rays produce an *anchor*. In *Hyalonema* (glass rope sponge) anchors over a foot long occur, but their arms or teeth are not restricted to four, and the axial fibre gives off its processes before reaching the head of the spicule. Such a grapnel helps to support the sponge in the ooze of the sea bed. Other character

FIG 16.—a, uncinaria; b, clavula; c, scopularia. After Schulze.

istic spicules belonging to sponges distinguished by sexradiate spicules are the following—the *uncinaria* (fig 16 a), a spinose

oxea with the spines all pointing one way, the *clavula*, a tylotate form with a toothed margin to the head (fig 16 b), the *scopularia* (fig 16 c), a besom shaped spicule with tylotate rays, which vary in number from two to eight, the *amphidial* (fig 15 d), a shaft terminating at each end in a number of recurved rays. When the sexradiate spicules of the *Hexactinellida* unite together in a manner to be described later, the rays may be bent in a variety of ways out of the triaxial type, so that the sexradiate character alone remains.

Multiradiate Type.—The rays of an aster as of other spicules may be spined or tylotate. In one remarkable form known as a radiate *sterraster* (fig 12 g, h), and characteristic of the family *Geodinae*, type. the rays are almost infinite in number, and coalesced for the greater part of their length, the distal ends, however, remain separate, and, becoming slightly tylotate, are produced into four or five recurved spines, which give attachment to connective tissue fibres by which adjacent sterrasters are united together.

In one aberrant group of Lithistid sponges (*Anomocladina*) the skeleton is formed of desmas, which are multiradiate, each presenting a massive centrum (with an included cavity) produced into a variable number (4 to 8) of rays, which rays terminate in expanded ends (fig 12 f).

It is doubtful whether a distinction between megascleres and Microscleres can be maintained in the calcareous sponges, unless scleros the minute oxeas which occur in *Eithardia schulzei*, Pol (16), are to be referred to this group. They are widely distributed throughout the siliceous sponges, and by their different forms afford characters of the highest importance in classification.

One of the simplest forms is the *sigmaspire* (fig 17 a, b), it looks like the letter C or S, according to the direction in which it is

FIG 17.—Microscleres. a, b, sigmaspire viewed in different directions,—a along axis, and b, obliquely; c, toxaspire; d, spiraster; e, sandaster; f, amphiaster; g, sigman or cymba; h, cymba with three pterata at each end,—the central one a proral pteron and the lateral, ploral pteron; j, one end of another form of cymba showing seven pteron; k, monopteral cymba; l, proral pteron only developed at ends, tropidial pteron much enlarged; m, coccymba in which proral and ploral pteron have grown towards each other and coalesced; n, spiraster; o, oxyaster; p, the same with six actines; q, the same with four actines; r, microxela; s, microxela (q, r, and s are reduced asters); t, rosette.

viewed, its actual form being that of a single turn of a cylindrical spiral. A turn and a part of a turn of a spiral of somewhat higher pitch than that of a sigmaspire gives the *toxaspire* (fig 17 c), a continued spiral growth through several revolutions gives the *polyaspire*. The sigmaspire becoming spined produces the *spiraster* or *spinspirula* (fig 17 d), thus, by losing its curvature, becomes the *sandaster* (fig 17 e), and by simultaneous concentration of its spines into a whorl at each end, the *amphiaster* (fig 17 f). By reduction of the spire the spiraster passes into the *stellate* or *aster* (fig 17 n). A thickening about the centre of the aster produces the *spheraster* (fig 17 m), allied to which is the *sterraster*. By a reduction in the number of its rays the aster becomes a minute calthrops, from which, by increased growth, the skeletal calthrops may very well be derived, by further reduction to two rays a little rhabdus or microrabd results, and of this numerous varieties exist, of which the oxeate microrabd is the most interesting, since it only differs in size from the commonest of all skeletal spicules, the oxeate or acerate rhabdus. The sigmaspire is formed as a superficial spiral thickening in the wall of a spicule cell or scleroblast, as superficial deposits also the next group of spicules, the so called *anchors*, arise. Take a hen's egg as the model of a scleroblast, draw round it a broad meridional band, interrupted only on one side, for 30° above and below the equator, this will represent a truly C shaped spicule, which differs from a sigmaspire by the absence of spiral twist. It may be termed a *cymba* (fig 17 g). The back of the "C" is the *keel* or *trapis*, the points are the *prors* or *prora*. Now broaden out the prors on the eggshell into oval lobes (*proral pteron*), and from each pole draw a lobe midway between the prors and the *trapis* (*ploral pteron*), and a common form of anchorate, the *microcymba*

results (fig 17 h). The pterocymba is subject to considerable modifications; the prors may be similar (*homoproral*) or dissimilar (*heteroproral*), the pteres may be lamellar or unguis, additional lamellae (*tropidial pteres*) may be produced by a lateral outgrowth of the keel (fig 17 k), and by growing towards the equator the opposed proral and pleural pteres may conjoin, producing a spicule of two meridional bands (*oocymba*, fig 17 l). A curious group of flesh spicules are the *trichites*. In this group silica, instead of being deposited in concentric coatings around an axial fibre, forms within the scleroblast a sheaf of immeasurably fine fibrillae or trichites, which may be straight (fig 17 m) or twisted. The trichite sheaf may be regarded as a fibrillated spicule. Trichite sheaves form in some sponges, as *Dragmastra* (25), a dense accumulation within the cortex. In Hexactinellid sponges the rays of the aster are limited to six, arranged as in a primitive sexradiate spicule, but divided at the ends into an indefinite number of slender filaments, which may or may not be tylotate, *rosettes* (fig 17 i).

Spongin
scleres

Spongin is a horny substance, most similar to silk in chemical composition, from which it differs in being insoluble in an ammoniacal solution of copper sulphate (cuproso-ammonium sulphate). In *Darwinella aurea*, F. Müller, it occurs in forms somewhat resembling tri-, quadri-, and sex-radiate spicules. But usually the spongin skeleton takes the form of fibres, consisting of a central core of soft granular substance around which the spongin is disposed in concentric layers, forming a hollow cylinder (fig 23 b). The relative diameters of the soft core and of the spongin cylinder differ greatly in different sponges. The fibres branch so as to form antler like twigs or bushy tree like growths, or anastomose to form a continuous network, as in the bath sponge (*Euspongia officinalis*). The detailed characters of the network differ with the species, and are useful in classification. In *Ianthella* certain cells (sponginblasts) become included between the successive layers of the spongin cylinder, and their deep violet colour, contrasting with the amber tint of the spongin, renders them very conspicuous.

In some sponges the scleres are simply scattered through the mesoderm and do not give rise to a continuous skeleton.—*Corticium*, *Chondrilla*, *Thrombus*. In the *Calcarea* and many silicious sponges they are dispersed through the mesoderm, but so immovably that by the overlapping of their rays a loosely felted skeleton is produced. In the calcareous sponges the spicules are frequently regularly disposed, and in the Sycons in particular a definite arrange-

FIG 18.—Articulate and inarticulate tubular skeletons of calcisponges. a, articulate b inarticulate skeleton. After Haeckel.

ment, on two plans, the *articulate* and *inarticulate*, can be traced in the skeleton of the radial tubes. On the latter plan the tri- or quadriculate spicules, the apical rays of which are of considerable length, are arranged in two sets, one having the basal rays lying in the mesoderm of the paragastral wall and the other with the corresponding rays in the dermal mesoderm. The apical rays of each set lie in the mesoderm of the radial tubes parallel to their length, but pointing in opposite directions (fig 18 b). In the articulate division numerous spicules, small in comparison with the size of the radial tubes, form a series of rows round the tubes, their basal rays lying parallel to the paragastric surface and the apical pointing towards the ends of the radial tubes (fig 18 a).

In the *Silicispongia* sheaves of long ovoid spicules radiate from the base of the sponge if of a plate like form, or from the centre if globular, and extend to the surface. If trichites are present their arms usually extend within the mesoderm immediately below the

dermal surface (fig 19). Single spicules reach from centre to surface only in small sponges. As the sponge increases in size the spicules must either correspondingly lengthen, or fresh spicules must be added, if a continuous skeleton is to be formed. The latter is the plan followed in fact the additional spicules overlap the ends of those first formed like the fusiform cells in a woody fibre. With the formation of a fibre, often strengthened by spongin or bound together with connective tissue, there appears to be a tendency for the constituent spicules to diminish in size, and the length of each in the most markedly fibrous sponges is in significant when compared with the length of the fibre. The spicular fibre thus formed may be simple or echinated by spicules either similar to those which form its mass or different. More usually they are different, and generally styles, often spinose about their origin. The spongin which sometimes cements together the spicules of a fibre may progressively increase in quantity and the spicules diminish in number, till a horny fibre containing one or more rows of small oxeas results. In an echinated fibre the axial spicules may disappear and the echinating spicules persist. Finally all spicules may be suppressed and the horny fibre of the *Ceratosa* sponges results. The horny fibres may next acquire the habit of embedding foreign bodies in their substance, though foreign enclosures are not confined to the *Ceratosa* but occur in some *Silicispongia* as well. The included foreign bodies may increase in quantity out of all proportion to the horny fibres, and finally the skeleton may consist of them alone, all spongin matter having disappeared.

FIG 19.—Mode of arrangement of spicules in a young Stelletid sponge, *Dragmastra normani*, Soll. After Sollas.

In the *Lathustid* sponges a skeleton is produced by the articulation of desmas into a network. The rays of the desmas (figs 12 f, 13 s, 14 c) terminate in apophyses, which apply themselves to some part of adjacent desmas, either to the centrum, shaft, arms, or similar apophyses, and then, growing round them like a saddle on a horse's back, clasp them firmly without ankylosis. Thus they give rise to a rigid network, in conjunction with which fibres composed of rhabdus spicules may exist. In the *Hexactinellida* both spicular felts and fibres occur, and in one division (*Dictyonina*) a rigid network is produced, not, however, by a mere clasping of apophyses, but by a true fusion. The rays of adjacent spicules overlap and a common investment of silica grows over them.

Histology

The ectoderm usually consists of simple pavement epithelial cells (*pinnacocytes*), the margins of which can be readily rendered visible by treatment with silver nitrate, best by Harmer's method¹. The nucleus and nucleolus are usually visible in preparations made from spirit specimens, the nucleus being often readily recognizable by its characteristic bulging beyond the general surface. In some sponges (*Thecaphora*) the epithelium may be replaced locally by columnar epithelium, and the cells of both pavement and columnar epithelium may bear flagella (*Aplysilla violacea*, *Oscarella lobularis*). The endoderm presents the same characters as the ectoderm, except in the Ascons and the flagellated chambers of all other sponges, where it is formed of collared flagellated cells or *choanocytes*,—cells with a nearly spherical body in which a nucleus and nucleolus can be distinguished and one or more contractile vacuoles. The endoderm extends distally in a cylindrical neck or *collum*, which terminates in a long flagellum surrounded by a delicate protoplasmic frill or collar (fig 21 g). In *Tetractinellida*, and probably in many other sponges—certainly in some—the collars of contiguous choanocytes coalesce at their margins so as to produce a fenestrated membrane which forms a second inner lining to the flagel-

¹ S. F. Harmer, "On a Method for the Silver Staining of Marine Objects," *Marine Zoology Station zu Neapel*, 1884, p. 445.

lated chamber (fig 20, 11) The presence of this membrane enables us readily to distinguish the excurrent from the

FIG 20.—Choanocytes with coalesced collars. Figs. *b* and *g* after Schulze.

aphodal canal system the flagellated chambers usually pass gradually into the aphodal canal, but the incurrent canal

enters abruptly. This abrupt termination of the incurrent canal appears to mark the termination of the ectoderm and the commencement of the endoderm. The flagellated chambers differ greatly in size in different sponges, and evidently manifest a tendency to become smaller as the canal system increases in complexity, thus *Sycon* are always larger than *Rhagon* chambers, and euryptous than aphodal *Rhagon* chambers. In most sponges except the *Ascons* the mesoderm is largely developed, and in many it undergoes a highly complex histological differentiation. In its commonest and simplest form it consists of a clear, colourless, gelatinous matrix in which irregularly branching stellate cells or connective tissue corpuscles are embedded, these may be termed *collencytes* (fig 21 *a*) and the tissue *collenchyme*. In the higher sponges (*Geodia*, *Stelletta*) it consists of small polygonal granular cells either closely contiguous or separated by a very small quantity of structureless jelly, and in this form may be termed *sarcenchyme* (fig 20). *Collenchyme* does not originate through the transformation of sarcenchyme, as one might expect, for it precedes the latter in development. Schulze (20), who has compared collenchyme to the gelatinous tissue which forms the chief part of the umbrella of "jelly-fish," describes it as becoming granular immediately in the neighbourhood of the flagellated chambers in the bath sponge, the granules becoming more numerous in sponges in which the canal system acquires a higher differentiation, till at length the collencytes are concealed by them. According to this view, sarcenchyme would appear to originate from a densely granular collenchyme. Amoeboid wandering cells or *archaocytes* (fig 22) are scattered through the matrix of the collenchyme. They evidently serve very different purposes: some appear to act as carriers of nourishment or as scavengers of useless or irritant foreign matter, others may possibly contribute to the formation of higher tissues, some certainly becoming converted into sexual products. Their parentage and early history are unknown.

A tissue (*cystenchyme*) which in some respects resembles certain forms of vegetable parenchyme occurs in some sponges, particularly *Geodina* and other *Tetractinellida*. It consists of closely adjacent large oval cells, with thin well defined walls and fluid contents. Somewhere about the middle of the cell is the nucleus with its nucleolus, supported by protoplasm, which extends from it in fine threads to the inner side of the wall, where it spreads out in a thin investing film (fig 21 *c*). *Cystenchyme* very commonly forms a layer just below the skin of some *Geodina*, particularly of *Pachymatema*, and, as on teasing the cortex of this sponge a large number of refringent fluid globules immiscible with water are set free, it is just possible that it is sometimes a fatty tissue, and if so the contained oil must be soluble in alcohol, for alcoholic preparations show no trace of it. A tissue resembling cartilage, *chondrichyme*, occurs in *Corticium* (fig 21 *b*).

Connective-tissue cells or *desmacytes* are present in most *Desmacytes* sponges, they are usually long fusiform bodies, consisting of a clear, colourless, often minutely fibrillated sheath, surrounding a highly refringent axial fibre, which stains deeply with reagents (fig 21 *d*). In other cases the desmacyte is simply a fusiform granular cell, with a nucleus in the interior and a fibrillated appearance towards the ends. The desmacytes are gathered together, their ends overlapping, into fibrous strands or felted sheets, which in the ectosome of some sponges may acquire a considerable thickness, often constituting the greater part of the cortex. The spicules of the sponge often furnish them with a surface of attachment, especially in the *Geodina*, where each sterrator of the cortex is united to its neighbours by desmacytes, in the manner shown in fig 10.

Contractile fibre cells or *myocytes* occur in all the higher *Myocytes* sponges. They appear to be of more than one kind. Most *Myocytes* usually they are fine granular fusiform cells with long filiform terminations, and with an enclosed nucleus and nucleolus (fig 21 *e*). In the majority of sponges both excurrent and incurrent canals are constricted at intervals

by transverse diaphragms or *tela*, which contain myocytes concentrically and sometimes radiately arranged. The excessive development of myocytes in such a velum gives rise to muscular sphincters such as those which close the choanes of many corticate sponges, such as *Pachymatisma*. In this sponge, which occurs on the British shores, the function of the oscular sphincters can be readily demonstrated, since irritation of the margin of the oscule is invariably followed after a short interval by a slow closure of the sphincter.

*Æstha-
cytes*

Supposed sense-cells or *æsthiocytes* (fig 22) were first observed by Stewart and have since been described by Von Lendenfeld (12). According to the latter, they are spindle-shaped cells, 0.01 mm long by 0.002 thick, the distal end projects beyond the ectodermal epithelium in a fine hair or palpocil, the body is granular and contains a large oval nucleus, and the inner end is produced into fine threads, which extend into the collenchyme and are supposed—though this is not proved—to become continuous with large multiradiate collencytes, which Von Lendenfeld regards as multipolar ganglion cells (fig 22).

FIG 22.—Transverse section through the edge of a pore in *Dendrilla cavernosa*. Lfd cells in the middle to the right; myocytes fusiform cells on each side of them; myocytes 'g' above and below these, with processes terminating against the epithelium; gland cells fusiform cells terminating against the epithelium at 'a'; æsthiocytes at their inner ends these are continuous with ganglion cells. After Von Lendenfeld (x 500).

More recently he has described an arrangement of these cells curiously suggestive of a sense-organ. Numerous *æsthiocytes* are collected over a small area, and at their inner ends pass into a granular mass of cells with well marked nuclei, but with boundaries not so evident, these he regards as ganglion cells. From the sides of the ganglion other slender fusiform cells, which Von Lendenfeld regards as nerves, pass into the mesoderm, running tangentially beneath the skin. The inner end of the ganglion is in communication with a membrane formed of fusiform cells which Von Lendenfeld regards as muscular. If his observations and inferences are confirmed, it is obvious that we have here a complete apparatus for the conversion of external impressions into muscular movements.

plasmic
con-
tinuity

In most sponges a direct connexion can be traced by means of their branching processes between the collencytes of the mesoderm and the cells of the ectodermal and endodermal epithelium and the choanocytes of the flagellated chambers. As the collencytes are also united amongst themselves, they place the various histological constituents of the sponge in true protoplasmic continuity. Hence we may with considerable probability regard the collencytes as furnishing a means for the transmission of impulses. In other words, we may attribute to them a rudimentary nervous function. In this case the modification of some of the collencytes in communication with the ectoderm might readily follow and special *æsthiocytes* arise. Uniform collencytes perpendicular to the ectoderm, and with one end touching it are common in a variety of sponges, but it is difficult to trace the inner end into connexion with the stellate collencytes, so that precisely in

those cases in which it would be most interesting to find such a connexion absolute proof of it is wanting.

The colour of sponges usually depends on the presence of cells containing granules of pigment, though dispersed generally through the mesoderm, these cells are most richly developed in the ectosome. Pigment granules also occur in the choanocytes of some sponges, — *Oscarella lobularis* and *Aplysina aerophoba*, for instance. In the latter the pigment undergoes a remarkable change of colour when the sponge is exposed to the air, and finally fades away. In many cases sponges borrow their colours from parasitic algae (*Oscillatoria* and *Nostoc*) with which they are infested. The colours of sponge-pigments are very various. They have been examined by Krukenberg and Merejknovsky. Zoonerythin, a red pigment of the lipochrome series, is one of the most widely diffused, it is regarded as having a respiratory function. Reserve cells or *thesocytes* (fig 21 f) have been described in several sponges as well as amylin and oil-bearing cells.

Each spicule of a sponge originates in a single cell (fig 21 h-n), within which it probably remains enclosed until it has completed its full growth, the cell then probably atrophies. During its growth the spicule slowly passes from the interior to the exterior of the sponge, and is finally (in at least some sponges, *Geodia*, *Stelletta*) cast out as an effete product. The sponge is thus constantly producing and disengaging spicules, and in this way we may account for the extraordinary profusion of these structures in some modern marine deposits and in the ancient stratified rocks. Within the latter these deciduous spicules have furnished silica for the formation of flints, which have been produced by a silicious replacement of carbonate of lime (26).

The horny fibres of the *Ceratosa* are produced as a secretion of cells known as *sponginblasts*, which surround as a continuous mantle the sides of each growing fibre, and cover in a thick cap each growing point (fig 23). The

FIG 23.—Section through the horny fibre and associated tissues of a horny sponge (*Dendrilla*). A longitudinal section, s, layers of spongin, surrounded at the sides by the lateral mantle of sponginblasts and at the ends by the terminal cap. A desmochymatous sheath, a, surrounds the whole (x150). B transverse section. In the centre is the soft core, surrounded by wavy spongin layers, the outermost being surrounded by sponginblasts and these by a fibrous sheath, f, part of an incurrent canal lined by flagellated epithelium, e, part of an excurrent canal, f, part of a flagellated chamber (x150). After Von Lendenfeld.

lateral sponginblasts are elongated radially to the fibre, the terminal cells are polygonal and depressed. The latter give rise to the soft granular core and the former to the spongin-walls of the fibre. Cells similar to the lateral sponginblasts, and regarded as homologous with them, occur in a single layer just below the outer epithelium of some horny sponges (*Aplysilla* and *Dendrilla*), and under certain circumstances secrete a large quantity of slimy mucus (11).

Classification

Classification The phylum *Parazoa* or *Spongiae* consists of two main branches, as follows —

Branch A — *MEGAMASTICTOR* Branch B — *MICROMASTICTOR*

Class CALCAREA, Grant.
Order 1 — *Homocela*, Pol
Order 2 — *Heterocela*, Pol

Class I — MYXOSPONGIÆ,
Haeckel
Order 1 — *Haliscarcina*
Order 2 — *Chondrosina*

Class II — SILICISPONGIÆ

Sub-class 1 — *HEXACTINELLIDA*,
O Schmidt

Order 1 — *Lyssacina*, Zittel
Order 2 — *Dictyonina*, Zittel

Sub-class 2 — *DEMOSPONGIÆ*,
Sollas

Tribe a — *Monaxonida*

Order 1 — *Monaxona*
Order 2 — *Ceratosia*, Grant.

Tribe b — *Tetractinellida*,
Marshall.

Order 1 — *Choristida*, Sollas
Order 2 — *Lithistida*, O S

Position By the possession of both sexual elements and a complex histological structure, and in the character of their embryological development, the sponges are clearly separated from the *Protozoa*, on the other hand, the choanoflagellate character of the endoderm, which it retains in the flagellated chambers throughout the group without a single exception, as clearly marks them off from the *Metazoa*. They may therefore be regarded as a separate phylum derived from the choanoflagellate *Infusoria*, but pursuing for a certain distance a course of development parallel with that of the *Metazoa*.

Different views have been propounded by other authors. Savile Kent regards the sponges as *Protozoa* (10), Balfour suggested that they branched off from the *Metazoan* phylum at a point below the *Coelentera*, and considered them as intermediate between *Protozoa* and *Metazoa*, Schulze regards them as derived from a simple ancestral form of *Coelentera* (23), Marshall advocates the view that they are degraded forms derived from *Coelenterates* which were already in possession of tentacles and mesenteric pouches (14).

Subdivision in groups As a phylum the *Spongiae* are certainly divisible into two branches, one including the *Calcarea* and the other the remaining sponges, which Vosmaer has termed *Non Calcarea* and others *Plethospongiae*. Since, however, the choanocytes of the *Calcarea* are usually, if not universally, larger than those of other sponges, we may make use of this difference in our nomenclature, and distinguish one branch as the *Megamastictora* (μαστικτωρ, "scourger") and the other as the *Micromastictora*.

Branch A. — *MEGAMASTICTORA*

Sponges in which the choanocytes are of comparatively large size, 0.005 to 0.009 mm in diameter (Haeckel, 6)

Class CALCAREA.

Calcarea. *Megamastictora* in which the skeleton is composed of calcareous spicules

Order 1 *HOMOCELA*. — *Calcarea* in which the endoderm consists wholly of choanocytes. Examples *Leucosolenia*, Bwk., *Homoderma*, Lfd.

Order 2 *HETEROCELA*. — *Calcarea* in which the endoderm is differentiated into pinnaocytes, which line the paragastric cavity and excurrent canals, and choanocytes, which are restricted to special recesses (radial tubes or flagellated chambers). Examples *Sycon*, O S., *Grantia*, Fl., *Leuconia*, Bwk.

Branch B — *MICROMASTICTORA*

(*Non-Calcarea*, Vosmaer, *Plethospongiae*, Sollas) Sponges in which the choanocytes are comparatively small, 0.003 mm in diameter

Class I MYXOSPONGIÆ.

Myxospongiae *Micromastictora* in which a skeleton or scleres are absent

Order 1 *HALISCARCINA*. — *Myxospongiae* in which the canal system is simple, with simple or branched *Sycon* or euryplous Rhagon chambers. An ectosome sometimes and a cortex always absent. Examples *Haliscarca*, Duj., *Oscarella*, Vosm., *Bagalus*, Lfd.

Order 2 *CHONDROSINA*. — *Myxospongiae* in which the canal system is complicated, with diploidal Rhagon chambers and a well developed cortex. Example *Chondrosina*, O S.

The *Haliscarcina* are evidently survivals from an ancient and primitive type. The simplicity of the canal system is opposed to the view that they are degraded forms, we may therefore regard the absence of scleres as a persistent primary and not a secondary acquired character. They are as interesting, therefore, from one

point of view (absence of scleres) as the *Ascones* are from another (undifferentiated endoderm). With the *Chondrosina* the case is different, they differ only from *Chondrilla* and its allies by the absence of asters, these differ only from the *Tethyidae* by the absence of strongly locas, and we may very reasonably assume that in these three groups we have a series due to loss of characters, the *Chondrilla* being reduced *Tethyidae* and the *Chondrosina* reduced *Chondrilla*. Still, as Huxley has well remarked, "classification should express not assumptions but facts", and therefore till we are in possession of more direct evidence it will be well to exclude the *Chondrosina* from the *Silicispongiae*.

Class II SILICISPONGIÆ.

Micromastictora possessing a skeleton or scleres which are not calcareous.

Sub-class 1 *HEXACTINELLIDA*.

Silicispongiae characterized by seradate siliceous spicules. *Hexactinellida* Canal system usually simple, with *Sycon* chambers. *Sponge nellida* differentiated into ecto, choano, and endosome.

Order 1 *LYSSACINA*. — *Hexactinellida* in which the skeleton is formed of separate spicules, or, if united, then by a subsequent not a contemporaneous deposit of silica. Examples *Euplectella*, Owen, *Asconema*, S. Kent, *Hyalocoma*, Gray, *Rossella*, Crtr.

Order 2 *DICTYONINA*. — *Hexactinellida* in which seradate spicules are cemented together by a siliceous deposit into a continuous network *pari passu* with their formation. Examples *Favos*, Bwk., *Euclia*, Marshall, *Aphocallistes*, Gray, *Umbilicaria*, Gray, *Dactylocarya*, Stutchbury.

The *Hexactinellida* are a very sharply defined group, impressive with marked archaic features. No other *Silicispongiae* possess, so far as is known, so simple a syconate canal system. The oldest known fossil sponge is a member of the *Lyssacina* (7 and 24), viz., *Protospongia*, Salter, from the Menapian beds, Lower Cambrian, St David's Head, Wales. The group is almost world wide in distribution, chiefly affecting deep water, from 100 to 300 fathoms, but often extending into abyssal depths, occasionally, however, though rarely, it frequents shallow water (*Cystispongia supras* dredged off Yucatan in 18 fathoms).

Sub-class 2 *DEMOSPONGIÆ*.

Silicispongiae in which seradate spicules are absent

Demospougie

Tribe a *MONAXONIDA*

Demospougie in which the skeleton consists either of siliceous spicules which are not quadriradate, or of horny scleres or in eluded foreign bodies, or of one or more of these constituents in conjunction.

Order 1 *MONAXON*. — The skeleton is characterized by either uniaxial or polyaxial spicules. Examples *Amorphina*, O S. ("crumb of bread" sponge), *Sponquilla*, Lmk. ("freshwater" sponge), *Chalina*, Bwk., *Tethya*, Lmk.

Order 2 *CERATOSA*. — The skeleton consists of horny scleres which never include "proper" spicules, or of introduced foreign bodies, or of both these in conjunction. Examples *Darracella*, F. Müller, *Euspongia*, Bronn (the "bath" sponge).

Tribe b *TETRACTINELLIDA*

Demospougie possessing quadriradate or triune spicules or Lithistid scleres (desmas).

Order 1 *CHORISTIDA*. — *Tetractinellida* with quadriradate or triune spicules, which are never articulated together into a rigid network. Examples *Tetilla*, O S., *Thema*, Gray, *Geodia*, Lmk., *Deratis*, Gray.

Order 2 *LITHISTIDA*. — *Tetractinellida* with branching scleres (desmas), which may or may not be modified tetrad spicules, articulated together to form a rigid skeleton. Triune spicules may or may not be present in addition. Examples *Theonella*, Gray, *Coral lites*, O S., *Azorea*, Crtr., *Velutina*, O S.

This large sub class embraces the great majority of existing sponges. Its external boundaries are fairly well defined, its internal divisions much less so, as its various orders and families pass into each other at many points of contact. Although there does not appear to be much resemblance between a Lithistid sponge, such as *Theonella*, a Monaxonid such as *Amorphina*, and an ordinary "bath" sponge (*Euspongia*), yet between these extremes a long series of intermediate forms exists, so nicely graduated as to render their disruption into groups by no means an easy task. If the delimitation of orders is difficult, that of genera is often impossible, so that they are reduced to assemblages depending on the fact or taste of the author. Thus Polejaeff states that with a single exception "none of the genera of *Ceratosia* are separable by absolute characters". The chief spicules of *Monaxona* are uniaxial, often uniaxially panned by characteristic microscleres. Although distinguished as a group by the absence of quadriradate or triune spicules, two exceptions are known in which these occur (*Tricentron*, Flier, and *Acarinus*, Gray), these, however, present unusual characters which suggest an independent origin. The canal system of *Monaxona* has not yet been fully investigated, it appears usually to follow the

enrypylous Rhagon type, but the aphodal is not unknown. The *Ceratosa* contain all sponges with a horny skeleton, except those in which the horny fibres are cored or spined with silicious spicules secreted by the sponge ("proper" spicules), these are arbitrarily assigned to the *Monaxonida*. There is convenience in thus proceeding, for horny matter is widely disseminated throughout the *Demospongiae*, occurring even in the *Lithistida*, and it frequently serves to cement the oxeate spicules of the *Monaxonida* into a fibre, without at the same time forming a preponderant part of the skeleton. It would be wellnigh impossible to say where the line should be drawn between a fibre composed of spicules cemented by spongin and one consisting of spongin with embedded spicules, while there is comparatively no difficulty in distinguishing between fibres containing spicules and fibres devoid of them. That the distinction, however, is entirely artificial is shown by the fact that, after spicules have disappeared from the horny fibre, they may still persist in the mesoderm, thus Von Lendenfeld announces the discovery of microscleres (cymba) in an Aplysillid sponge and of strongyles in a *Cacospongia*, both horny sponges. (A form intermediate between this Aplysillid and the *Desmachoides* would appear to be *Toxochalina*, Ridley.) The *Ceratosa* frequently enclose sand, *Foraminifera*, deciduous spicules of other sponges and of compound Ascidians, and other foreign bodies within the horny fibres of their skeleton, they also sometimes attach this material, probably by a secretion of spongin, to their outer surface, and thus invest themselves in a thick protective crust. In some *Ceratosa* no other skeleton than that provided by foreign enclosures is present. The canal system is syconate or enrypylous in the simpler forms and diploidal in the higher. The *Monaxonida* make their earliest appearance in the Silurian rocks (*Climacospongia*, Hinde), and are now found in all seas at all depths. The only sponges inhabiting fresh water belong to this group. The *Tetractulidæ* adhere to the *Monaxonida* at more than one point, and one of these groups has probably been a fruitful parent to the other, but which is offspring and which parent is still a subject for discussion. The *Choristida* in its simplest forms presents a curypylous Rhagon system, in the higher an aphodal system. It is in this group that the most highly complex cortex is met with, in the *Geodimidae*, for instance, it consists usually of at least five distinct layers. Thus, proceeding outwards, next to the choanosome is a layer of thickly felted desmachyme, passing into collenchyme on its inner face, then follows a thick stratum of sternasters united together by desmacytes, this is succeeded by a layer of cystenchyme or other tissue of variable thickness, external to this is a single layer of small granular cells and associated dermal asters, and finally, the surface is invested by a layer of pavement epithelium. The *Lithistida*, like the *Ceratosa*, are possibly of polyphyletic origin, in one group (*Tetractadina*) the articulated scleres are evidently modified calthrops spicules (see fig. 14 c), and associated with them are free trirames, which support the dermis and resemble precisely the trirames of the *Choristida*. In another group (*Rhabdocyprida*) the scleres are moulded on a Monaxonid base (see fig. 13 g s), but, associated with them, trirames sometimes occur similar to those of the *Tetractadina*. Both these groups are in all probability derived from the *Choristida*, and a distinct passage can be traced from the *Tetractadose* to the *Rhabdocyprid* group. In the *Rhabdocyprida* we find forms without trirames, these may possibly be degenerate forms. The third group of *Lithistids* is derived from the *Rhabdocyprida*, the *Anomocladinae* desma being derivable from the *Rhabdocyprid* by a shortening of the main axis into a centrum. The thick centrum, from which the arms, variable in number, originate, is hollowed out by a cavity, which appears during life to have been occupied by a large nucleus, like that of a scleroblast, and it is quite conceivable that the scleroblast, which in the *Tetractadine* *Lithistids* lies in an angle between the arms, may have become enclosed in an overgrowth of silica, from which additional arms were produced. The constancy with which spicules in other sponges maintain their independence is very striking. When once a persistent character like this is disturbed, excessive variability may be predicted, as in the *Anomocladine* scleres.

The classification of the sponges into families is shown in the following scheme

Class CALCAREA

Order 1 HOMOCOLA, Pol

Family 1 ASCONIDÆ, Hk. — *Homocela* which are simple or composite, but never develop radial tubes. Examples *Ascella*, Hk. (fig. 1), *Leucosolenia*, Bwk.

Family 2 HOMODERMIDÆ, Lfd. — *Homocela* with radial tubes. Example *Homoderma*, Lfd. (figs. 3, 4)

Order 2 HETEROCOLA, Pol

Tribe a. SYCONARIA¹

The flagellated chambers are either radial tubes or cylindrical sacs.

Family 1 SYCONIDÆ. — The radial tubes open directly into the paragastric cavity

Sub-family a SYCONINA. — The radial tubes are free for their whole length, or at least distally. Examples *Syccella*, Hk., *Sycon*, O S. Sub-family b UTEINA, Lfd. — The radial tubes are simple and entirely united. The ectosome is differentiated from the choanosome and sometimes develops into a cortex. Examples *Grantissa*, Lfd., *Ute*, O S (fig. 5), *Syccellula*, Hk., *Amphoriscus*, Pol.

Sub-family c GRANTINA, Lfd. — The radial tubes are branched. The incurrent canal system is consequently complicated. An ectosome is present. Examples *Grantia*, Fl., *Heteropegma*, Pol (fig. 4), *Anamastilla*, Pol.

Family 2 SYLLEPTIDÆ, Lfd. — The choanosome is folded. The flagellated chambers (which are partly rhagose in *Vosmaeria*) communicate with the paragastric cavity by excurrent canals. Examples *Poleyna*, Lfd (fig. 6), *Vosmaeria*, Lfd.

Family 3 TETRACHONELLIDÆ, Carter. — Composite *Sylleptidæ* with the oscules and pores occurring on different parts of the surface. Example *Tetrachonella*, Crtr.

Tribe b. LITHONARIA

The canal system belongs to the enrypylous Rhagon type.

Family 1 LITHONIDÆ, Hk. — The outer surface is not differentiated into osculiferous and poriferous areas. Examples *Leucella*, Hk., *Leucotis*, Hk.

Family 2 LITHARDIDÆ, Pol. — Composite *Leuconaria*, with the outer surface differentiated into special osculiferous and poriferous areas. Example *Eilhardia*, Pol.

The arrangement adopted above is founded on Von Lendenfeld's revision (11) of the classification propounded by Polyschiff (16), who in a masterly survey has thrown an unexpected light on the structure and inter relationships of a group which Haeckel has rendered famous. It should not be overlooked that Vosmaer (32) had previously explained the structure of the *Leucones*. However erroneous in detail, Haeckel's views are confirmed in their broad outlines, and it was with true insight that he pronounced the *Calcarea* to offer one of the most luminous expositions of the evolutionary theory. In this single group the development in general of the canal system of the sponges is revealed from its starting-point in the simple *Ascon* to its almost completed stage in the *Leucon*, with a completeness that leaves little further to be hoped for, unless it be the requisite physiological explanation.

Class MIXOSPONGIÆ

Order 1 HALISARCINA

Family 1 HALISARCIDÆ, Lfd. — The flagellated chambers are syconate. Examples *Halisarca*, Duj (with branched chambers), *Bagalus*, Lfd (with simple chambers).

Family 2 OSCARELLIDÆ, Lfd. — The flagellated chambers are curypylous and rhagose. Example *Oscarella*, Vosm.

Order 2 CHONDROSINA

Family 1 CHONDROSIDÆ. — With the characters of the order. Example *Chondrosia*, O S.

Class SILICISPONGIÆ

Sub-class I HEXACTINELLIDA

Order 1 LYESACINA

Family 1 EUPLECTELLIDÆ. — The spicules of the dermal membrane are "daggers" (fig. 15 a). Examples *Euplectella*, Owen, *Holascus*, E Sch., *Habrodactylum*, W T.

Family 2 ASCONEMATIDÆ. — The dermal spicules are "pinnuli" (fig. 15 b, c). Examples *Asconema*, S Kent, *Sympagella*, O S., *Caulophæus*, Schulze.

Family 3 HYALONEMATIDÆ. — The dermal spicules are pinnuli and awnlike (fig. 15 d). Example *Hyalonema*, Gray.

Family 4 ROSSELLIDÆ. — The dermal spicules are goniphi, stauri (fig. 15 f), and oxeas. Examples *Rossella*, Crtr., *Crateromorpha*, Gray, *Aulochona*, E Sch.

Family 5 REOPHTACULIDÆ, Hinde. — The distal ray of the dermal spicules is expanded horizontally into a polygonal plate. Example **Receptaculites*, Defr.

Order 2 DIOTYONINA

Sub-order 1 UNCIATARIA

Uncinate spicules are present.

Tribe a. CLAVULARIA

Clavules (fig. 16 c) are present.

Family 1 FARREIDÆ. — Characters those of the tribe. Example *Farrea*, Bwk.

Tribe b. SCOPULARIA

The dermal spicules are scopularine (fig. 16 b).

Family 1 EURYTIDÆ. — Branched anastomosing tubes, or goblet-shaped, with lateral outlets. Examples *Eurete*, Marshall, *Periphragella*, Marshall, *Lefroyella*, Schulze.

Family 2 MELLITTOIDÆ. — Tubular or goblet shaped, with honeycomb like walls. Example *Aphrocallistes*, Gray.

¹ An * indicates that the group is only known in the fossil state, a † that it is both recent and fossil.

Family 3 **†CHONELASMATIDÆ**—Flat or beaker shaped, straight funnel-shaped canals perforating the wall perpendicularly and opening laterally on each side. Example *Chonelasma*, Schulze

Family 4 **†VOLUVIINIDÆ**—Tubular, goblet shaped, or massive, crooked canals more or less irregular in their course. Examples *Voluvina*, Schulze, *Fieldingia*, S Kent

Family 5 **SCIPHOIUMINIDÆ**—Arborescent body, perforated at the ends and sides by round narrow radiating canals. Example *Sclerothamnus*, Marshall

Sub order 2. **INERAMIA**

Dutyonina without mucinati, clavate, or scopularia

Family 1 **†MYLIUSIDÆ**—Depressed cup shaped, a complex folding of the wall produces lateral occurrent tubes. Example *Myliusia*, Gray

Family 2 **†DACTYLOCALICIDÆ**—Goblet-shaped or pteriform, with a thick wall consisting of numerous parallel anastomosing tubes, of uniform breadth, which terminate at the same level within and without. Examples *Dactylocalya*, Gray, *Scleroplegma*, O S, *Margaritella*, O S

Family 3 **†EURYPLEGMATIDÆ**—Goblet shaped or resembling ear shaped saucers, the wall deeply folded longitudinally so as to produce a number of dichotomously branched canals or covered in grooves. Example *Euryplegma*, Schulze

Family 4 **†AULOCYSTIDÆ**—Of massive rounded form, with an axial cavity, wall consisting of a system of obscurely radiating anastomosing tubes and intervening inter canals, both inter canals and the external terminations of the tubes are covered by a thin membrane, which is perforated by slit like openings over the lumina of the tubes, and thus assumes a sieve like character. Examples *Aulocystis*, Schulze, *Cystispongia*, Roomer

This arrangement of the *Hexactinellida* is taken from the latest work on the subject, Schulze's *Preliminary Report on the "Challenger" Hexactinellida*. The reference of fossil forms to the families here instituted is rendered difficult by the disappearance of the requisite "guiding" spicules in the process of mineralization. A revision of the fossil families to bring them into harmony with the recent has certainly been rendered necessary, but this is too large a task to undertake in this place

Sub-class II **DEMOSPONGIÆ**

Tribe **α** **MONAXONIDA**

Order 1 **MONAXONA**

Family 1 **TETHYIDÆ**—Skeleton consisting of radiately arranged strongylones (except in the genus *Chondrilla*, which is without megascleres) and large sphaerasters. The ectosome is a thick fibrous cortex. Example *Tethya*, Lmk., *Chondrilla*, O S

Family 2 **POLYMASTIDÆ**—Skeleton consisting of styles radiately arranged and cortical tylostyles. The oscules in many cases open at the ends of long papilla. Examples *Polymastia*, Bwk., *Theca phora*, O S, *Trichostemma*, Sars

Family 3 **SUBERITIDÆ**—Skeleton consisting of strongylate or tylostate styles, arranged to form a felt. The flesh spicules when present are usually microrhabds or spirasters. Examples *Suberites*, Nardo, *Chona*, Grant, *Poterion*, Schlegel

Family 4 **DESMACIDONIDÆ**—The flesh spicules are eymbas. Examples *Esperella*, Vosm., *Desmacidon*, Bwk., *Cladorhiza*, Sars

Family 5 **†HALIONODRIDÆ**—The flesh spicules when present are not or eymbas. Examples *Halichondria*, Fl., *Romeria*, O S, *Chalina*, Bwk., **Pharetrasporgia*, Soll

Family 6 **EOTYONIDÆ**—The skeleton consists of fibres ciliated by projecting spicules. Examples *Plocama*, O S, *Edyon*, Gray, *Clathria*, O S

Family 7 **†SPONGILLIDÆ**—*Halichondridæ* which are reproduced both sexually and by statoblasts. Habitat freshwater. Examples *Spongilla*, Lmk., *Ephydatia*, Lmk., *Farmula*, Crtr., *Potamohippocampus*, Marshall¹

The foregoing classification is purely provisional, the group requires a complete revision

Order 2 **CERATOSA**

Family 1 **DARWINELLIDÆ**—Canal system of the eurypylous Rhagon type. Flagellated chambers, pouch shaped, large, the surrounding collenchyme not granular. Horny fibres with a thick core. Examples *Darwinella*, Fritz Müller, *Aphysilla*, F.E.S., *Janthella*, Gray

Family 2 **SPONGELIDÆ**—Canal system as in the *Darwinellidæ*, but the flagellated chambers more or less spherical. Horny fibres with a thin core, and usually containing foreign enclosures. Examples *Pelnea*, Vosm., *Spongelia*, Nardo, *Psammoclema*, Marshall, *Psammoclema*, Marshall

Family 3 **SPONGIDÆ**—Canal system aphodal. Chambers small and spherical, surrounding collenchyme granular. Fibres with a thin core. Examples *Euspongia*, Bronn, *Coscinoderma*, Crtr., *Phyllospongia*, Ehlers

¹ Freshwater sponges without statoblasts are excluded from this family, and left for distribution amongst allied marine genera

Family 4 **ALLISIIDÆ**—Canal system diploidal, collenchyme surrounding the flagellated chambers densely granular. Fibres with a thick core. Examples *Luffaria*, Duch and Mich., *Verongia*, Bwk., *Aplysina*, Nardo

The species of sponge in common use are three,—*Euspongia officinalis* (Linn.), the imo Turkey or Levant sponge, *E. zimocca* (O S), the hard Zimocca sponge, and *Hypospongia equina* (O S), the horse sponge or common bath sponge. The genus *Euspongia* is distinguished by the regular development of the skeletal network throughout the body, its narrow mesicles, scarcely or not at all visible to the naked eye, and the regular radiate arrangement of its chief fibres. *Hypospongia* is distinguished by the thinness of its fibres and the labyrinthine character of the ectosome beneath the skin. As a consequence its chief fibres have no regular radiate arrangement. The species of *Euspongia* are distinguished as follows. In *E. officinalis* the chief fibres are of different thicknesses, irregularly swollen at intervals, without exception cored by sand grains, in *E. zimocca* they are thinner, more regular, and almost free from sand. In *E. officinalis*, again, the uniting fibres are soft, thin, and elastic, whilst in *E. zimocca* they are denser and thicker, to which difference the latter sponge owes its characteristic hardness. Finally, the skeleton of *E. officinalis* is of a lighter colour than that of *E. zimocca*. The common bath sponge (*Hypospongia equina*) has almost always a thick cork like form, but its specific characters are not yet further defined

Tribe **β** **TFTRACTINIFILIDA**

Order 1 **CHORISTIDA**

Sub-order 1 **SIGMATOPHOR I**

The microsclere is a sigmaspire.

Family 1 **TETRIIDÆ**—The characteristic megasclere is a protriene. Canal system in the lower forms eurypylous, in the higher aphodal. The ectosome in the simpler forms is a dermal membrane, in the higher a highly differentiated cortex. Examples *Tetilla*, O S, *Craniella*, O S (fig 21 h, i)

Family 2 **SAMIDÆ**—The characteristic megasclere is an amphitriene. Example *Samus*, Gray

Sub order 2 **ASTROPHOR I**

The microsclere is an aster

Group 1 **SPIRASTROSA**—A spiraster is usually present

Family 1 **THYRIDÆ**, Carter—The flesh spicule is a spiraster. Canal system eurypylous. Ectosome not differentiated to form a cortex. Examples *Thenea*, Gray (fig 21 a, f), *Pacillaster* (*Normania*), Bwk.

Family 2 **†PACHIASTHILLIDÆ**—Canal system eurypylous in the lower, aphodal in the higher forms. Examples *Plakotis*, F.E.S., *Dreclius*, Gray

Group 2 **EUASTROSA**—Spirasters are absent

Family 1 **†STHICTETIDÆ**—Canal system aphodal, but approaching the eurypylous in the lower forms. The cortex chiefly consists of collenchyme in the lower forms, in the higher it is highly differentiated. Example *Stelletta*, O S. (fig 11), *Ancorina*, O S, *Myriastrea*, Soll

Family 2 **TETHYIDÆ**—Although this family has been placed in the *Monaxonida*, this seems to be its more natural position

Group 3 **STERRASTROSA**—A sternaster is present, usually in addition to a simple aster

Family 1 **†GEODINIDÆ**—The megascleres are partly trienes. Canal system always aphodal. Cortex highly differentiated. Examples *Geodia*, Lmk. (fig 21 n), *Pachymatisma*, Bwk. (fig 21 c), *Cydonium*, Müller (fig 10), *Erylus*, Gray

Family 2 **PLAOSPONGIDÆ**—The megasclere is a tylostyle. Trienes are absent. Example *Placospongia*, Gray

Sub-order 3 **MICROSCLEROPHOR I**

Microscleres only are present

Family 1 **PLAKINIDÆ**, Schulze—Canal system very simple, belonging to eurypylous Rhagon type. Characteristic spicules caudelabra. Examples *Plakina*, F.E.S. (fig 26)

Family 2 **CORTICIDÆ**—Canal system aphodal or diploidal. Mesoderm a collenchyme crowded with oval granular cells, the spicules either caudelabra, amphitrienes, or trienes irregularly dispersed in it. Example *Corticium*, O S. (figs 9, 21 b)

Family 3 **THROMBIDÆ**—Canal system diploidal. Spicules trielio trienes. Example *Thrombus*, Soll

The *Pachastrellidæ* or the *Corticidæ* are probably the families from which the *Tetractelidæ* *Lathistidæ* have been derived. In the *Tetillidæ* the characteristic microsclere may occasionally fail, but there is no or any difficulty in identifying the sponge in this case, as the trienes are of a very characteristic form the arms of the protriene are slender, simple, and directed very much forwards, making a very large angle with the shaft. Microscleres, having the form of little globules, are sometimes present with the sigmaspires.

Order 2 **LITHISTIDA**, O S

Sub-order 1 **†TETRACLEDINA**, Zittel

The desmas are modified calthrops spicules.

Family 1. *TETRACLADIDÆ*.—With the characters of the sub order. Examples *Theonella*, Gray (fig 21 k), *Discodermia*, Bocage, *Siphonia*, Parkinson.

Sub-order 2. *RHABDOCREPIDA*

The desmas are of various forms, produced by the growth of silica over a uniaxial spicule

Family 1. *MEGAMORINIDÆ*.—The desmas are comparatively large Trienes, usually dichotrienes, help to support the ecto some Microscleres usually spirasters. Examples *Corallistes*, O S, *Hyalotragos*, Zittel, *Lyndium*, O S, *Dorydermia*, Zittel

Family 2. *MICROMORINIDÆ*.—The desmas are comparatively small Trienes and microscleres are both absent. Examples *Azoreca*, Crtr, *Ferruchina*, Zittel

Sub order 3. *ANOMOCLADINA*

Desmas with a massive nucleated centrum, from which a variable number of arms (28) extend radiately (see fig 12 f). Examples *Vetulina*, O S, *Asylospongia*, Roemer

Reproduction and Embryology

Fresh individuals arise by asexual gemmation, both external and internal, by fission, and by true sexual reproduction.

sexual
multipli-
cation

Fission is probably one of the processes by which compound sponges are produced from simple individuals. Artificial fission has been practised with success in the cultivation of commercial sponges for the market. External gemmation has been observed in *Thenea*, *Tethya*, *Polymastia*, and *Oscarella*. A mass of indifferent sponge-cells accumulates at some point beneath the skin, bulges out, drops off, and gives rise to a new individual. Internal gemmation, which results in the formation of a statoblast, is only known to occur in the freshwater *Spongillidae*. The statoblasts consist of a mass of yolk-bearing mesoderm cells, invested by a capsule, which in *Ephydatia fluviatilis* is composed of an inner cuticle of spongin separated from a similar outer layer by an intermediate zone of amphidisks and interspersed protoplasmic cells. On one side of the capsule is a hilum which leads into the interior.

Their development has recently been studied by Gotte, with results that confirm the conclusions of Carter (3) and Laeberkuhn (13). The process commences with an accumulation of amoeboid cells within the mesoderm to form a globular cluster, yolk granules develop within them, especially in those that lie nearer the centre. The external cells give rise to the investing capsule, some resemble spongioblasts and secrete the inner and outer horny cuticle, others give rise to the amphidisks and interspersed cells of the middle layer. Under favourable conditions the interior cells creep out through the pore of the capsule, and form a spreading heap, which by subsequent differentiation gives rise to a young *Spongilla*. Since the freshwater sponges can only be regarded as modified descendants of ancient marine species (probably of the family *Halichondridæ*), we may consider the internal gemmules, like the similar statoblasts of the freshwater *Polysoa*, as special adaptations to a changed mode of life. They appear primarily to serve a protective purpose, ensuring the persistence of the race, since they only appear in extreme climates on the approach of drought, and in cold ones on the approach of winter. As a secondary function they serve for the dispersal of the species, some are light enough to float down a stream, but not too far, so that there is no danger of their being carried to sea, others, which are characterized by large air chambers, are possibly distributed by the wind.

Sexual
repro-
duction.

Both sexual elements may be formed in the same individual, e.g., *Oscarella lobularis*, *Grantia raphanus*, and many others, but even in hermaphrodites one or other element usually occurs to excess in different individuals, so that some are predominantly male and others predominantly female. Polejaeff found only one such male form to 100 female forms in *Grantia raphanus*. In other sponges—*Reniera fertus*, *Euspongia officinalis*—the sexes are distinct. The ova develop from archæocytes or wandering amoeboid cells, which increase in size and acquire a store of reserve nourishment in the form of yolk

granules, at first they exhibit lively amoeboid movements, but later pass into a resting stage. The cavity of the mesoderm within which they are situated becomes lined

FIG 24.—Spermatozoa. a-h, Development of spermatozoa in *Sycandra raphanus*, highly magnified, h, mature spermatozoa. After Polejaeff ($\times 700$). j, A sperm ball in *O. rardella lobularis* ($\times 500$), l, an isolated mature spermatozoan. After Schulze ($\times 800$).

by a layer of epithelium, which may not appear, however, till a late stage of segmentation. In *Euspongia officinalis* the ova occur congregated in groups within the mesoderm, thus presenting an early form of ovary. The spermatozoa, which also develop from wandering amoeboid cells, are minute bodies with an oval or pear-shaped head and a long vibratile tail (fig 24 l). Each amoeboid cell produces a large number of spermatozoa, which occur in spherical clusters or sperm balls. The heads of the spermatozoa, as in the *Meta-ova*, are produced from the nucleus of the mother-cell, the tails from the surrounding protoplasm.

The development in detail is upon two plans. In *Grantia*

FIG 25.—Development of a calcareous sponge (*Sycandra raphanus*). a ovum b c ovum segmented, b, as seen from above c lateral view, d blastosphere e, amphiblastula f, commencement of the invagination of the flagellated cells of the amphiblastula g gastrula above. raphanus (15) the nucleus of the mother cell divides into two further change, but with a small quantity of peripheral protoplasm forms a "cover cell" to the other or primitive sperm nucleus and its associated protoplasm. The sperm nucleus repeatedly divides, with-

out involving the surrounding protoplasm (fig 21 e f). The resulting nuclei at length cease to exhibit a nucleolus, and become directly transformed into the heads of spermatozoa, the tails are appropriated by each head from the common protoplasmic residue. The mother cell in this case undergoes no increase in volume as development proceeds, and it is not enclosed within an "endothelium" layer. In the second and apparently more usual case (20) no "cover cell" is formed, but the mother cell divides and subdivides, protoplasm as well as nuclei, till a vast number of minute cells results, the nucleus of each becomes the head of a spermatozoon and the protoplasm its tail. In this case the sperm ball does increase in bulk, it grows as it develops, and the cavity containing it becomes lined by epithelium, or so called "endothelium" (fig 21 f). No doubt (25) the development of the epithelium stands in direct physiological connection with the growth of the sperm ball.

Embryology

Obscure as are the details of this subject, sufficient is known to enable us to make out two chief types of development. One, common amongst the calcareous sponges, and possibly occurring in a single genus (*Gumma*) of the *Micromastictora*, is characterized by what is known as the "amphiblastula" stage, the other, widely spread amongst the *Micromastictora* (*Reniera*, *Desmardion*, *Euspongia*, *Spongella*, *Aplysilla*, *Oscarella*), is characterized by a "planula" stage.

The first has been most thoroughly investigated in *Grantia raphanus* by Schulze (20). The ovum by repeated segmentation gives rise to a hollow vesicle, the wall of which is formed by a single layer of cells—blastosphere (fig 25 d). Eight cells at one pole of the blastosphere now become differentiated from the rest, they remain rounded in form, comparatively large, and become filled with granules (stored nutriment), while the others, rapidly multiplying by division, become small, clear, columnar, and flagellated. By further change the embryo becomes egg shaped, the granular cells, now increased in number to thirty two, form the broader end, and the numerous small flagellated cells the smaller end. Of the granular cells sixteen are arranged in an equatorial girdle adjoining the flagellate cells. A blastosphere thus differentiated into two halves composed of different cells is known as an *amphiblastula*. The amphiblastula (fig 25 e) now perforates the maternal tissue, and is borne along an excurrent canal to the oscule, where it is discharged to the exterior and swims about in a whirling lively dance. It then assumes a more spherical form, a change premonitory of the next most remarkable phase of its career. In this the flagellated layer becomes flattened, depressed, and finally invaginated within the hemisphere of granular cells, to the inner face of which it applies itself, thus entirely obliterating the cleavage cavity, but by the same process originating another (the invagination cavity) at its expense (fig 25 f). The two layered sac thus produced is a *paragastrula*, its outer layer, known as the *emblast*, gives rise to the ectoderm, the inner layer or hypoblast to the endoderm. The paragastrula next becomes somewhat bell-shaped, and the mouth of the paragastric cavity is diminished in size by an ingrowth of the granular cells around its margin. The larva now settles mouth downwards on some fixed object, and exchanges a free for a fixed and stationary existence (fig 25 g). The granular cells completely obliterate the original mouth, and grow along their outer edge over the surface of attachment in irregular pseudopodial processes, which secure the young sponge firmly to its seat (fig 25 h). The granular cells now become almost transparent, owing to the exhaustion of the yolk granules, and allow the hypoblast within to be readily seen, a layer of jelly like material, the rudimentary mesoderm, is also to be discerned between the two layers. The spicules then become visible, slender ovals appear first, and afterwards tri and quadri radiate spicules. The larva now elongates into a somewhat cylindrical form, the distal end flattens, and an oscule opens in its midst. Pores open in the walls, the endodermal cells, which had temporarily lost their flagella, reacquire them, at the same time extending the character istic collar. In this stage (fig 25 h, f) the young sponge corresponds to a true Ascon, no trace of radial tubes being visible, but as they characterize the parent sponge they must arise later, and thus we have clear evidence through ontogeny of the development of a Sycon sponge from an Ascon.

The three most striking features in the history of this larva are, first, the amphiblastula stage, next the invagination of the flagellate cells within the granular, instead of invagination in the reverse order, and third the attachment of the larva by the oral instead of the aboral surface. Should Schulze be correct in deriving the sponges from the *Calcitrona* it is probable that the reversal of the

Calcitrona history as exemplified in the last two events will furnish an explanation of the remarkable divergencies which distinguish the two phyla. The history of the second or planula type has been thoroughly worked out by Schulze (20) in a little interesting *Tetractinellid* sponge (*Plakina monolopha*, Schulze). The ovum by regular segmentation produces a blastosphere, the blastomeres of which

FIG. 26.—Development of a Demosponge (*Plakina monolopha*). a, planula (the central part should be shaded). b, Section through side of planula, c, Section across the foregoing. d, Young sponge (Rhagon). e, Part of a section through fully grown sponge, the attached basal layer is the hypoblast, the spongonere is solid so as to produce incurrent and excurrent canals. The canal system is (very pylons, or, ommatidia segmented ommatidia between two of them), i, blastosphere. After Schulze.

increase in number by further subdivision till they become converted into hyaline cylindrical flagellated cells (fig 26 f). Thus a blastosphere is produced consisting wholly of similar flagellated cells. It becomes egg shaped, and, hitherto colourless, assumes a rose red tint, which is deepest over the smaller end. The larva (now a planula, fig 26 a, b) by the filling in of the central cavity escapes from the parent and swims about broad end foremost. In this stage thin sections show that the cleavage cavity is obliterated, its place being occupied by a mass of granular gelatinous material containing nuclei (fig 26 b). In from one to three days after hatching the larva becomes attached. It then spreads out into a convex mass, and a cavity is produced within it by the splitting of the central jelly (fig 26 c, d, compare *Lucifer* and others amongst the *Calcitronates*). This cavity becomes lined by short cylindrical cells (endoderm), while the flagellated cells of the exterior lose their flagella and become converted into pinnacocytes (ectoderm). The gelatinous material left between the two layers now formed acquires the characters of true collagenous and thus becomes the mesoderm. The endoderm then sends off into the mesoderm, as buds, rounded chambers, which communicate with the paragastric cavity by a wide mouth and with the exterior by small pores (fig 26 e). An oscule is formed later, and the sponge enters upon the Rhagon phase. Subsequent foldings of the sponge wall give rise to a very simple canal system (fig 26 f). In addition to these two well ascertained modes of development others have been described which at present appear aberrant. In *Oscarella lobularis*, O.S. (27), a curious series of early developmental changes results in the formation of an irregular paragastrula, the walls of which become folded (while still within the parent sponge) in a complex fashion, so as to produce a form in which the incurrent and excurrent canals appear to be already sketched out before the flagellated chambers are differentiated off. In *Spongilla* Gotte describes the ectoderm as becoming entirely lost on the attachment of the larva, so that the future sponge proceeds from the endoderm alone. As *Spongilla*, however,

is a freshwater form, anomalies in its development (which remind us of those in the development of the freshwater *Hydra*) might almost be expected.

Homoplasia

Probably in no other single group is the doctrine of homoplasia enunciated by Lankester more tellingly illustrated than in the sponges. The independent development of similar types of canal system in different groups, sometimes within the limits of a single family, is a remarkable fact. In the following table the sign \times shows independent evolution of similar types of canal system in different groups—

	Ascon.	Sycon.	Rhagon		
			Eurypylous	Aphodal.	Diploclal
Class <i>Calcarea</i>	\checkmark	\times	\checkmark		
Order <i>Halisarcina</i>		\times	\times		
Order <i>Monaxona</i>			\times	\times	
Order <i>Ceratosa</i>		\times	\times	\times	\times
Sub-order <i>Microsclerophora</i>			\times	\times	\times
Order <i>Choristida</i>			\times	\times	
Family <i>Tetillidae</i>			\times	\times	

In the gross anatomy of the canal system similar homoplasia obtains, thus, to cite one case amongst many, a peculiar type of canal system characteristic of *Siphonia* (Lithistid) occurs also in *Emploca* (Hexactinellid), *Schmidtia* (Monaxonid), and other apparently unrelated genera. The development of a cortex has likewise taken place independently, but on parallel lines, in the *Syconidae*, *Leuconidae*, *Monaxona*, *Tetillidae*, and *Stellettidae*. Calcareous and silicious spicules have evidently an independent history, and yet all the chief forms of the former are repeated in the latter. Quite as remarkable is the similarity of the independently evolved horny spicules of *Darwinella aurea* to the quadri- and sex-radiate silicious spicules. We have now sufficient knowledge of the morphology and evolution of the sponge to furnish the physicist with data for an explanation of the skeleton, at least in its main outlines. The obvious conclusion from this is that variation does not depend upon accident, but on the operation of physical laws as mechanical in their action here as in the mineral world. Another important consequence follows if homoplasia—the independent evolution of similar structures—is of such certain and quite common occurrence in the case of the sponges, it is also to be looked for in other groups, and polyphyletic origin, so far from being improbable, is as likely an occurrence as monophyletic origin.

Physiology and Etymology

Physiology

Under the head of "physiology" we have almost a blank. At present we do not even know what cells of the sponge are primarily concerned in the ingestion of food. If a living sponge, such as *Spongilla*, be fed with carmine for a few minutes, then immersed in dilute osmic acid, and examined in thin sections, its flagellated chambers are found to be all marked out as red circular patches, and a closer investigation shows that the choanocytes, and they alone, have ingested the carmine. In this way we confirm the earlier observations of Carter made by teasing carmine-fed sponges. This might be thought to decide the question, but, though it effectually disposes of Polejaeff's argument that the choanocytes do not ingest nutriment because mechanical disadvantages (conceived *a priori*) make it impossible, it has not proved a final solution. Von Lendenfeld, by feeding sponges such as *Aplysilla* with carmine for a longer interval—a quarter of an hour—finds that amoeboid cells crowd about the sides and particularly the floor of the subdermal cavities, and are soon loaded with carmine granules, after a time they wander away to the flagellated chambers and there cast out into the excurrent canals the carmine they have absorbed, apparently

in an altered state. On the other hand, the choanocytes, though they at first absorb the carmine, soon thrust it out, apparently in an unaltered state. Hence Von Lendenfeld concludes that it is the epithelium of the subdermal cavities which is charged with the function of ingestion, and that the amoeboid cells subsequently digest and distribute it, and finally cast out the worthless residues. There may be much truth in this view, but it requires to be supported by further evidence. (1) Sufficient proof is not adduced to show that the carmine granules expelled from the amoeboid cells are really more decomposed than those rejected by the choanocytes. (2) There is at present no proof that carmine is a food, or that if it is sponges will readily feed upon it. In either case one would expect the amoeboid cells to play the part which they perform in other organisms and to remove as soon as possible useless or irritant matter from the surface which it encumbers, at the same time the choanocytes, not having found the food to their liking, would naturally eject it. (3) If the choanocytes do not ingest food, how does the Ascon feed, since in this sponge all the pinacocytes are external? It is, however, a very noticeable fact that, as the organization of a sponge increases in complexity, the choanocytal layers become reduced in volume relative to the whole bulk of the individual, and it is quite possible that as histological differentiation proceeds it may be accompanied by physiological differentiation which relieves the choanocytes to some extent of the ingestive part of their labours.

The origin of the sponges is to be sought for among the choanoflagellate *Infusoria*, and Savile Kent has described a colonial form of this group which is suggestively similar to a sponge. Its differences, however, are as marked as its resemblances, and have been sufficiently pointed out by Schulze (23). Kent has called this form *Protospongia*, a name already made use of, and fortunately, as the organism is not in any sense a true sponge, the present writer proposes, therefore, to call it *Savillia*, in honour of its discoverer. It consists of choanoflagellate *Infusoria* (see *Protozoa*, vol. xix. p. 858, fig. XXI, 15), half projecting from and half embedded in a structureless jelly or blastema, within which other cells of an amoeboid character and reproductive function are immersed. Professor Haddon arrives at the generalization that conjugation amongst the *Protozoa* always takes place between individuals of the same order: flagellate cells conjugate with flagellate, amoeboid with amoeboid, but never with flagellate, while in true sexual reproduction the conjugation occurs between two individual cells in different stages of their life cycle: a flagellate cell conjugates with a resting amoeboid cell. Now *Savillia* would appear to be extremely near such a true sexual process, since the simultaneous coexistence of cells in two different stages of life and within easy reach of each other—a necessary preliminary, one would think, to the union—has already been brought about. That coalescence between two different histological elements should result in products similarly histologically differentiated (compare amphiblastula stage of *Calcarea*) has in it a certain fitness, which, however, has still to be explained. The mode by which an organism like *Savillia* might become transformed into an Ascon cannot be suggestively outlined with any satisfactory results till our knowledge of the embryology of sponges is more advanced. The minute characters of the flagellate cells of the amphiblastula and other sponge larvæ are still a subject for research. They often possess a neck or collum, but the existence of a frill or collar is disputed. Kent asserts that it is present in several embryos which he figures, and Barrois makes the same assertion in respect to the larva of *Oscarella*, and illustrates his description with a figure. On the other hand, Schulze and Marshall both

deny its existence, and the former attributes Kent's observations to error. One constant character they do possess they are provided with flagella at some stage of their existence, but never with cilia. Ciliated cells, indeed, are unknown amongst the sponges, and, when pinnaecytes exceptionally acquire vibratile filaments, as in *Oscarella* and other sponges, these are invariably flagella, never cilia. An Ascon stage having been reached at some point in the history of the sponges, the Sycon tubes and Rhagon chambers would arise from it by the active proliferation of choanocytes about regularly distributed centres, possibly as a result of generous feeding. Vosmaer recognized as the physiological cause of Sycon an extension of the choanocyst layer. Polejaeff, relying on Von Lendenfeld's experiments, which seem to prove that it is the pinnaecytes and not the choanocytes which are concerned in the ingestion of nutriment, argues that, as in Sycon the pinnaecyst layer is increased relatively to the choanocyst, we have in this a true explanation of the transition. The existence of *Homoderma*, Lfd, however, shows that in the first stage there was not a replacement of choanocytes by pinnaecytes, but that this was a secondary change, following the development of radial tubes, and therefore cannot be relied upon to explain them. The radial tubes having been formed by a proliferation of choanocyst cells, the reduction of those lining the paragastric cavity to pinnaecytes would follow in consequence of the poisonous character of the water delivered from the radial tubes to the central cavity, since this water not only parts with its dissolved oxygen to the choanocytes at first encounters, but receives from them in exchange urea, carbonic acid, and fecal residues. The development of subdermal cavities is explicable on Von Lendenfeld's hypothesis.

Distribution

Distribution in space,

Our knowledge of this subject is at present but fragmentary, we await fuller information in the remaining reports on the sponges obtained by the "Challenger." The sponges are widely distributed through existing seas, and freshwater forms are found in the rivers and lakes of all continents except Australia, and in numerous islands, including New Zealand. Many genera and several species are cosmopolitan, and so are most orders.

As instances of the same species occurring in widely remote localities we take the following from Polejaeff—*Sycon arcticum* is found at the Bermudas and in the Philippine Islands, as also are *Leuconia multifurcata* and *Leucilla ulter*, *Sycon raphanus* occurs at Tristan da Cunha and the Philippines, *Heteropogon nodus goidii* and *Leuconia dura* at the Bermudas and Torres Straits. We do not know, however, whether these species are isolated in their distribution or connected by intermediate localities. Of the *Calcarea* about eighty-one species have been obtained from the Atlantic, twenty-two from the Pacific, and twenty-two from the Indian Ocean, but these numbers no doubt depend largely on the extent to which the several oceans have been investigated, for the largest number of species has been found in the ocean nearest home. Schulze states that the *Hexactinellida* brought home by the "Challenger" were obtained at seventeen Atlantic stations, twenty-seven Pacific, and nineteen in the South Seas. In the last the number of species was greatest, in the Atlantic least. They flourish best on a bottom of diatomaceous mud. The *Calcarea* and *Ceratosia* are most abundant in shallow water and down to 40 fathoms, but they descend to from 400 to 450 fathoms. The *Hexactinellida* are most numerous over continental depths, i.e., 100 to 200 fathoms, but they extend downwards to over 2500 fathoms and upwards into shallow water (10 to 20 fathoms). The *Lithistida* are not such deep water forms as the *Hexactinellida*, being most numerous from 10 to 150 fathoms. Only one or two species have been dredged from depths greater than 400 fathoms, and none from 1000 fathoms. The *Choristida* range from shallow water to abyssal depths. A characteristic deep sea Choristid genus is *Thenea*, Gray (= *Hyphilla Thompsonia*, Wright, *Dorvillea*, Kent). This is most frequently dredged from depths of from 1000 to 2000 fathoms, but it extends to 2700 fathoms on the one hand and to 100 on the other.

in time

Until about 1876 one of the chief obstacles to the inter-

pretation of fossil sponges arose from a singular mineral replacement which most of them have undergone, leading to the substitution of calcite for the silica of which their skeletons were originally composed. This change was demonstrated by Zittel (35) and Sollas (24), and, though it was at first pronounced impossible, owing to objections founded on the chemical nature of silica, it has since become generally recognized. These observers also showed that the fossil sponges do not belong to extinct types, but are assignable to existing orders. Zittel in addition subjected large collections to a careful analysis and marshalled them into order with remarkable success. Since then several palaeontologists have worked at the subject,—Pöcta, Dunkowski, and Hinde (7), who has published a *Catalogue*—which is much more than a catalogue—of the sponges preserved in the British Museum. The result of their labours is in general terms as follows. Fossil sponges are chiefly such as from the coarseness or consistency of their skeletons would be capable of preservation in a mineralized state. Thus the majority are *Hexactinellida*, chiefly *Dictyonina*, *Tetractinellida*, chiefly *Lithistida*, and *Calcarea*, chiefly *Leuconaria*. Monaxonid sponges rarely occur, the most ancient is *Climacopongia*, Hinde, found in Silurian rocks. A very common Halichondroid sponge of this group (*Phaetrospongia strahanii*, Soll) occurs in the Cambridge greensand, it owes its preservation to the collection of its small oxeate spicules into dense fibres. The *Choristida*, though not so common as the *Lithistida*, are commoner than the Monaxonids, particularly in Mesozoic strata.

The distribution of fossil sponges in the stratified systems may be summarized as follows. *Calcarea*—*Homocela*, none. *Heterocela*, a Syconid, in the Jurassic system. Numerous *Leuconaria* from the Devonian upwards. *Myospongia*—None, not fitted for preservation. *Hexactinellida*—*Lyssacina*, from the Lower Cambrian upwards. *Dictyonina*, commencing in the Silurian, most numerous in the Mesozoic group, still existing. *Monaxonida*—*Monaxon*, from the Silurian upwards. *Ceratosia*, none, few are fitted for preservation. *Tetractinellida*—*Choristida*, from the Carboniferous upwards, most numerous in the Cretaceous system. *Lithistida*, from the Silurian upwards, most numerous in the Mesozoic group. In ancient times the *Hexactinellida* and *Lithistida* seem not to have been so comparatively uncommon in shallow water as they are at the present day. Thus, in the Lower Jurassic strata of the south west of England we find *Dictyonina* *Hexactinellida*, *Lithistida*, and *Leuconaria* *Calcarea* associated together in a shelly breccia and in company with littoral shells, such as *Patella* and *Trochus*. Several Palaeozoic *Hexactinellida* actually occur in a fine grained sandstone. Of the Clark, which is the great mine of fossil sponges we must speak with caution, owing to the insufficient evidence as to the depth at which it was deposited.

As shown by *Protospongia*, the phylum of the sponges was in existence in very early Cambrian times, and probably much earlier. Before the end of the Silurian period its main branches had spread themselves out, and, developing fresh shoots since then, they have extended to the present day. Of the offshoots none of higher value than families are known to have become extinct, and of these decayed branches there are very few. The existence in modern seas of the *Asconida*, which must surely have branched off very near the base of the stem, is another curious instance of the persistence of simple types, which would thus appear not to be so vastly worse off in the struggle for existence than their more highly organized descendants.

Bibliography.—A fairly complete list of works on sponges published before 1882 will be found in Vosmaer's article "Porifera," in Bronn's *Klauseu und Ordnung*, vol. II. D'Arcy Thompson's *Catalogue of Papers on Protozoa and Ctenophora*, a still more complete list extends to 1884.

The following is a list of works, including those referred to in the preceding pages—(1) O. Barris, *Embryologie d quelques Eponges d Manche* Paris 1876. corals, is fatal. A favourable situation is a sheltered bay with a rocky bottom overgrown with green seaweed and freshened by gentle waves and currents. So favoured, the cuttings grow to a sponge two or three times their original size in one year, and at the end of five to seven years are large enough for the market. Similar experiments with similar results have more recently been carried on in Florida. The chief drawback to successful sponge farming would appear to be the long interval which the cultivator has to wait for his first crop.

Preparation for market

After the sponge has been taken from the sea, it is exposed to the air till signs of decomposition set in, and then without delay either beaten with a thick stick or trodden by the feet in a stream of flowing water till the skin and other soft tissues are completely removed. If this process is postponed for only a few hours after the sponge has been exposed a whole day to the air it is almost impossible to completely purify it. After cleaning it is hung up in the air to dry, and then with others finally pressed into bales. If not completely dried before packing the sponges "heat," orange yellow spots appearing on the parts attacked. The only remedy for this is to unpack

the bale and remove the affected sponges. The orange coloured spots produced by this "pest," or "cholera" as the Levant fishermen term it, must not be confounded with the brownish red colour which many sponges naturally possess, especially near their base. The sponges on reaching the wholesale houses are cut to a symmetrical shape and further cleaned. The light-coloured sponges often seen in chemists' shops have been bleached by chemical means which unpair their durability. Sponges are sold by weight, sand is used as an "adulteration."

It is difficult to obtain recent statistics as to the extent of the sponge trade, the following table gives a summary of the sponges sold in Trieste, the great European sponge market, in the year 1871—

Description of Sponge	For Export.		For Home Consumption	
	Value in £	Mean price per pound	Value in £	Mean price per pound
House sponge	£60,000	6s.	£4400	6s.
House sponge	20,000	1s.	500	6s.
House sponge	20,000	14s.	950	14s.
Fine Maltese sponge	2,000	8s.		

(W J S)

SPONSOR The presence of some suitable sponsor or sponsors to give the answers required and undertake the vows involved would seem to be almost essential to the right administration of the sacrament of baptism, in the case of infants at least. In this aspect, however, as in many others, the early history of the development of the rite of baptism remains obscure. The Greek word for the person undertaking this function is ἀδελφός, to which the Latin *sponsor* is equivalent. The word "sponsor" in this ecclesiastical sense occurs for the first time, but incidentally only, and as if it were already long familiar, in Tertullian's treatise *De Baptismo* (c. 18), where, arguing that in certain circumstances baptism may conveniently be postponed, especially in the case of little children, he asks, "For why is it necessary that the sponsors likewise should be thrust into danger, who both themselves by reason of mortality may fail to fulfil their promises, and may also be disappointed by the development of an evil disposition [in those for whom they become sponsors]?" There is nothing to make it unlikely that the sponsors here alluded to may have been in many cases the actual parents, and even in the 5th century it was not felt to be inappropriate that they should be so. Augustine, indeed, in one passage appears to speak of it as a matter of course that parents should bring their children and answer for them "tanquam fidei iussores" (*Epist. ad Bonif.*, 98). The comparatively early appearance, however, of such names as *compadres, comadres, propatres, promatres, patrini, matrinæ* is of itself sufficient evidence, not only that the sponsorial relationship had come to be regarded as a very close one, but also that it was not usually assumed by the natural parents. How very close it was held to be is shown by the Justinian prohibition of marriage between godparents and godchildren. On the other hand, the anciently allowable practice of parents becoming sponsors for their own children seems to have lingered until the 9th century, when it was at last formally prohibited by the council of Mainz (813). For a long time there was no fixed rule as to the necessary or allowable number of sponsors, and sometimes the number actually assumed was large. By the council of Trent, however, it was decreed that one only, or at most two, these not being of the same sex, should be permitted. The rubric of the Church of England according to which "there shall be for every male child to be baptized two godfathers and one godmother, and for every female one godfather and two godmothers," is not older than 1661, in the

Catechism the child is taught to say that he received his name from his "godfathers and godmothers." At the Reformation the Lutheran churches retained godfathers and godmothers, but the Reformed churches reverted to what they believed to be the more primitive rule, that in ordinary circumstances this function should be undertaken by a child's proper parents. All churches, it may be added, of course demand of sponsors that they be in full communion. In the Church of Rome priests, monks, and nuns are disqualified from being sponsors, either "because it might involve their entanglement in worldly affairs," or more probably because every relationship of fatherhood or motherhood is felt to be in their case inappropriate.

SPONTINI, GASPARO LUIGI PACIFICCO (1774-1851), dramatic composer, was born at Majolati (Ancona) in Italy, 14th November 1774, and educated at the Conservatorio de' Turchini at Naples under Sala, Tritto, and Saheri. After producing some successful operas at Rome, Florence, Naples, and Palermo, he settled in 1803 at Paris. His reception in the French capital was anything but flattering. His first comic opera, *Julie*, proved a failure, his second, *La Petite Maison*, was hissed. Undaunted by these misfortunes, he abandoned the light and somewhat frivolous style of his earlier works, and in *Milton*, a one-act opera produced in 1804, achieved a real success. Spontini henceforth aimed at a very high ideal, and during the remainder of his life strove so earnestly to reach it that he frequently remodelled his passages five or six times before permitting them to be performed in public, and wearied his singers by introducing new improvements at every rehearsal. His first masterpiece was *La Vestale*, completed in 1805, but kept from the stage through the opposition of a jealous clique until 15th December 1807, when it was produced at the Académie, and at once took rank with the finest works of its class. The composer's second opera, *Friedland*, was received with equal enthusiasm in 1809, but his third, *Olympia*, was much less warmly welcomed in 1819.

Spontini had been appointed in 1810 director of the Italian opera, but his quarrelsome and grasping disposition led to his summary dismissal in 1812, and, though reinstated in 1814, he voluntarily resigned his post soon afterwards. He was in fact very ill fitted to act as director, yet on 28th May 1820, five months after the failure of *Olympia*, he settled in Berlin by invitation of Frederick William III, commissioned to superintend all

music performed at the Prussian court and compose two new grand operas, or three smaller ones, every three years. But he began by at once embroiling himself with the intendant, Count Bruhl. Spontini's life at Berlin may be best described as a ceaseless struggle for precedence, under circumstances which rendered its attainment impossible in the sense in which he desired it. Yet he did good work, and did it well. *Die Vestalin*, *Ferdinand Cortez*, and *Olympia*—the last two entirely remodelled—were produced with great success in 1821. A new opera *Nourmahal*, founded on Moore's *Lalla Rookh*, was performed in 1822, and another, entitled *Alcidor*, in 1825, and in 1826 Spontini began the composition of *Agnes von Hohenstaufen*, a work planned on a grander scale than any of his former efforts. The first act was performed in 1827, and the complete work in three acts graced the marriage of Prince William in 1829. Though the German critics abused it bitterly, *Agnes von Hohenstaufen* is undoubtedly Spontini's greatest work. In breadth of conception and grandeur of style it exceeds both *Die Vestalin* and *Ferdinand Cortez*; and its details are worked out with untiring conscientiousness, yet Spontini was utterly dissatisfied with it, and at once set to work upon an entire revision, which on its representation in 1837 was in many parts scarcely recognizable by those who had heard the opera in its original form.

This was his last great work. He several times began to rewrite his early opera, *Milton*, and contemplated the treatment of many new subjects, such as *Sappho*, *La Cuisse d'Achille*, and other classical myths, but with no definite result. He had never been popular in Berlin, and he has been accused of endeavouring to prevent the performance of *Euryanthe*, *Oberon*, *Die Hochzeit des Camacho*, *Jessonda*, *Robert the Devil*, and other works of genius, through sheer envy of the laurels won by their composers. But the critics and reviewers of the period were so closely leagued together against him that it is difficult to know what to believe. After the death of Frederick William III. in 1840, Spontini's conduct became so violent and imperious that in 1842 Frederick William IV. dismissed him, with power to retain his titles and live wherever he pleased in the enjoyment of his full salary. He elected to settle once more in Paris, after a short visit to Italy, but beyond conducting occasional performances of some of his own works he made but few attempts to keep his name before the public. In 1847 he revisited Berlin and was invited by the king to conduct some performances during the winter. In 1848 he became deaf. In 1850 he retired to his birthplace, Majolati, and died there on 14th January 1851, bequeathing all he possessed to the poor of his native town.

SPOONBILL. The bird now so called was formerly known in England as the Shovelard or Shovelar, while that which used to bear the name of Spoonbill, often amplified into Spoon-billed Duck, is the SHOVELER (see vol. xxi. p. 842) of modern days—the exchange of names having been effected, as already stated (*loc cit*) about 200 years ago, when the subject of the present notice—the *Platalea leucorodia* of Linnaeus as well as of recent writers—was doubtless far better known than now, since it evidently was, from ancient documents, the constant concomitant of Herons, and with them the law attempted to protect it.¹ Mr Harting (*Zoologist*, 1886, pp. 81 *et seq*) has cited a case from the "Year-Book" of 14 Hen VIII. (1523),

¹ Nothing shows better the futility of the old statutes for the protection of birds than the fact that in 1534 the taking of the eggs of Herons, Spoonbills (Shovelars), Cranes, Bitterns, and Bustards was visited by a heavy penalty, while there was none for destroying the parent birds in the breeding season. All of the species just named, except the Heron, have passed away, while there is strong reason to think that some at least might have survived had the principle of the Levitical law (Deut. xxii. 6) been followed.

wherein the then bishop of London (Cuthbert Tunstall) maintained an action of trespass against the tenant of a close at Fulham for taking Herons and "Shovelars" that made their nests on the trees therein growing, and has also printed (*Zoologist*, 1877, pp. 425 *et seq*) an old document showing that "Shovelars" bred in certain woods in west Sussex in 1570. Nearly one hundred years later (*circa* 1662) Sir Thomas Browne, in his *Account of Birds found in Norfolk* (Works, ed. Wilkin, iv. pp. 315, 316), stated of the "Platea or Shovelard" that it formerly "built in the Hererie at Claxton and Reedham, now at Trimley in Suffolk." This last is the latest known proof of the breeding of the species in England, but more recent evidence to that effect may be hoped for from other sources. That the Spoonbill was in the fullest sense of the word a "native" of England is thus incontestably shown, but for many years past it has only been a more or less regular visitant, though not seldom in considerable numbers, which would doubtless, if allowed, once more make their home there, but its conspicuous appearance renders it an easy mark for the greedy gunner and the contemptible collector. What may have been the case formerly is not known, except that, according to Belon, it nested in his time (1555) in the borders of Brittany and Poitou, but as regards north-western Europe it seems of late years to have bred only in Holland, and there it has been deprived by drainage of its favourite resorts, one after the other, so that it must shortly become merely a stranger, except in Spain or the basin of the Danube and other parts of south-eastern Europe.

The Spoonbill ranges over the greater part of middle and southern Asia,² and breeds abundantly in India, as well as on some of the islands in the Red Sea, and seems to be resident throughout Northern Africa. In Southern Africa its place is taken by an allied species with red legs, *P. cristata* or *tenuirostris*, which also goes to Madagascar. Australia has two other species, *P. regia* or *melanorhynchus*, with black bill and feet, and *P. flavipes*, in which those parts are yellow. The very beautiful and wholly different *P. ajaja* is the Roseate Spoonbill of America, and is the only one found on that continent, the tropical or juxta-tropical parts of which it inhabits. The rich pink, deepening in some parts into crimson, of nearly all its plumage, together with the yellowish green of its bare head and its lake-coloured legs, sufficiently marks this bird, but all the other species are almost wholly clothed in pure white, though the English has, when adult, a fine buff pectoral band, and the spoon-shaped expanse of its bill is yellow, contrasting with the black of the compressed and basal portion. Its legs are also black. In the breeding season, a pendent tuft of white plumes further ornaments the head of both sexes, but is longest in the male. The young of the year have the primary quills dark coloured.

The Spoonbills form a natural group, *Plataleidae*, allied, as before stated (Ibis, vol. xii. p. 606), to the *Ibidae*, and somewhat more distantly to the Storks (see STORK),—all belonging to the *Pelargomorphæ* of Prof. Huxley. They breed in societies, not only of their own kind, but in company with Herons, either on trees or in reed-beds, making large nests in which are commonly laid four eggs,—white, speckled, streaked, or blotched, but never very closely, with light red. Such breeding-stations have been several times described, and among the more recent accounts of one of them are those of Messrs. Sclater and W. A. Forbes (*Ibis*, 1877, p. 412), and Mr. Seebohm (*Zoologist*, 1880, p. 457), while a view of another has been attempted by Schlegel (*Vog. Nederland*, taf. xvii.). The latest systematic revision of the group is by Dr. Reichenow (*Journ. für Ornithologie*, 1877, pp. 156-159), but his views have not been wholly accepted in the present article.

(A. N.)

² Ornithologists have been in doubt as to the recognition of two species from Japan described by Temminck and Schlegel under the names of *P. major* and *P. minor*. Lately it has been suggested that the former is only the young of *P. leucorodia*, and the latter the young of the Australian *P. regia*.

SPORADES, the islands "scattered" (as the name, from *σπαίρειν*, "to sow," imports) about the Greek Archipelago, are distinguished on the one hand from the Cyclades, which are grouped around Delos, and on the other from the islands attached, as it were, to the mainland of Europe and Asia. The distinction is not in either case a very definite one, and hence both ancient and modern writers differ as to the list of the Sporades. Details of classification are given by Bursian (*Griechenland*, ii 348 sq). The Doric Sporades—Melos (Μέλος),¹ Phologandrus, Siennus, Thira, Anaphe, Astypalaea, and Cos—were by some considered a southern cluster of the Cyclades. In modern times the name Sporades is more especially applied to two groups—the Northern Sporades, which lie north-east of Negropont (Euboea), along with which they constitute a nomarchy of the kingdom of Greece, and the Southern Sporades, lying off the south-west of Asia Minor, and included in the Turkish vilayet of the "Islands of the White Sea." The Northern, which have altogether an area of 180 square miles and a population of 13,394 (1879), comprise Skiatho, Khilodromi or Ilos, Skopelo, Pelagoussi, Gura, Pipari, and Skiro (Seynos), with their dependencies. The Southern are as follows—Icaria, Paros, Leros, Calymno, Astypalaea (Stamalia), Cos (Stanko), Nisyros, Tilos or Episcopi, Sime, Khalki, Rhodis, Creta, and a multitude of lesser isles.

SPORTS, THE BOOK OF, or more properly the DECLARATION OF SPORTS, was issued by James I in 1617 on the recommendation of Thomas Morton, bishop of Chester, for use in Lancashire, where the king on his return from Scotland found a conflict on the subject of Sunday amusements between the Puritans and the gentry, many of whom were Roman Catholics. Permission was given for dancing, archery, leaping, vaulting, and other harmless recreations, and of "having of May games, Whitsun ales, and morris dances, and the setting up of May-poles and other sports therewith used, so as the same may be had in due and convenient time without impediment or neglect of divine service, and that women shall have leave to carry rushes to church for the decorating of it." On the other hand, "bear and bull baiting, interludes, and (at all times in the mean sort of people by law prohibited) bowling" were not to be permitted on Sunday (Wilkins, *Concilia*, iv 483). In 1618 James transmitted orders to the clergy of the whole of England to read the declaration from the pulpit, but so strong was the opposition that he prudently withdrew his command (Wilson, in Kennet, ii 709, Fuller, *Church History*, i 452). In 1633 Charles I not only directed the republication of his father's declaration (Rushworth, ii 193) but insisted upon the reading of it by the clergy. Many of the clergy were punished for refusing to obey the injunction. With the fall of Laud all attempt to enforce it necessarily came to an end.

SPOTSWOOD, or SPOTTISWOOD, JOHN (1565-1639), archbishop of St Andrews, was the son of John Spotswood, minister of Calder and "superintendent" of Lothian, and was born in 1565. He was educated at Glasgow, and succeeded his father in the parish of Calder when but eighteen years of age. In 1601 he attended Ludowick, duke of Lennox, as his chaplain, in an embassy to the court of France, and returned in the duke's retinue through England. In 1603 he was nominated by the king to the see of Glasgow, but his consecration (in London) did not take place until October 1610. In 1615 he was translated as successor of Gladstones to St Andrews, and thus became primate and metropolitan of Scotland. In this capacity he presided in several assemblies of the Church of Scotland.

At that of Perth, in 1618, over which he presided, he used his influence to obtain a reluctant assent to the Five Articles. He continued in high esteem with James VI and Charles I, who was crowned by him in 1633 at Holyrood. In 1635 Spotswood was advanced to the chancellorship, but the increasing strength of the Covenanters compelled his resignation in 1638. He was deposed and excommunicated by the Glasgow assembly in that year, charges affecting his moral character were brought against him, but no attempt was made to substantiate these. He died in London on 26th December 1639 and was buried in Westminster Abbey.

In 1620 he published *Refutatio Libelli de Regimine Ecclesie Scotice*—an answer to a tract of Calderwood, who replied in the *Indicia* subjoined to his *Allare Damascenum*. The only other writing of Spotswood published during his lifetime was the sermon he preached at the Perth assembly. His most considerable work appeared posthumously—*The History of the Church and State of Scotland, beginning the year of our Lord 203 and continued to the end of the reign of James VI of ever blessed memory*, London, 1655, fol. It displays considerable research and sagacity, and even when dealing with contemporary events gives a favourable impression, upon the whole, of the author's candour and truth. An appendix was afterwards added by Thomas Middleton.

Spotswood left two sons,—Sir John Spotswoode of Dairsie in 1618, where the archbishop erected a church and bridge, which are still extant, and Sir Robert, a lawyer of great learning, who became president of the Court of Session, and was executed in 1646 for taking part in the expedition of Montrose.

SPOTTISWOODE, WILLIAM (1825-1883), mathematician and physicist, was born in London, 11th January 1825. His father, Andrew Spottiswoode, who was descended from an ancient Scottish family, represented Colchester in parliament for some years, and in 1831 became junior partner in the firm of Eyre & Spottiswoode, printers. William was educated at Laleham, Eton, Harrow, and Balliol College, Oxford. His bent for science showed itself while he was still a schoolboy, and indeed his removal from Eton to Harrow is said to have been occasioned by an accidental explosion which occurred whilst he was performing an experiment for his own amusement. At Harrow he obtained in 1842 a Lyon scholarship, and at Oxford in 1845 a first-class in mathematics, in 1846 the junior and in 1847 the senior university mathematical scholarship. In 1846 Spottiswoode left Oxford to take his father's place in the business, in which he was engaged until his death. In 1847 he issued five pamphlets entitled *Meditationes Analyticae*. This was his first publication of original mathematical work, and from this time scarcely a year passed in which he did not give to the world further mathematical researches. In 1856 Spottiswoode travelled in eastern Russia, and in 1860 in Croatia and Hungary, of the former expedition he has left an interesting record entitled *A Tarantasse Journey through Eastern Russia in the Autumn of 1856* (London, 1857). In 1870 he was elected president of the London Mathematical Society. In 1871 he began to turn his attention to experimental physics, his earlier researches bearing upon the polarization of light and his later work upon the electrical discharge in rarefied gases. He wrote a popular treatise upon the former subject for the "Nature" series (1874). In 1878 he was elected president of the British Association, and in the same year president of the Royal Society, of which he had been a fellow since 1853. He died of fever on 27th June 1883, and was buried in Westminster Abbey.

As a mathematician he occupied himself with many branches of his favourite science, more especially with higher algebra, including the theory of determinants, with the general calculus of symbols, and with the application of analysis to geometry and mechanics. The following brief review of his mathematical work is quoted from the obituary notice which appeared in the *Proceedings of the Royal Society* (vol. xxviii p 84)—"The interesting series of communications on the contact of curves and surfaces which are contained in the *Philosophical Transactions* of 1862 and

¹ The names of those Sporades which are treated under separate headings are printed in small capitals.

subsequent years would alone account for the high rank he obtained as a mathematician.

The mastery which he had obtained over the mathematical symbols was so complete that he never shrank from the use of expressions, however complicated—nay, the more complicated they were the more he seemed to revel in them—provided they did not run against the ruling spirit of all his work,—symmetry. To a mind imbued with the love of mathematical symmetry the study of determinants had naturally every attraction. In 1851 Mr Spottiswoode published in the form of a pamphlet an account of some elementary theorems on the subject. This having fallen out of print, permission was sought by the editor of *Crelle* to reproduce it in the pages of that journal. Mr Spottiswoode granted the request and undertook to revise his work. The subject had, however, been so extensively developed in the interim that it proved necessary not merely to revise it but entirely to rewrite the work, which became a memoir of 116 pages. To this, the first elementary treatise on determinants, much of the rapid development of the subject is due. The effect of the study on Mr Spottiswoode's own methods was most pronounced, there is scarcely a page of his mathematical writings that does not bristle with determinants. The Royal Society's *Catalogue of Scientific Papers* (vols. 1. viii.) shows a list of 49 papers by Spottiswoode, to which must be added about 66 more, the titles of which have not yet been printed in that catalogue. These were published principally in the *Philosophical Transactions*, *Proceedings of the Royal Society*, *Quarterly Journal of Mathematics*, *Proceedings of the London Mathematical Society*, and *Crelle*, and one or two in the *Comptes Rendus* of the Paris Academy. Another list of his papers, arranged according to the several journals in which they originally appeared, with short notes upon the less familiar memoirs, is given in *Nature*, vol. cxxii p. 599.

SPRAIN See **SURGERY**, p. 682, *infra*

SPRAT, a marine fish (*Clupea sprattus*), named "garvie" in Scotland, one of the smallest species of the genus *Clupea* or herrings, rarely exceeds 5 inches in length, and occurs in large shoals on the Atlantic coasts of Europe. It is found also in the southern hemisphere, on the coasts of Tasmania and New Zealand, where, however, it seems to be less abundant, since its presence at the antipodes has been discovered only recently, and it does not seem to be the object of a regular fishery. Sprats are very often confounded with young herrings, which they much resemble, but can always be distinguished by the following characters: they do not possess any teeth on the palate (*vomer*), like herrings, their gill covers are smooth, without the radiating striæ which are found in the shad and the pilchard, the anal fin consists of from seventeen to twenty rays, and the lateral line of forty seven or forty-eight scales. The ventral fins are even with the origin of the dorsal fin, and the spine consists of from forty-seven to forty-nine vertebrae. The sprat is one of the more important food-fishes on account of the immense numbers which are caught when the shoals approach the coasts. They are somewhat capricious, however, as regards the place and time of their appearance, the latter falling chiefly in the first half of winter. They are caught with the sein or with the bag-net in the tideway. Large quantities are consumed fresh, but many are pickled or smoked, and others prepared like anchovies. Frequently the captures are so large that the fish can be used as manure only.

SPREMBERG, a small town of Prussia, in the province of Brandenburg, is situated about 75 miles to the south-east of Berlin, partly on an island in the river Spree and partly on the west bank. It carries on considerable manufactures of woollen cloth, and has greatly advanced in importance and population since the beginning of the 19th century. In 1885 its population numbered 11,011. The only building of note is the *château*, built by a son of Elector John George about the end of the 16th century.

SPRENGEL, KURT (1766-1833), German botanist and physician, was born on 3d August 1766 at Boldekow in Pomerania. His father, a clergyman, provided him with a thorough education of wide scope, and the boy at an early age distinguished himself as a linguist, not only in Latin and Greek, but also in Arabic. He appeared as an author at the age of fourteen, publishing a small work

called *Anleitung zur Botanik für Frauenzimmer* in 1780. In 1784 he commenced in the university of Halle to study theology and medicine, but soon relinquished the former. He graduated in medicine in 1787. In 1789 he was appointed an extraordinary professor of medicine in his *alma mater*, and in 1795 was promoted to an ordinary professorship. He devoted much of his time to medical work and to investigations into the history of medicine, and he published several very valuable works in this department of knowledge, and made himself well known as one of the ablest medical men in Germany. He held a foremost rank in medicine and in botany as an original investigator, and in both published works of great value, besides numerous articles in scientific journals and in the proceedings of learned societies. His accomplishments as a linguist probably, in part at least, determined him in the choice of the department to which he most fully devoted himself, and in which he stood *facile princeps*. Among the more important of his many services to the science of botany was the part he took in awakening and stimulating microscopic investigation into the anatomy of the tissues of the higher plants, though defective microscopic appliances rendered the conclusions arrived at by himself unreliable. He also made many improvements in the details of both the Linnæan and the "natural" systems of classification. His life passed quietly at Halle in the pursuit of the studies dear to him, and in the enjoyment of the honours bestowed upon him by over seventy learned societies, and also by monarchs. In 1828 the death of a son, professor of surgery at Griefswald, was felt by him very severely. He experienced several apoplectic seizures, and died in one on 15th March 1833.

Subjoined is a list of the more important of his works:—*Beiträge zur Geschichte d. Pulses*, 1787, *Galens Fieberlehre*, 1788, *Apologie des Hippocrates*, 1789, *Versuch einer pragmatischen Geschichte der Arzneikunde*, 1792-99, *Handbuch der Pathologie*, 1795-97, *Institutiones Medicæ*, 1809-16 (in 6 vols.), *Geschichte der Medicin*, completed in 1820, *Antiquitatum botanicarum specimen*, 1798, *Historia rei herbariæ*, 1807-8, *Anleitung zur Kenntniss der Gewächse*, 1802-4, and again 1817-18, *Geschichte der Botanik*, 1817-18, *Von dem Bau und der Natur der Gewächse*, 1812, *Flora Halensis*, 1806-15, and in 1832, *Species umbelliferarum minus cognita*, 1818, *Neue Entdeckung im ganzen Umfang der Pflanzenkunde*, 1820-22. He edited an edition of Linnæus's *Systema vegetabilium* in 1824 and of the *Genera plantarum* in 1830. His short papers are too numerous to be quoted, a list of those in botany, from 1798 onwards, will be found in the Royal Society's *Catalogue of Scientific Papers*.

SPRINGBOK See **ANTELOPE**, vol. ii. p. 101

SPRINGFIELD, a city of the United States, capital of Illinois and the county seat of Sangamon county, 185 miles south-west of Chicago and 95 north-east of St. Louis, at the intersection of the main lines of the Chicago and Alton and the Wabash, St. Louis, and Pacific Railways. It is situated in 39° 48' N lat and 89° 33' W long, on a plateau 4 miles south of the Sangamon river. The State capitol (1868-1886) is constructed of Joliet marble in the form of a Greek cross, with porticos of granite, it is 385 feet long and 296 wide, and has a central dome surmounted by a lantern with a ball on the pinnacle (360 feet). It contains a general library, a law library, geological and agricultural museums, and a memorial hall of the Civil War, as well as the usual Government offices. Other buildings of note are the United States executive mansion, custom-house and post-office (1866-68), and the house formerly occupied by Lincoln. In Oak Ridge cemetery, adjacent to the city, is the Lincoln monument (1874), beneath which that president was buried. The monument, designed by Larkin G. Mead, consists of a granite obelisk, reaching a height of 98½ feet from the centre of a spacious basement (119½ feet long and 72½ wide), which contains a catacomb and a memorial hall,—the latter a museum of Lincolniana. A bronze statue of Lincoln and four groups

of figures in bronze, symbolizing the army and navy of the United States, are arranged round the foot of the obelisk. The town has a public library, two hospitals, two orphanages, and various other charitable institutions. Extensive deposits of bituminous coal occur in and near Springfield, which is the seat of extensive iron-rolling mills, watch factories, railway machine shops, plough works, and woolen, paper, and flom mills. It is also the headquarters of six of the principal live stock associations of the country. The population was 4533 in 1850, 9820 in 1860, 17,364 in 1870, 19,743 (1328 coloured) in 1880, and in 1887 it was estimated at 25,000.

Laid out in 1822, Springfield was selected as State capital in 1837, and was made a city in 1840.

SPRINGFIELD, a city of the United States, the county seat of Hampden county, Massachusetts, on the east bank of Connecticut river, opposite West Springfield, with which it is connected by road and railway bridges. By rail it is 98 miles west by south of Boston on the route to Albany, and it forms a very important railway junction. The western part of Springfield is built on low and level ground, the eastern on the ascent from the river valley. The streets are wide and well shaded with elm and maple. A United States arsenal (founded 1777) and armoury (1794), employing some 460 hands, is the largest in the republic. The Springfield breech-loading rifle of 45 calibre has been the regulation pattern in the United States army since 1873. A pistol-factory, car-works, manufactories of cotton and silk goods, buttons, needles, envelopes, paper, watches, skates, and brass work may be mentioned among the industrial establishments. The city hall (1855), a Romanesque building with an audience-room capable of holding 2700 persons, the city free library (1871), a Gothic building of brick, which contains 56,000 volumes and a museum, the granite court-house, the Roman Catholic cathedral of St Michael, Christ Church, Episcopal, the Church of the Unity, a fine Gothic structure in brown stone, the South Congregational church, the office of the Boston and Albany Railroad, a massive granite block, and the high school are among the chief architectural features of the city. Races are held in Hampden Park by the river side. The population was 15,199 in 1860, 26,703 in 1870, 33,340 in 1880 (775 coloured), and 37,577 in 1885.

Springfield was settled in 1636 by William Pynchon and emigrants from Roxbury,—the determination of the founder being to limit the "town" to forty or at most fifty families. The name was at first Agawam, but the present designation was adopted in 1641 in memory of Springfield (Essex), Pynchon's residence in his native country, England, to which he was obliged to return in 1652 to escape the clerical persecution called forth by his book on the *Meritorious Price of Christ's Redemption*. The town was burned by the Indians in 1675, and in 1787 the arsenal was attacked by Shays's rebels. The opening of the Boston and Albany Railroad in 1839 was the beginning of rapid development, and the town was made a city in 1852. The manufacture of firearms carried on here during the Civil War, 1861-65, gave the city a great impulse.

SPRINGFIELD, a city of the United States, county seat of Greene county, Missouri, occupies a pleasant and healthy site on the Ozark Hills, 238 miles by rail south-west of St Louis by the St Louis and San Francisco Railroad, which here joins with the Kansas City, Fort Scott, and Gulf Railroad. Springfield is the chief commercial centre of south-west Missouri, one of the great lead and zinc mining districts of the States. It contains a number of factories (cotton, wool, waggons, furniture, tobacco, &c), and is the seat of a court-house and of Drury College (1873), which provides scientific and classical training and has a musical conservatory attached. The population was 5555 in 1870, 6522 in 1880, and in 1886 was estimated at 18,000.

Originally an Indian trading post and frontier village, Springfield was incorporated in 1830 and began to be a prosperous place at the close of the Civil War, during which it had several times changed hands and been the scene of hostilities.

SPRINGFIELD, a city of the United States, county seat of Clarke county, Ohio, lies at the confluence of Mad river and Lagonda Creek (sub-tributaries of the Ohio through the Miami), 84 miles north-east of Cincinnati. It has a large trade in the agricultural produce of the fertile and populous district in which it is pleasantly situated, and is the seat of a very large manufactory of agricultural machinery, which turns out 75,000 reapers and mowers per annum, besides grain-drills, steam engines, cider-mills, and a great variety of articles. In 1870 the population of the city was 12,652, in 1880 20,730 (township, 24,455), and 33,484 in 1886. Among the public institutions are Wittenberg College (Lutheran), founded in 1845, and a small public library.

SPURZHEIM, KASPAR, phrenologist, was born at Longwich near Treves on 31st December 1776, and died at Boston, United States, on 10th November 1832. See **PHRENOLOGY**.

SQUARING (or QUADRATURE) OF THE CIRCLE is the problem of finding a square equal in area to a given circle. Like all problems, it may be increased in difficulty by the imposition of restrictions, consequently under the designation there may be embraced quite a variety of geometrical problems. It has to be noted, however, that, when the "squaring" of the circle is especially spoken of, it is almost always tacitly assumed that the restrictions are those of the Euclidean geometry.

Since the area of a circle equals that of the rectilinear triangle whose base has the same length as the circumference and whose altitude equals the radius (Archimedes, *Κύκλου μέτρησις*, prop. 1), it follows that, if a straight line could be drawn equal in length to the circumference, the required square could be found by an ordinary Euclidean construction, also, it is evident that, conversely, if a square equal in area to the circle could be obtained, it would be possible to draw a straight line equal to the circumference. Rectification and quadrature of the circle have thus been, since the time of Archimedes at least, practically identical problems. Again, since the circumferences of circles are proportional to their diameters—a proposition assumed to be true from the dawn almost of practical geometry—the rectification of the circle is seen to be transformable into finding the ratio of the circumference to the diameter. Thus correlative numerical problem and the two purely geometrical problems are inseparably connected historically.

Probably the earliest value for the ratio was 3. It was so among the Jews (1 Kings vii 23, 26), the Babylonians (Oppert, *Journ. Asiatique*, August 1872, October 1874), the Chinese (Biot, *Journ. Asiatique*, June 1841), and probably also the Greeks. Among the ancient Egyptians, as would appear from a calculation in the Rhind papyrus, the number $(\frac{256}{81})^2$, i.e., 3.16, was at one time in use.¹ The first attempts to solve the purely geometrical problem appear to have been made by the Greeks (Anaxagoras, &c),² one of whom, Hippocrates,³ doubtless raised hopes of a solution by his quadrature of the so-called *meniscus*. As for Euclid, it is sufficient to recall the facts that the original author of prop. 8 of book iv had strict proof of the ratio being <4 , and the author of prop. 15 of the ratio being >3 , and to direct attention to the importance

tion of the problem of rectification (see fig 2) ACB being a semicircle whose centre is O , and AC the arc to be rectified, he produced AB to D , making BD equal to the radius, joined DC , and produced it to meet the tangent at A in E , and then his assertion (not established by him) was that AE was nearly equal to the arc AC , the error being in defect. For the purposes of the calculator a solution erring in excess was also required, and thus Snell gave by slightly varying the former construction. Instead of producing AB

(see fig 3) so that BD was equal to r , he produced it only so far that, when the extremity D' was joined with C , the part of

Fig 3

$D'C$ outside the circle was equal to r , in other words by a non-Euclidean construction he trisected the angle AOC , for it is readily seen that, since $FD' = FO = OC$, the angle $FOB = \frac{1}{3}AOC$. This couplet of constructions is as important from the calculator's point of view as it is interesting geometrically. To compare it on this

Fig 4

score with the fundamental proposition of Archimedes, the latter must be put into a form similar to Snell's. AMC being an arc of a circle (see fig 4) whose centre is O , AC its chord, and HK the tangent drawn at the middle point of the arc and bounded by OA , OC produced, then, according to Archimedes, $AMC < HK$ but $> AC$. In modern trigonometrical notation the propositions to be compared stand as follows —

$$2 \tan \frac{1}{2}\theta > \theta > 2 \sin \frac{1}{2}\theta \quad (\text{Archimedes}),$$

$$\tan \frac{1}{2}\theta + 2 \sin \frac{1}{2}\theta > \theta > \frac{3 \sin \theta}{2 + \cos \theta} \quad (\text{Snell})$$

It is readily shown that the latter gives the best approximation to θ but, while the former requires for its application a knowledge of the trigonometrical ratios of only one angle (in other words, the ratios of the sides of only one right-angled triangle), the latter requires the same for two angles, θ and $\frac{1}{2}\theta$. Grienberger, using Snell's method, calculated the ratio correct to 39 fractional places². Huygens, in his *De Circuli Magnitudine Inventa*, 1654, proved the propositions of Snell, giving at the same time a number of other interesting theorems, for example, two inequalities which may be written as follows³—

$$\text{chd } \theta + \frac{4 \text{ chd } \theta - \sin \theta}{2 \text{ chd } \theta + 3 \sin \theta} \frac{1}{3} (\text{chd } \theta - \sin \theta) > \theta > \text{chd } \theta + \frac{1}{3} (\text{chd } \theta - \sin \theta)$$

As might be expected, a fresh view of the matter was taken by Descartes. The problem he set himself was the exact converse of that of Archimedes. A given straight line being viewed as equal in

length to the circumference of a circle, he sought to find the diameter of the circle. His construction is as follows (see fig 5). Take AB equal to one-fourth of the given line, on AB describe a square $ABCD$, join AC , in AC produced find, by a known process, a point C_1 such that, when C_1B_1 is drawn perpendicular to AB produced and C_1D_1 perpendicular to BC produced, the rectangle BC_1 will be equal to $\frac{1}{4}ABCD$. By the same process find a point C_2 such that the rectangle B_1C_2 will be equal to $\frac{1}{4}BC_1$, and so on *ad infinitum*. The diameter sought is the

Fig 5

¹ It is thus manifest that by his first construction Snell gave an approximate solution of two great problems of antiquity.

straight line from A to the limiting position of the series of B 's, say the straight line AB_{∞} . As in the case of the process of Archimedes, we may direct our attention either to the infinite series of geometrical operations or to the corresponding infinite series of arithmetical operations. Denoting the number of units in AB by $\frac{1}{2}$, we can express BB_1, B_1B_2, \dots in terms of $\frac{1}{2}$, and the identity $AB_{\infty} = AB + BB_1 + B_1B_2 + \dots$ gives us at once an expression for the diameter in terms of the circumference by means of an infinite series⁴. The proof of the correctness of the construction is seen to be involved in the following theorem, which serves likewise to throw new light on the subject— AB being any straight line whatever, and the above construction being made, then AB is the diameter of the circle circumscribed by the square $ABCD$ (self-evident), AB_1 is the diameter of the circle circumscribed by the regular 8-gon having the same perimeter as the square, AB_2 is the diameter of the circle circumscribed by the regular 16-gon having the same perimeter as the square, and so on. Essentially, therefore, Descartes's process is that known later as the process of *isoperimetry*, and often attributed wholly to Schwab⁵.

In 1655 appeared the *Arithmetica Infinitorum* of Wallis, where numerous problems of quadrature are dealt with, the curves being now represented in Cartesian coordinates, and algebra playing an important part. In a very curious manner, by viewing the circle $y = (1-x^2)^{\frac{1}{2}}$ as a member of the series of curves $y = (1-x^2)^{\frac{1}{2}}, y = (1-x^2)^{\frac{1}{3}}, \dots$, he was led to the proposition that four times the reciprocal of the ratio of the circumference to the diameter is equal to

$$\frac{3}{2} \frac{3}{4} \frac{5}{6} \frac{7}{8} \frac{9}{10} \dots$$

and the result having been communicated to Lord Brouncker, the latter discovered the equally curious equivalent expression

$$1 + \frac{1^2}{2} + \frac{3^2}{2} + \frac{5^2}{2} + \frac{7^2}{2} + \dots$$

The work of Wallis had evidently an important influence on the next notable personality in the history of the subject, James Gregory, who lived during the period when the higher algebraic analysis was coming into power, and whose genius helped materially to develop it. He had, however, in a certain sense one eye fixed on the past and the other towards the future. His first contribution was a variation of the method of Archimedes. The latter, as we know, calculated the perimeters of successive polygons, passing from one polygon to another of double the number of sides. In a similar manner Gregory calculated the arcs. The general theorems which enabled him to do this, after a start had been made, are

$$A_n = \sqrt{A_n' A_n''} \quad (\text{Snell's Cyclom.}),$$

$$A_n' = \frac{2 A_n' A_n''}{A_n' + A_n''} \text{ or } \frac{2 A_n' A_n''}{A_n' + A_n''} \quad (\text{Gregory}),$$

where A_n, A_n' are the areas of the inscribed and the circumscribed regular n -gons respectively. He also gave approximate rectifications of circular arcs after the manner of Huygens, and, what is very notable, he made an ingenious and, according to Montucla, successful attempt to show that quadrature of the circle by a Euclidean construction was impossible⁷. Besides all this, however, and far beyond its importance, was his use of infinite series. This merit he shares with his contemporaries Mercator, Newton and Leibnitz, and the exact dates of discovery are a little uncertain. As far as the circle squaring functions are con-

cerned, it would seem that Gregory was the first (in 1670) to make known the series for the arc in terms of the tangent, the series for the tangent in terms of the arc, and the secant in terms of the arc, and in 1669 Newton showed to Barrow a little treatise in manuscript containing the series for the arc in terms of the sine, for the sine in terms of the arc, and for the cosine in terms of the arc. These discoveries formed an epoch in the history of mathematics generally, and had, of course, a marked influence on after investigations regarding circle-quadrature. Even among the mere computers the series

$$\theta = \tan \theta - \frac{1}{3} \tan^3 \theta + \frac{1}{5} \tan^5 \theta - \dots,$$

specially known as Gregory's series, has ever since been a necessity of their calling.

The calculator's work having now become easier and more mechanical, calculation went on apace. In 1699 Abraham Sharp, on the suggestion of Halley, took Gregory's series, and, putting $\tan \theta = \frac{1}{3} \sqrt{3}$, found the ratio equal to

$$\sqrt{12} \left(1 - \frac{1}{3^3} + \frac{1}{5^3} - \frac{1}{7^3} + \dots \right),$$

from which he calculated it correct to 71 fractional places.¹ About the same time Machin calculated it correct to 100 places, and, what was of more importance, gave for the ratio the rapidly converging expression,

$$\frac{16}{5} \left(1 - \frac{1}{3^5} + \frac{1}{5^5} - \frac{1}{7^5} + \dots \right) - \frac{4}{239} \left(1 - \frac{1}{3^{239}} + \frac{1}{5^{239}} - \dots \right),$$

which long remained without explanation.² Fautet de Lagry, still using $\tan 30^\circ$, advanced to the 127th place.³

Euler took up the subject several times during his life, effecting mainly improvements in the theory of the various series.⁴ With him, apparently, began the usage of denoting by π the ratio of the circumference to the diameter.⁵ The most important publication, however, on the subject in the 18th century was a paper by Lambert,⁶ read before the Berlin Academy in 1761, in which he demonstrated the irrationality of π . The general test of irrationality which he established is that, if

$$\frac{a_1}{b_1} \pm \frac{a_2}{b_2} \pm \frac{a_3}{b_3} \pm \dots$$

be an interminate continued fraction, $a_1, a_2, \dots, b_1, b_2, \dots$

be integers, $\frac{a_1}{b_1}, \frac{a_2}{b_2}, \dots$ be proper fractions, and the value of every one of the interminate continued fractions $\frac{a_1}{b_1} \pm \frac{a_2}{b_2} \pm \dots$, be < 1 , then the given continued fraction represents an irrational quantity. If this be applied to the right-hand side of the identity

$$\tan \frac{m}{n} = \frac{m}{n} - \frac{m^3}{3n^3} + \frac{m^5}{5n^5} - \dots,$$

it follows that the tangent of every arc commensurable with the radius is irrational, so that, as a particular case, an arc of 45° , having its tangent rational, must be incommensurable with the radius, that is to say, $\frac{\pi}{4}$ is an incommensurable number. This incontestable result had no effect, apparently, in repressing the π -computers. Vega

in 1789, using series like Machin's, viz., Gregory's series and the identities

$$\frac{\pi}{4} = 5 \tan^{-1} \frac{1}{5} + 2 \tan^{-1} \frac{1}{239} \quad (\text{Euler, 1779}),$$

$$\frac{\pi}{4} = \tan^{-1} \frac{1}{2} + 2 \tan^{-1} \frac{1}{5} \quad (\text{Hutton, 1776}),$$

neither of which was nearly so advantageous as several found by Hutton, calculated — correct to 136 places.⁸ This achievement was anticipated or outdone by an unknown calculator, whose manuscript was seen in the Radcliffe Library, Oxford, by Baron von Zach towards the end of the century, and contained the ratio correct to 152 places. More astonishing still have been the deeds of the π -computers of the 19th century. A condensed record compiled by Mr Glaisher (*Messenger of Math.*, ii, p. 122) is as follows —

Date.	Computer	No. of fr. digits calcd.	No. of fr. digits correct	Place of Publication.

By these computers Machin's identity, or identities analogous to it, e.g.,

$$\frac{\pi}{4} = \tan^{-1} \frac{1}{2} + \tan^{-1} \frac{1}{5} + \tan^{-1} \frac{1}{8},$$

$$\frac{\pi}{4} = 4 \tan^{-1} \frac{1}{5} - \tan^{-1} \frac{1}{239} + \tan^{-1} \frac{1}{671},$$

and Gregory's series were employed.⁹

A much less wise class than the π -computers of the 19th century are the pseudo-circle squarers, or circle-squarers technically so called, that is to say, persons who, having obtained by illegitimate means a Euclidean construction for the quadrature or a finitely expressible value for π , insist on using faulty reasoning and defective mathematics to establish their assertions. Such persons have flourished at all times in the history of mathematics, but the interest attaching to them is more psychological than mathematical.¹⁰

It is of recent years that the most important advances in the theory of circle quadrature have been made. In 1873 Hermite proved that the base e of the Napierian logarithms cannot be a root of a rational algebraical equation of any degree.¹¹ To prove the same proposition regarding π is to prove that a Euclidean construction for circle quadrature is impossible. For in such a construction every point of the figure is obtained by the intersection of two straight lines, a straight line and a circle, or two circles, and, as this implies that, when a unit of length is introduced, numbers employed, and the problem transformed into one of algebraic geometry, the equations to be solved can only be of the first or second degree, it follows that the equation to which we must be finally led is a rational equation of even degree. Hermite¹² did not

succeed in his attempt on —, but in 1882 Landemann, following exactly in Hermite's steps, accomplished the desired result¹. Mathematicians are agreed that the full demonstration leaves something to be desired in the matter of simplicity, and attempts at simplification have already been made by Markoff and Ronchié².

SQUASH (*Cucurbita Mitopepo*) See GOURD

SQUILL, the name under which the bulbous root of *Urginea maritima*, Baker, is used in medicine. The plant was formerly placed in the genus *Scilla*, from which it has been separated because the seeds are flat and discoid instead of triquetrous, as in the latter genus. The name of "squill" is also applied by gardeners to the various species of *Scilla*. The medicinal squill is a native of the countries bordering the Mediterranean, and grows from the sea level up to an elevation of 3000 feet. The bulbs are globular and of large size, often weighing more than 1 lb. Two varieties are met with, the one having white and the other pink scales. They are collected in August, when they are leafless, the membranous outer scales being removed and the fleshy portion cut transversely into slices and dried in the sun. These are then packed in casks for exportation. They are chiefly imported into the United Kingdom from Malta. When reduced to powder and exposed to the air the drug rapidly absorbs moisture and cakes together into a hard mass. Squill has been used in medicine from a very early period. The ancient Greek physicians prescribed it with vinegar and honey almost in the same manner as it is used at present. Its medicinal properties are expectorant and diuretic. It is chiefly prescribed in bronchitis when the phlegm is tenacious and expectorated with difficulty, and in cardiac dropsy. When given in large doses it acts as an irritant poison, and its use is therefore contra-indicated in active inflammatory conditions of the mucous membrane of the kidneys. The fresh bulb rubbed on the skin causes redness and irritation, due in part to the presence of minute crystals of oxalate of calcium.

The activity of the drug appears to be due to the active principles, scillipern, scillitoxin, and scillin, which were first obtained by Merck in 1878. The first has a bitter and burning taste, powerfully irritating the mucous membrane of the nose. It is soluble in alcohol and ether and partly in alkalis, but insoluble in water, if mixed with sugar it dissolves readily and can then be absorbed if injected subcutaneously. Scillitoxin is hygroscopic, very soluble in water, and has a bitter taste. These two principles have an action on the heart resembling that of *Digitalis*, in large doses the former stops its action in systole and the latter in diastole. Scillin is crystalline, tasteless, and soluble in alcohol, though only with difficulty in water. It is present only in very small quantity in squill, and appears to be the cause of the subsidiary effects of that drug, such as vomiting, &c.

An allied species, *Urginea indica*, Baker, is used in India in the same manner as the European species. The true squills are represented in Great Britain by two species, *Scilla autumnalis* and *S. verna*. The former has a racemose inflorescence, the latter has the flowers arranged in a corymbose manner, and is confined to the seacoast. Several species are cultivated in gardens, *S. bifolia* and *S. verna* being remarkable for their beautiful blue flowers, which are produced in early spring. The name of Chinese squill is applied by gardeners to *Burmahia scilloides* and that of Roman squill to species of *Bellavalia*.

SQUINT See OPHTHALMOLOGY, vol. xvii p 785

SQUIRREL In the article MARMOT (vol. xv p 559) an account was given of the three genera forming the

Arctomys, or Marmot sub-family of the large family *Sciuridae*, and in the present article the members of the other and more typical sub-family, the *Sciurina*, are noticed. The systematic position of the *Sciurina* as a whole and their relations to other rodents are shown in the article MAMMALIA (vol. xi p 418), so it is merely with the component genera of the group that we now have to deal.

Of the *Sciurina* six genera are commonly recognized, the first being the typical one, *Sciurus*, in which the common English squirrel is included. The characters of the genus are—form slender and agile, tail long and bushy, ears generally well developed, pointed often tufted, feet adapted for climbing, the anterior pair with four toes and a rudimentary thumb, and the posterior pair with five toes, all the toes having long, curved, and sharp-pointed claws, mammae from four to six in number, skull (see fig. 1) lightly built, very similar in

FIG 1—Skull of *Sciurus hircolor*, natural size

shape throughout the genus, post-orbital processes long and curved, incisors narrow and compressed, premolars either one or two above and one below, when two are present above, the anterior one is quite minute and very different from the corresponding tooth in the marmots, molars three on each side above and below.

True squirrels are found throughout the greater part of the tropical and temperate regions of both hemispheres, although they are absent both from Madagascar and the Australian region. The species are both largest and most numerous in the tropics, and reach their greatest development in the Malay parts of the Oriental region.

Squirrels vary in size from animals no larger than a mouse, such as *Sciurus viciensis* of Borneo, or *S. minutus* of West Africa, to others as large as a cat, such as the black and yellow *S. hircolor* of Malaysia (see fig. 1). The very large squirrels, as might be expected from their heavier build, are somewhat less strictly arboreal in their habits than the smaller ones, of which the common English species may be looked upon as typical. The Common Squirrel, *S. vulgaris*, whose general habits are too well known to need special description, ranges over the whole of the Palearctic region, from Ireland to Japan, from Lapland to North Italy, but specimens from different parts of this wide range differ so much in colour as to have been often looked upon as different species. Thus, while the common squirrels of north and west Europe are of the bright red colour we are accustomed to see in England, those of the mountainous regions of southern Europe are nearly always of a deep blackish grey, those from Siberia again are a clear pale grey colour, with scarcely a tinge of rufous. These last supply the squirrel fur used for lining cloaks. The pairing time of the squirrel is from February to April, and after a period of gestation of about thirty days it brings forth from three to nine young. In addition to all sorts of vegetables and fruits the squirrel is exceedingly fond of animal food, greedily devouring mice, small birds, and eggs.

Although the English squirrel is a most beautiful little

¹ See "Ueber die Zahl π ," in *Math. Annalen*, ix p 213.

² *Ann. Math.*, 3d ser., ii p 5

a mammal, it is far surpassed by many of the tropical members of the group and especially by those of the Malayan region, where nearly all the numerous species are brilliantly marked and many are ornamented with variously coloured longitudinal stripes along their bodies. One of the commonest and best known of the striped species is the little Indian Palm Squirrel (*S. palmarum*) which in large numbers runs about every Indian village. Another Oriental species (*S. caniceps*) presents almost the only known instance among mammals of the temporary assumption during the breeding season of a distinctly ornamental coat corresponding to the breeding plumage of birds. For the greater part of the year the animal is of a uniform grey colour but about December its back becomes a brilliant orange yellow, which lasts until about March, when it is again replaced by grey. The squirrel shown in fig. 2 is a native of Burma and Tenasserim, and is

FIG. 2.—Burmese squirrel.

closely allied to *S. caniceps*, but goes through no seasonal change of colour.

The number of species in the genus *Sciurus* is about 75 of which 3 belong to the Palearctic, 15 to the Ethiopian, about 40 to the Oriental, and 16 to the combined Nearctic and Neotropical regions.

Genus Rheithrosciurus

A single very striking species of squirrel, confined to Borneo, and as yet only known from three or four examples, has been separated generically under the above name. The general shape of its skull is very different from that of other squirrels, but its most peculiar characteristic is the presence of from seven to ten minute parallel vertical grooves running down the front face of its incisor, both above and below, no other squirrel having really grooved incisors at all, and no other member of the whole order of rodents incisor grooves resembling these. Its premolars only number 3, and its molars are simpler and less ridged than in the other genera. This squirrel (*R. macrotis*) is a magnificent animal, far larger than the English species with an enormously long bushy tail, long tufted ear, and black and white bands down its sides.

Genus Xerus

Fur coarse and spinous. Claws long and comparatively straight. Ear coarse, minute or entirely absent. Skull with the post-orbital processes short and directed backwards, the lower palate prolonged considerably behind the tooth row, and the external ridge on the

front face of the anterior maxillary root more developed and continued much further upwards than in *Sciurus*. Premolars 7, molars as in *Sciurus*. This genus contains four well marked species known as Spiny Squirrels, all natives of Africa. They are terrestrial in their habits, living in burrows which they dig for themselves. *A. setulosus*, a striped species of North Africa, has much the size and appearance of the Indian palm squirrel, the others are all a little larger than the English squirrel.

Genus Tamias

The members of this genus are characterized by the possession of internal cheek pouches and by the 'V' of coloration, all being ornamented on the back with alternate bands of light and dark colour. Their skulls are slender and lighter than those of the true squirrels from which they differ in several important details. There is only one functional premolar—the small anterior one usually found in *Sciurus* being either lost or altogether small and functional. There are four species all found in North America one extending also through Siberia into eastern Europe. They are known in America as "Chipmunk," and are among the commonest and best known of the indigenous rodents. The members of this group seem rather to lead into the genus *Peromyscus* (see Murson) of the sub-family *Arctomys* so that the division of the *Sciurus* into two sub-families, although very convenient for classification and description is rather of an artificial nature there being no well-defined line of separation between them.

Genera Pteromys and Sciuropterus

The Flying Squirrels, although they cannot fly in the true sense of the word, can glide through the air for considerable distances by the aid of an extension of skin, one time, the fore and hind limbs, and forming a sort of parachute. This parachute is really a lateral extension of the ordinary skin of the body, which projects outwards between the limbs and terminates in a pair of small lobes. In addition to the lateral membrane there is a narrow and inconspicuous one joining from the chest along the front of the shoulder to the front of the vertebrae, and another one in the higher species—stretching across behind the body from ankle to ankle and involving the base of the tail. The flying squirrels are divided into two genera of which *Pteromys* contains the larger and *Sciuropterus* the smaller species. The two differ in the mode of dentition and in the great development in the former of the expanded membranes especially of the 'wing' or 'parachute' membrane which is in the latter almost wholly absent. In *Pteromys* the tail is cylindrical and comparatively long, while in *Sciuropterus* it is broad flat and broadly expanded at its base, it compensates for the absence of the most useful membrane by acting as a supplementary parachute. In appearance flying squirrels resemble the non flying forms although they are a somewhat differently coloured than the latter. Their habits too, are very similar to those of the true squirrels, except that they are more decidedly nocturnal and are therefore seldom seen by the ordinary observer. The method of leaping from tree to tree is similar to that of the flying phalangeres of Australia a graphic description of which is quoted in PHILADELPHIA VOL. XXIV p. 220. Of each of the two genera there are about thirteen or fourteen species, all natives of the Oriental region except that one of *Sciuropterus* is found in North America and another in Siberia and eastern Europe—the latter the *Sciuropterus* of Linnæus, *Sciurus* *Nat. rex* being the first flying squirrel that was known to European naturalists. (O. T.)

SRIRANGAM. See KASIMIR, vol. VII p. 11.

SRIRANGAM, or SRIRANGAM, a town of India in Trichinopoly district, Madras presidency, situated in 10° 51' 50" N lat and 78° 43' 55" E long. 2 miles north of Trichinopoly city and almost in the centre of the island of Srirangam. The island is formed by the bifurcation of the river Kaveri (Cauvery) and by the channel of the Coleroon. The town is celebrated for its great temple dedicated to Vishnu, composed of seven square enclosures, 350 feet distant from each other. Each enclosure has four gates with high towers, placed one in the centre of each side opposite to the four cardinal points. The outer wall of the temple is not less than 4 miles in circumference. From 1751 to 1755 the island and its pagodas were the object of frequent contests between the French and the British. Srirangam was constituted a municipality in 1871, and since then much has been done to improve the place. In 1881 the population was 19,773 (9330 males and 10,443 females).

SRIRANGAPATAM. See SEPINCAPATAM.

STAAL, MARCUFFITE JEANNE CORDIER DELAUNAY, BARONNE DE (1681-1750)—often called in history and literature Madame de Staal Delaunay, to distinguish her more completely from Madame de Stael Holstein—was born at Paris on May 30, 1684. Her father was a painter named Cordier. He seems to have deserted her mother, whose name was Delaunay, and who made her daughter take that surname instead of Cordier. She was well-educated, and entered the household of the Duchesse du Maine at Seauv, at first in no higher capacity than that of *femme de chambre*. She was, however, promoted before long to the office of amanuensis and (practically) companion to her mistress. Her literary talent soon manifested itself in the literary court of the duchess, who is said, but chiefly on the waiting lady's own authority, to have been not a little jealous of her attendant. Enough, however, is known of the duchess's imperious and capricious temper to make it improbable that her service was agreeable. Madame Delaunay, however, was a sufficiently devoted *survante*, and in the affair of the Cellamare conspiracy had to endure a visit to the Bastille, where she remained for two years. Even here, however, she represents herself as having made conquests, though she was far from beautiful. She returned on her liberation to the service of the duchess, refused, it is said, Dacier, the widower of a wife more famous than himself, and in 1735, being then more than fifty, married the Baron de Staal. She continued, however, to form part of the duchess's household. She died on June 16, 1750. Her *Memoirs* appeared about five years later, and have often been reprinted, both separately and in collections of the memoirs of the 17th and 18th centuries, to both of which the author belonged both in style and character. She has much of the frankness and seductive verve of Madame de Sévigné and her contemporaries, but a little alloyed with the *sensibilité* of a later time. It may be doubted whether she does not somewhat exaggerate the discomforts of her position and her sense of them. But her book is an extremely amusing one to read, as well as not a little instructive. The humours of the "court of Seauv" are depicted as hardly any other society of the kind has ever been. Besides her *Memoirs* Madame de Staal left two comedies and some letters, the answers to which are in some cases extant, and show, as well as the references of contemporaries, that the writer did not exaggerate her power of attracting men.

STADE, a small commercial town in the province of Hanover, Prussia, is situated on the navigable Schwinge, 31 miles above its confluence with the Elbe, and 20 miles to the north-west of Hamburg. It carries on a number of small manufactures and has some shipping trade, chiefly with Hamburg, but the rise of Harburg has deposed it from its former position as the chief port of Hanover. There are several brickfields in the neighbourhood, and deposits of gypsum and salt. The fortifications, erected in 1755 and strengthened in 1816, began to be demolished in 1882. Population in 1885, 10,003.

According to the legend, Stade was the oldest town of the Saxons and was built in 321 B.C. Historically it cannot be traced farther back than the 10th century, when it was the capital of a line of counts. In the 12th century it passed to the archbishopric of Bremen. Subsequently entering the Hanseatic League, it rose to some commercial importance. In 1648 Stade became the

capital of the principality of Bremen under the Swedes, and in 1719 it was ceded to Hanover, the fate of which it has since shared. The Prussians occupied it without resistance in 1866.

STAEL, MADAME DE (by her proper name and title ANNE LOUISE GERMAINE NECKER, BARONESS OF STAEL-HOLSTEIN), was born at Paris on April 22, 1766, and died there on July 14, 1817. Her father was the famous financier Necker, her mother Suzanne Curchod, who is almost equally famous as the early love of Gibbon, as the wife of Necker, as the mistress of one of the most popular salons of Paris, and as the mother of Madame de Stael. Between mother and daughter there was, however, little sympathy. Madame Necker, despite her talents, her beauty, and her fondness for *philosophic* society, was strictly decorous, somewhat reserved, and disposed to carry out in her daughter's case the rigorous discipline of her own childhood. The future Madame de Stael was from her earliest years a romp, a coquette, and passionately desirous of prominence and attention. There seems more over to have been a sort of rivalry between mother and daughter for the chief place in Necker's affections, and it is not probable that the daughter's love for her mother was increased by the consciousness of her own inferiority in personal charms. Madame Necker, if her portraits as well as verbal descriptions may be trusted, was of a most refined though somewhat lackadaisical style of beauty, while her daughter was a plain child and a plainer woman, whose sole attractions were large and striking eyes and a buxom figure. She was, however, a child of unusual intellectual power, and she began very early to write though not to publish. She is said to have written her father a letter on his famous *Compte Rendu* and other matters when she was not fifteen, and to have injured her health by excessive study and intellectual excitement. But in reading all the accounts of Madame de Stael's life which come from herself or her intimate friends it must be carefully remembered that she was the most distinguished and characteristic product of the period of *sensibilité*—the singular fashion of ultra sentiment which required that both men and women, but especially women, should be always palpitating with excitement, steeped in melancholy, or dissolved in tears. Still, there is no doubt that her father's dismissal from the ministry, which followed the presentation of the *Compte*, and the consequent removal of the family from the busy life of Paris, were beneficial to her. During part of the next few years they resided at Coppet, her father's estate on the Lake of Geneva, which she herself made famous. But other parts were spent in travelling about, chiefly in the south of France. They returned to Paris, or at least to its neighbourhood, in 1785, and Mademoiselle Necker resumed literary work of a miscellaneous kind, including two plays, *Sophie* and *Jane Grey*, which were printed sooner or later. It became, however, a question of marrying her. Her want of beauty was compensated by her fortune, for she was the only child of one of the richest bankers in Europe. But her parents are said to have objected to her marrying a Roman Catholic, which, in France, considerably limited her choice. There is a legend that William Pitt the younger thought of her, the somewhat notorious lover of Mademoiselle de Lespinasse, Guibert, a cold-hearted coxcomb of some talent, certainly paid her addresses. But she finally married Eric Magnus, Baron of Stael Holstein, who was first an attaché of the Swedish legation, and then minister. For a great heiress and a very ambitious girl the marriage scarcely seemed brilliant, for Stael had no fortune and no very great personal distinction. A singular series of negotiations, however, secured from the king of Sweden a promise of the ambassadorship for twelve years and a pension in case of

¹ The Stade Elbe dues (Stader Elbezoll) were an ancient impost upon all goods carried up the Elbe, and were levied at the village of Bruns hausen, at the mouth of the Schwinge. The tax was abolished in 1267 by the Hanseatic League, but it was revived by the Swedes in 1638, and confirmed by Hanover. The dues were fostered by the growing trade of Hamburg, and in 1861, when they were redeemed (for £427,600) by the nations trading in the Elbe, the exchequer of Hanover was in the yearly receipt of about £45,000 from this source. Hamburg and Great Britain each paid more than a third of the redemption money.

its withdrawal, and the marriage took place on January 14, 1786. The husband was thirty-seven, the wife twenty. Madame de Stael was accused of extravagance, and latterly an amicable separation of goods had to be effected between the pair. But this was a mere legal formality, and on the whole the marriage seems to have met the views of both parties, neither of whom had any affection for the other. They had three children, there was no scandal between them, the baron obtained money and the lady obtained, as a guaranteed ambassadress of a foreign power of consideration, a much higher position at court and in society than she could have secured by marrying almost any Frenchman, without the inconveniences which might have been expected had she married a Frenchman superior to herself in rank. The particular fancy of Marie Antoinette for Sweden, caused by the fantastic devotion of Count Fersen and the king himself to her, secured moreover a reception which might have been otherwise difficult to gain. Madame de Stael was not a *persona grata* at court, but she seems to have played the part of ambassadress, as she played most parts, in a rather noisy and exaggerated manner, but not ill. Then in 1788 she appeared as an author under her own name (*Sophie* had been already published, but anonymously) with some *Lettres sur J. J. Rousseau*, a fervid panegyric showing a good deal of talent but no power of criticism. She was at this time, and indeed generally, enthusiastic for a mixture of Rousseauism and constitutionalism in politics, and her father's restoration to power excited extravagant hopes in her, though Necker himself knew better. She exulted more than ever in the meeting of the states-general, and most of all when her father, after being driven to Brussels by a state intrigue, was once more recalled and triumphally escorted into Paris. Every one knows what followed. Her first child, a boy, was born the week before Necker finally left France in unpopularity and disgrace, and the increasing disturbances of the Revolution made her privileges as ambassadress no mere matters of ornamental distinction gratifying to vanity, but very important safeguards. She visited Coppet once or twice, but for the most part in the early days of the revolutionary period she was in Paris taking an interest and, as she thought, a part in the councils and efforts of the Moderates. At last, the day before the September massacres, she fled, befriended by Manuel and Tallien. Her own account of her escape is, as usual, so florid that it provokes the question whether she was really in any danger. Directly it does not seem that she was, but she had generously strained the privileges of the embassy to protect some threatened friends, and this was a serious matter.

She betook herself to Coppet, and there gathered round her a considerable number of friends and fellow-refugees, the beginning of the quasi-court which at intervals during the next five-and-twenty years made the place so famous. In 1793, however, she made a visit of some length to England, and established herself at Mickleham in Surrey as the centre of the Moderate Liberal emigrants, — Talleyrand, Narbonne, Jancourt, Gubert, and others. There was not a little scandal about her relations with Narbonne, and it is very much to be doubted whether this can safely be set down, as her panegyrists usually set it, to the mere spite of the first or royalist emigrants, to whom she and her party were almost more obnoxious than the Jacobins. It is certain that this Mickleham sojourn (the details of which are known from, among other sources, the letters of Fanny Burney) has never been altogether satisfactorily accounted for. In the summer she returned to Coppet and wrote a pamphlet on the queen's execution. The next year her mother died, and the fall of Robespierre opened the way back to Paris. M. de Stael (whose mis-

sion had been in abeyance and himself in Holland for three years) was accredited to the French republic by the regent of Sweden, his wife reopened her salon and for a time was conspicuous in the motley and eccentric society of the Directory. She also published several small works, the chief being an essay *De l'Influence des Passions* (1796), and another *De la Littérature Considérée dans ses Rapports avec les Institutions Sociales* (1800). It was during these years that Madame de Stael was of chief political importance. Narbonne's place had been supplied by Benjamin Constant, who had a very great influence over her, as in return she had over him. During the Directory she had some real and more imaginary power as a politician, and both personal and political reasons threw her into opposition to Bonaparte. Her own preference for a moderate republic or a constitutional monarchy was quite sincere, and, even if it had not been so, her own character and Napoleon's were too much alike in some points to admit of their getting on together. For some years, however, she was able to alternate between Coppet and Paris without difficulty, though not without knowing that the First Consul disliked her. In 1797 she, as above mentioned, separated formally from her husband. In 1799 he was recalled by the king of Sweden and in 1802 he died duly attended by her. Besides the eldest son Auguste Louis, they had two other children — a son Albert, and a daughter Albertine, who afterwards became the Duchesse de Broglie.

The exact date of the beginning of what Madame de Stael's admirers call her duel with Napoleon is not easy to determine. Judging from the title of her book *Dir Années d'Exil*, it should be put at 1804, judging from the time at which it became pretty clear that the first man in France and she who wished to be the first woman in France were not likely to get on together, it might be put several years earlier. The whole question of this duel, however (marked as it was by Napoleon's unscrupulous exercises of power, which reached a climax in the suppression of the *De l'Allemagne* after it had been carefully submitted to his censorship), requires consideration from the point of view of common sense. It displeased Napoleon no doubt that Madame de Stael should show herself recalcitrant to his influence. But it probably pleased Madame de Stael to quite an equal degree that Napoleon should apparently put forth his power to crush her and fail. Both personages had the curious touch of *charlatanerie* so common in the late 18th century, and "made believe" in a fashion bewildering and a little incredible to posterity. If Madame de Stael had really desired to take up her parable against Napoleon seriously, she need only have established herself in England at the peace of Amiens and have lived quietly there. She did nothing of the kind. She lingered on at Coppet, constantly hankering after Paris, and acknowledging the hankering quite honestly. In 1802 she published the first of her really noteworthy books, the novel of *Delphine*, in which the "femme incomprise" was in a manner introduced to French literature, and in which she herself and not a few of her intimates appeared in transparent disguise. In the autumn of 1803 she returned to Paris. Whether, if she had not displayed such extraordinary anxiety not to be exiled, Napoleon would have exiled her remains a question, but, as she began at once appealing to all sorts of persons to protect her, he seems to have thought it better that she should not be protected. She was directed not to reside within forty leagues of Paris, and after considerable delay she determined to go to Germany. She journeyed by Metz and Frankfort to Weimar, and arrived there in December. There she stayed during the winter, and then went to Berlin, where she

made the acquaintance of August Wilhelm Schlegel, who afterwards became one of her intimates at Coppet. Thence she travelled to Vienna, where, in April, the news of her father's dangerous illness and shortly of his death (April 8) reached her. She returned to Coppet, and found herself its wealthy and independent mistress, but her sorrow for her father was deep and certainly sincere. She spent the summer at the chateau with a brilliant company, in the autumn she journeyed to Italy accompanied by Schlegel and Sismondi, and there gathered the materials of her most famous work, *Corinne*. She returned in the summer of 1805, and spent nearly a year in writing *Corinne*, in 1806 she broke the decree of exile and lived for a time undisturbed near Paris. In 1807 *Corinne*, the first æsthetic romance not written in German, appeared. It is in fact, what it was described as being at the time of its appearance, "a picturesque tour couched in the form of a novel." The publication was taken as a reminder of her existence, and the police of the empire sent her back to Coppet. She stayed there as usual for the summer, and then set out once more for Germany, visiting Mainz, Frankfurt, Berlin, and Vienna. She was again at Coppet in the summer of 1808, and set to work at her book *De l'Allemagne*. It took her nearly the whole of the next two years, during which she did not travel much or far from her own house. She had bought property in America and thought of moving thither, but chance or fatality made her determine to publish *De l'Allemagne* in Paris. The submission to censorship which this entailed was sufficiently inconsistent, and she wrote to the emperor one of the unfortunate letters, at once undignified and provoking, of which she had the secret. A man less tyrannical or less mean spirited than Napoleon would of course have let her alone, but Napoleon was Napoleon, and she perfectly well knew him. The reply to her letter was the condemnation of the whole edition of her book (ten thousand copies) as "not French," and her own exile, not as before to a certain distance from Paris, but from France altogether. The act was unquestionably one of odious tyranny, but it is impossible not to ask why she had put herself within reach of it when her fortune enabled her to reside anywhere and to publish what she pleased. She retired once more to Coppet, where she was not at first interfered with, and she found consolation in a young officer of Swiss origin named Rocca, twenty three years her junior, whom she married privately in 1811. The intimacy of their relations could escape no one at Coppet, but the fact of the marriage was not certainly known till after her death.

The operations of the imperial police in regard to Madame de Stael are rather obscure. She was at first left undisturbed, but by degrees the chateau itself became taboo, and her visitors found themselves punished heavily. Mathieu de Montmorency and Madame Récamier were exiled for the crime of seeing her, and she at last began to think of doing what she ought to have done years before and withdrawing herself entirely from Napoleon's sphere. In the complete subjection of the Continent which preceded the Russian War this was not so easy as it would have been earlier, and she remained at home during the winter of 1811, writing and planning. On May 23 she left Coppet almost secretly, and journeyed by Bern, Innsbruck, and Salzburg to Vienna. There she obtained an Austrian passport to the frontier, and after some fears and trouble, receiving a Russian passport in Galicia, she at last escaped from the dungeon of Napoleonic Europe, swearing never to return thither. It seemed likely that the proclamation of war between France and Russia, on June 22, would help her to keep the vow.

She journeyed slowly through Russia and Finland to

Sweden, making some stay at St Petersburg, spent the winter in Stockholm, and then set out for England. Here she received a brilliant reception and was much lionized during the season of 1813. She published *De l'Allemagne* (a book much more really remarkable than *Corinne*) in the autumn, was saddened by the death of her second son Albert, who had entered the Swedish army and fell in a duel brought on by gambling, undertook her *Considérations sur la Révolution Française*, and when Louis XVIII. had been restored returned to Paris. Both in the summer and in the winter of 1814 she visited Coppet, and was meanwhile a prominent figure in Parisian society. She was in Paris when the news of Napoleon's landing arrived and at once fled to Coppet, but a singular story, much discussed, is current of her having approved Napoleon's return. There is no direct evidence of it, but the conduct of her close ally Constant may be quoted in its support, and it is certain that she had no affection for the Bourbons. In October, after Waterloo, she set out for Italy, not only for the advantage of her own health but for that of her second husband, Rocca, who was dying of consumption. Her daughter married Duke Victor de Broglie on February 20, 1816, at Pisa, and became the wife and mother of French statesmen of distinction. The whole family returned to Coppet in June, and Byron now frequently visited Madame de Stael there. He had quizzed her a good deal in London, but liked her better in her own house, though even there he noticed her constant straining to be something different from herself. Despite her increasing ill health she returned to Paris for the winter of 1816-17, and her salon was much frequented. But in March she is spoken of as "dying," and she had already become confined to her room, if not to her bed. She died on the 14th of July, and Rocca survived her little more than six months. Nor was her eldest son long lived. After editing a collected edition of his mother's works he died at the age of thirty-seven in 1827.

Madame de Stael occupies a singular position in French literature. The men of her own time exalted her to the skies, and the most extravagant estimates of her (as "the greatest woman in literary history," as the "foundress of the romantic movement," as representing "ideas," while her contemporary Chateaubriand only represented words, colours, and images, and so forth) are to be found in those histories of literature which faithfully repeat second hand and traditional opinions. On the other hand, it is acknowledged that she is now very little read. Sainte Beuve, who professes a "cult" for her, and who has treated her at great length and with much indulgence, M. Scherer, a compatriot and co-religionist, who is strongly prejudiced in her favour, Doucet, a kind of literary retainer of her connexions,—all allow this, and any one who speaks with an intimate knowledge of current French literature must agree that since they spoke neglect of her has increased. No writer of such prominence is so rarely quoted, none is so entirely destitute of that tribute of new and splendid editions which France pays to her favourite classics more lavishly than any other nation, none is so seldom the subject of a literary *causette*. The abundant documents in the hands of her descendants, the families of Broglie and Haussenville, have indeed furnished material for papers recently, but these are almost wholly on the social aspect of Madame de Stael, not on her literary merit. Nor when the life and works come to be examined independently is the neglect seen to be without excuse. An ugly coquette, an old woman who made a ridiculous marriage, a blue stocking who spent much of her time in pestering men of genius, and drawing from them sarcastic comment behind her back,—these things are not attractive. Her books are seen to be in large part merely clever reflexions of other people's views, or views current at the time, and the famous "ideas" turn out to be chiefly the ideas of the books or the men with whom she was from time to time in contact. The sentimentality of her sentiment and the florid magniloquence of her style equally disgust the reader, and, when it is suggested to him that the revolution of taste and manners hurts novels more than anything else, he is tempted to reply that it has not hurt *Don Quixote*, or *Gil Blas*, or *Robinson Crusoe*, or *Tom Jones*, or *Manon Lescaut*, or *The Antiquary*, and that if it has hurt *Corinne* it is simply because these are great books and *Corinne* is not a great book. There is truth in this, but to state it alone would be in the highest degree unfair. Madame de Stael's faults are great, her style is of an age not for

all time her ideas are mostly second hand and frequently superficial. But nothing save a very great talent could have shown itself so receptive. Take away her assiduous frequentation of society, from the later *philosophie* coteries to the age of Byron,—take away the influence of Constant and Schlegel and her other literary friends,—and probably little of her will remain. But to have caught from all sides in this manner the floating notions of society and of individuals, to reflect them with such vigour and clearness, to combine them with such not inconsiderable skill into connected books, is not anybody's task. Her two best books, *Corinne* and *De l'Allemagne*, are in all probability almost wholly unoriginal, a little sentiment in the first and a little constitutionalism in the second being all that she can claim. But *Corinne* is still a very remarkable exposition of a certain kind of æstheticism, and *De l'Allemagne* is still perhaps the most remarkable account of one country by a native and inhabitant of another which exists in literature. This praise, and it is very high praise, can be given to Madame de Staël. But the merits which it allows are not merits of the class which secure readers for ever. Neither in style nor in thought was she of the first class or perhaps of the second, and besides thought and style nothing will save books.

Baron Auguste de Staël edited as has been said the complete works of his mother in seventeen volumes (Paris, 1820-1) and the edition was afterwards republished in a compact form, and, supplemented by some *Œuvres inédites*, is still obtainable in 3 vols. large 8vo (Didot). The *Considerations* and the *De l'Année d'Art* had been published after Madame de Staël's death. There is no recent review of the whole and the minor works have not been reprinted, but *Corinne*, *Delphine* and *De l'Allemagne* are easily accessible in cheap and separate forms. Of recent works on Madame de Staël or rather on Coppet and its society those of M. Caro and Othenin d'Haussonville may be mentioned. In English there is an elaborate biography by A. Stevens (London 1889) full of information but unimpaired not at all critical.

VIII

STAFFORD, an inland county of England, is bounded on the SE by Warwickshire, S by Worcestershire, W by Shropshire, NW by Cheshire, and E by Derbyshire, just touching Leicestershire. It is of irregular outline, and has been likened to an elongated and compressed pear, somewhat tapering at both ends. Its greatest length from north to south is 53 miles, and its greatest breadth is 35 miles. The area is 748,433 acres—about 1170 square miles.

Surface and Geology—Although the general aspect of the county is that of a plain, it has been pronounced "rather a subalpine or hilly district", but its highest hill, Ake Edge, is only 1756 feet above the level of the sea. In the north the land is undulating and very picturesque, the hills here are the loftiest in the county, as Ake Edge, Cloud Thorpe, Mow Cop, and other hillocks and mounds called "edges". These are mostly composed of millstone grit. In the south we have sandstone, gravel, limestone, and basalt, represented respectively by Kinfares Edge, Barr and Cannock Chase, Sedgley, and Clent. The principal rivers are the Trent, the Tame, the Sow, the Penk, the Stour, the Blythe, the Tern, the Churnet, the Lyme, the Smestow, and the Manyfold, of these the Trent is the most important. The Severn has a short part of its course within the county, traversing the coal-field at Arley. The Dove separates Staffordshire from Derbyshire. Several of the rivers are well supplied with fish.

Geologically the county is included in the New Red Sandstone district of England, and is of the Carboniferous, Permian, and Triassic systems of formation. It is rich in limestone and coal. According to Mr Garner (*Natural History of the County of Stafford*) the following is a summary of its geological characters—the Polley coal field occupies 51 square miles, the South Staffordshire coal-field (excluding about 11 miles of it situated in other counties), 65, the Silurian limestone, &c., in the south of the county, 16, the Rowley basalt, 1, the Clent basalt, 2, the Arley coal field, basalt, cornstone, &c., 7, the mountain limestone, 40, the Cheddle coal field, 18, the Chiddleton coal field, 1, the Meerbrook coal field, 4, the millstone grit, 100, the New Red Sandstone (marl, gravel, rock, sand, and peat), 825.

The county is very rich in fossils. In the coal, the limestone, and the Silurian deposits the remains of marine animals and plants are especially numerous. The museums in several towns have good collections of corals, calamites,

and ferns, and probably the finest examples of trilobites and encrinurites have been found in this part of England. The teeth of the *Megahelthys* have been found in the coal strata, and the Dudley museum contains a specimen of *M. lubberti*, nearly entire. The county is very rich in mineral productions. In a single year 12,000,000 tons of coal and 1,173,866 tons of iron have been obtained. The greatest quantity of iron is raised in the north and of coal in the south. Of the places at which the various products are found may be named—Birch Hills for anthracite coal, Hanley Green for peacock coal, Longton for cannel coal, Wednesbury for hæmatite iron ore, Langley Close for grey marble, the Rowley Hills for basalt. At Bilston casting sand, at Kingswinford fire-clay and fire bricks, at Tutbury alabaster, at Powke Hill black marble, and at Hemley Green red ochre are produced. In December 1885 an important discovery of coal was made near Dudley. Mr S. Blewitt has driven from the Grace Mary pits about 250 yards towards the Ivy House estate, through the igneous rocks, and come upon a large area of the best hard coal, about thirty feet in thickness, and some thirty acres in area.

Climate and Agriculture—As regards climate the county shares the characteristics common to the midland district of England. Agriculture, though not its distinctive feature, forms a very important item in the industry and wealth of Staffordshire. The returns for 1886 furnish the following report: in corn crops there were 94,273 acres, roots, artificial grasses, &c., 43,343, clover and grasses, 46,832, permanent pasture, 412,566, fallow, 7203, orchards, 1188, market gardens, 866, nursery grounds, 233, woods and plantations, 34,911. From the same returns we learn that the number of horses employed in agriculture was 16,031, unbroken horses and brood mares, 7802, cows in milk or in calf, 74,868, cattle under two years old, 56,224, two years and upward, 25,922, one year old sheep, 142,955, sheep under one year, 106,950, and pigs, 48,569. The total number of proprietors in the county was returned in 1873 as 43,371, possessing 638,084 acres, producing an annual rental of £3,630,254. The estimated extent of waste or common land was 7809 acres. Of the owners 33,672 owned less than one acre each. Eight proprietors were owners of more than 10,000 acres each, viz., Earl of Lichfield, 21,433, Earl of Shrewsbury, 18,954, Lord Hatherton, 14,901, Marquis of Anglesey, 14,344, Sir J. H. Crewe, 14,256, Duke of Sutherland, 12,744, Lord Bagot, 10,993, Sir T. F. F. Boughay, 10,505.

Manufactures—The manufactures of Staffordshire are of a very varied character. Almost everything which is made of iron is manufactured in one town or another, and it would only be tedious to enumerate the almost infinite variety of goods produced. Wolverhampton and Willenhall are famous for locks, Cradley for nails, Oldbury for railway carriages, Walsall for spurs, bits, and saddlery, Tipton for anchors, Smethwick for glass, Soho for steam engines and hydraulic jacks, Wednesfield for keys, Bilston for tinplate wares, and Bloxwich for bits. Thanks to the labours of Josiah Wedgwood and Flaxman, the pottery work of Staffordshire ranks among the most famous manufactures of the kingdom, and Etruria is a household word wherever the admirable and artistic Wedgwood ware is known. The ale produced at Burton-on-Trent finds a market in almost every civilized country in the world, and in some that can scarcely be so described.

Communication—The county is admirably provided with railways, canals, and tramways. The main roads are excellent, and are well maintained and kept in capital condition.

Administration and Population—The population in 1861 was 746,943, in 1871 858,326, and in 1881 981,013 (males 492,009, females 489,004), an average of 1.31 persons to an acre. Staffordshire is in the Oxford circuit, and is nearly all in the diocese of Lichfield. The seat of the bishopric and the will courts are at Lichfield. The assize town is Stafford. There are five hundreds, each having two divisions—North Totmonslow (Leek) and South Totmonslow (Cheddle), North Pirehill (Potteries) and South Pirehill (Stone), North Offlow (Burton-on-Trent) and South Offlow (Walsall), East Cuttlestone (Rugeley) and West Cuttlestone (Gnosall), North Seisdon (Sedgley) and South Seisdon (Kinfares). The county has one court of quarter sessions, and is divided into twenty-two petty and special sessions divisions, and there are 247 civil parishes and sixteen poor law unions. The municipal boroughs number twelve—Burslem, population 26,522, Burton-on-Trent (partly in Derbyshire), 39,288, Hanley, 48,861, Lichfield, 8349, Longton, 18,620, Newcastle-under-Lyme, 17,508, Stafford, 19,977, Stoke-on-Trent, 19,261, Tamworth (partly in Warwickshire), 4891, Walsall 58,795, West Bromwich, 56,295, Wolverhampton, 75,766.

By the Redistribution of Seats Act, 1885, the parliamentary representation of Staffordshire was arranged as follows—seven boroughs each returning one member, one borough returning three, and seven county divisions with one member to each,—making seventeen members for the whole county. The county divisions are named respectively Burton, Handsworth, Kingswinford, Leek, Lichfield, North West, and West. The following is a list of the boroughs, with populations given by or based on the census of 1881—Wolverhampton (three members), 164,332, Hanley, 75,912, Newcastle under Lyme, 49,293, Stafford, 19,977, Stoke on Trent, 64,081, Walsall, 59,402, Wednesbury, 68,142, West Bromwich, 58,295.

History and Antiquities—Much antiquarian learning has been employed in showing that Staffordshire was in early ante Roman days famous for the presence and power of the Druids. Cannock Chase has been described as their headquarters in Britain, and Barr Beacon has been generally accepted as one of their principal places of worship, of which Dood or Druid Heath by its name still preserves the tradition. At the time of Caesar's arrival in the island this part of England was peopled by tribes whom the Roman authors designate as Cornavi or Carnabi. The conquerors named the central part of the country, which included Staffordshire, Flavia Caesariensis. Two of their most famous roads, Watling Street and Icknield Street, passed through the county,—the first named from Eazeley through Wall (*Floetum*) to Wrocester (*Ureconum*), and the Icknield Street through Birmingham to Wall, and by Burton on Trent to Dorby. In Saxon times Staffordshire formed part of the great kingdom of Mercia, which was remarkable for the tenacity with which the people clung to their old faith and resisted the introduction of Christianity. The new faith, however, prevailed over paganism and a cathedral was founded at Lichfield. Through the influence of Offa, Pope Adrian in 786 made the see an independent archbishopric, but this honour was only possessed for a short period. Mercia was frequently invaded by the Danes, and several battles were fought in Staffordshire, notably at Tettenhall and Wednesfield (Woden's Field), and a large number of Danes settled in this part. So rapidly did they occupy the land that in 1016, when the Danish king Canute divided his conquests into four earldoms, Mercia was believed to have as many Danish as Saxon inhabitants. After the Norman Conquest the county was divided among the Conqueror's retainers, the barons De Tori, De Montgomery, Fitz Anselm, and De Lincurs coming in for the lion's share. Of after historical events the most noted are the defeat and execution of the earl of Lancaster by Edward II in 1322, and the battle at Blore Heath in 1459, in which the Yorkists were victorious over the Lancastrians. During the Civil War Lichfield cathedral was besieged in 1643, and Lord Brook was killed by a shot fired from the battlements of the great tower. Mary queen of Scots was imprisoned in Tutbury Castle from 1569 to 1572. In 1745 Charles Edward, the Young Pretender, in his attempt to win the crown of England, penetrated as far as Leek.

Early British remains exist in various parts of the county, and a large number of barrows have been opened in which human bones, urns, fibulae, stone hammers, armlets, pins, pottery, and other articles have been found. In the neighbourhood of Wotton no fewer than twenty three barrows have been opened, and British ornaments have been found in Needwood Forest. Several Roman camps also exist in different parts. But of mediæval times the chief legacy is the cathedral at LICHFIELD (*q.v.*), one of the most beautiful in the kingdom. Of other interesting places the most worthy of notice are Beaudesert, Bentley Hall, Chillington, Dndley Castle, Fimble Hall, Ingestre, Stafford Castle, Tamworth Castle, Tixall, and Wrottesley Hall. More modern mansions are Ilam Hall, Alton Towers, Shugborough, Pateshall, Keele Hall, and Trentham. Of famous personages belonging to the county are John Dudley (duke of Northumberland), Cardinal Pole, Archbishop Sheldon, Col John Lane, General Harrison, Lord Anson, Earl St Vincent, Isaac Walton, Dr Samuel Johnson, David Garrick, Josiah Wedgwood, Miss Seward, Mary Howitt.

Langford, *Staffordshire and Warwickshire*, 1874, and the publications of the Salt Archaeological Society.

STAFFORD, a parliamentary and municipal borough of England and the county town of Staffordshire, is situated on the left bank of the river Sow, almost in the heart of England. It is 123 miles from London and 29½ from Birmingham, and is in the southern division of the hundred of Pirehill. The principal trades of the town are tanning and the manufacture of boots and shoes, more especially for ladies. The oldest church is that of St Chad, said to be originally of Saxon origin. It was formerly a large and beautiful church, with chancel, nave, aisles, transepts, and

a central tower, but has suffered severely from time, neglect, and rough treatment. Restoration was begun in 1855, and the operations led to the discovery of some fine interlacing Norman arches and a beautiful Norman archway with some rich sculptured work between the nave and tower. These were restored in 1856 and a new roof was put on the chancel in memory of Isaac Walton. In 1874, the nave, arcades, and open timbered roof were restored in memory of Mr Thomas Salt, in 1874–75 the south aisle was rebuilt, and in 1881–85 the tower. The finest of the churches in Stafford is undoubtedly St Mary's, which was admirably restored in 1844–45 by Sir Gilbert Scott, at a cost of £30,000. It contains some good monuments, and several very fine memorial windows of stained glass. Other churches worthy of mention are Christ Church, St Paul, and St Thomas's. The grammar school is a very old foundation, enlarged by Edward VI, the present building was erected in 1862. The free library was opened in 1882, and is now fairly well supplied with books. The William Salt library contains a unique collection of books, deeds, autographs, engravings, and drawings relating to the county, collected by Mr Salt and presented by his widow. It contains some 7000 volumes, between 2000 and 3000 deeds, and more than 9000 drawings, autographs, and valuable MSS, mostly relating to the history, topography, &c., of the county. The town also possesses a good museum, collected principally by Mr Clement L. Wragge, and called by his name, specially interesting is its almost perfect collection of fossils. Stafford also contains a good school of art and a mechanics' institute. Other prominent buildings are the shire hall, in which the assizes and quarter sessions are held, and the borough hall, the latter contains the municipal offices, and also has a large hall for public meetings. Stafford is well supplied with charitable institutions, among which may be mentioned the general infirmary, built in 1766, the county lunatic asylum in 1818, and the Coton Hill institution for the insane in 1854, beautifully situated on rising ground, which commands extensive views of some of the loveliest country in the county, while its own grounds are tastefully laid out. The householders of Stafford formerly possessed the right of using some very extensive common land situated north of the town, in 1880, however, all that remained (13½ acres) was enclosed, and is now held for the people by a committee of house holders elected annually. A part of this land, called Stone Flat, is preserved as a public recreation ground. Of another common named Coton Field, consisting of about 180 acres, 70 acres were in 1884 transferred absolutely to the freemen, and have been divided into 401 garden allotments, which are let at a small rental to resident freemen or their widows. The parliamentary borough (area 774 acres, with population of 18,901 in 1881) was extended in 1885, and is now identical with the municipal borough. The area of this is 1012 acres, and the population, 14,437 in 1871, was in 1881 19,977. The Act of 1885 reduced the parliamentary representation from two members to one.

Stafford was of considerable importance before the Conquest. The site was at first known as Bertelney or Bethenev, from the island on which the earliest houses were built. As the town grew its name was changed into that of Statford or Stadford. In 913 Ethelfleda, sister of Edward the Elder, erected a fortification here, generally called a castle, but doubtless one of those defensive mounds which from their admirable positions were afterwards selected by the Normans as the sites of their castles and strongholds. About a year and a half afterwards Edward the Elder built a tower, with walls and a fosse round it. Pannard says this was on the mount called Castle Hill by Speed. Stafford is mentioned in Domesday as a city paying £9 in customs. There were 18 royal burgesses and the earls of Mercia possessed twenty mansions. The number of houses entered is 178. William I built a castle on the old site, of which he appointed Robert de Torri

governor, who took the name De Stafford from that of the town, and was the originator of the great family of the Staffords. At this time it contained a royal mint, some of the coins are still extant, bearing on the obverse the head and name of the king, and on the reverse "Godwinne on Staef." Godwinne was the "king's moneyer." The castle of Robert de Torri was rebuilt by Ralph de Stafford in the reign of Edward III., during the Civil War it was held for the Royalists by the earl of Northampton, but was taken for the Parliament by Sir William Brereton in May 1643. The castle was soon afterwards demolished by order of the Parliament. When fortified, Stafford had four gates. That on the south, near the river bridge, called the Green gate, was taken down in 1780. The arch of the East gate was standing a few years ago. The Gaol gate was in ruins in 1680. The site of the fourth gate is unknown. King John confirmed and enlarged the privileges granted by the old charter. This was again confirmed by Edward VI., and on August 6, 1575, Elizabeth visited the town. Stafford adopted the Local Government Act, 1858, on April 23, 1872, and in 1876 an Act was obtained for extending the borough boundaries. The corporation now consists of a mayor, eight aldermen, and twenty-four councillors.

STAG. See DEER.

STAHL, GEORG ERNST (1660–1734), chemist, was born on 21st October 1660 at Ansbach, studied at Jena, and became court-physician to the duke of Weimar in 1687. In 1694 he was appointed professor of medicine in Halle and in 1716 physician to the king of Prussia. He died at Berlin on May 14, 1734. His *Theoria Medica Febris* appeared at Halle in 1707 (see MEDICINE, vol. xv p. 812), and his *Experimenta et Observationes Chemicæ* at Berlin in 1731 (see CHEMISTRY, vol. v pp. 460–61).

STAIR, JAMES DALRYMPLE, FIRST VISCOUNT (1619–1695), was born in May 1619 at Drummurchie in Ayrshire. He was descended from a family for several generations inclined to the principles of the Reformation, and had ancestors both on the father's and the mother's side amongst the Lollards of Kyle. His father James Dalrymple, laird of the small estate of Stair in Kyle, died when he was an infant, his mother, Janet Kennedy of Knockdaw, is described as "a woman of excellent spirit," who took care to have him well educated. From the grammar school at Mauchline he went in 1633 to the university of Glasgow, where he graduated in arts on July 26, 1637. Next year he went to Edinburgh, probably with the intention of studying law, but the troubles of the times then approaching a crisis led him to change his course, and we next find him serving in the earl of Glencairn's regiment in the war of the Covenant. What part he took in it is not certainly known, but he was in command of a troop when recalled in 1641 to compete for a regency (as a tutorship or professorship was then called) in the university of Glasgow. He was elected in March. Mathematics, logic, ethics, and politics were the chief subjects of his lectures, and a notebook on logic by one of his students has been preserved. His activity and skill in matters of college business were praised by his colleagues, who numbered amongst them some of the leading Covenanting divines, and his zeal in teaching was gratefully acknowledged by his students. After nearly seven years' service he resigned his regency, and removed to Edinburgh, where he was admitted to the bar on February 17, 1648. This step had probably been rendered easier by his marriage four years before to Margaret Ross, co-heiress of Balnail in Wigtown. Stair's practice at the bar does not appear to have been large, his talents lay rather in the direction of learning and business than of oratory or advocacy. His reputation and the confidence reposed in him were shown by his appointment in 1649 as secretary to the commission sent to The Hague to treat with Charles II. by the parliament of Scotland. The negotiation having been broken off through the unwillingness of the young king to accept the terms of the Covenanters, Stair was again sent in the following year to Breck, where the failure of Montrose's expedition forced Charles to change his attitude, and to return to

Scotland as the covenanted king. Stair had preceded him, and met him on his landing in Aberdeenshire, probably carrying with him the news of the execution of Montrose, which he had witnessed.

During the Commonwealth Stair continued to practise at the bar, but like most of his brethren he refused in 1654 to take the oath of allegiance to the Commonwealth and abjuration of royalty. Three years later, on the death of Lord Balcomie, Stair was appointed one of the commissioners for the administration of justice in Scotland on the recommendation of Monk. His appointment to the bench on 1st July 1657 by Monk was confirmed by Cromwell on the 26th. Stair's association with the English judges at this time must have enlarged his acquaintance with English law, as his travels had extended his knowledge of the civil law and the modern European systems which followed it. He thus acquired a singular advantage when he came to write on law, regarding it from a cosmopolitan or international rather than a merely local or national point of view. His actual discharge of judicial duty at this time was short, for after the death of Cromwell the courts in Scotland were shut,—a new commission issued in 1660 not having taken effect, it being uncertain in whose name the commission ought to run. It was during this period that Stair became intimate with Monk, who is said to have been advised by him when he left Scotland to call a full and free parliament. Soon after the Restoration Stair went to London, where he was received with favour by Charles, knighted, and included in the new nomination of judges in the Court of Session on 13th February 1661. He was also put on various important commissions, busied himself with local and agricultural affairs, and, like most of the Scottish judges of this and the following century, acted with zest and credit the part of a good country gentleman.

In 1662 he was one of the judges who refused to take the declaration that the National Covenant and the Solemn League and Covenant were unlawful oaths, and, forestalling the deposition which had been threatened as the penalty of continued non-compliance, he placed his resignation in the king's hands. The king, however, summoned him to London, and allowed him to take the declaration under an implied reservation. The next five years of Stair's life were comparatively uneventful, but in 1669 a family calamity, the exact facts of which will probably never be ascertained, overtook him. His daughter Janet, who had been betrothed to Lord Ruthcliff, was married to Dunbar of Baldoon, and some tragic incident occurred on the wedding night, from the effects of which she never recovered. As the traditions vary on the central fact, whether it was the bride who stabbed her husband, or the husband who stabbed the bride, no credence can be given to the mass of superstitious and spiteful slander which surrounded it, principally levelled at Lady Stair. In 1670 Stair served as one of the Scottish commissioners who went to London to treat of the Union, but the project, not seriously pressed by Charles and his ministers, broke down through a claim on the part of the Scots to what was deemed an excessive representation in the British parliament. In January 1671 Stair was appointed president of the Court of Session. In the following year, and again in 1673, he was returned to parliament for Wigtownshire, and took part in the important legislation of those years in the department of private law. During the bad time of Lauderdale's government Stair used his influence in the privy council and with Lauderdale to mitigate the severity of the orders passed against ecclesiastical offenders, but for the most part he abstained from attending a board whose policy he could not approve. In 1679 he went to London to defend the court against charges of partiality and injustice which had been made against it, and was

thanked by his brethren for his success. When in the following year the duke of York came to Scotland, Stair distinguished himself by a bold speech, in which he congratulated the duke on his coming amongst a nation which was entirely Protestant. This speech can have been little relished, and the duke was henceforth his implacable enemy. His influence prevented Stair from being made chancellor in 1681, on the death of the duke of Rothes.

The parliament of this year, in which Stair again sat, was memorable for two statutes, one in private and the other in public law. The former, relating to the testing of deeds, was drawn by Stair, and is sometimes called by his name. Although it is susceptible of some improvement, the two centuries during which it has regulated this important branch of practical conveyancing is a testimony to the skill of the draftsman. The other was the infamous Test Act, probably the worst of the many measures devised at this period with the object of fettering the conscience by oaths. Stair also had a minor share in the form which this law finally took, but it was confined to the insertion of a definition of "the Protestant religion", by this he hoped to make the test harmless, but his expectation was disappointed, and the form in which it emerged from parliament was such that no honest man could take it. Yet, self-contradictory and absurd as it was, the Test Act was at once rigidly enforced. Argyll, who declared he took it only in so far as it was consistent with itself and the Protestant religion, was tried and condemned for treason, and narrowly saved his life by escaping from Edinburgh Castle the day before that fixed for his execution. Stair, dreading a similar fate, went to London to seek a personal interview with the king, who had more than once befriended him, perhaps remembering his services in Holland, but the duke of York intercepted his access to the royal ear, and when he returned to Scotland he found a new commission of judges issued, from which his name was omitted. He retired to his wife's estate in Galloway, and occupied himself with preparing for the press his great work, *The Institutions of the Law of Scotland*, which he published in the autumn of 1681, with a dedication to the king.

He was not, however, allowed to pursue his legal studies in peaceful retirement. His wife was charged with attending conventicles, his factor and tenants severely fined, and he was himself not safe from prosecution at any moment. A fierce dispute arose between Claverhouse and his son, the master of Stair, relative to the regality of Glenluce, and, both having appealed to the privy council, Claverhouse, as might have been expected, was absolved from all the charges brought against him, and the master was deprived of the regality. Stair had still powerful friends, but his opponents were more powerful, and he received advice to quit the country. He repaired to Holland in October 1684, took up his residence, along with his wife, some of his younger children, and his grandchild, afterwards the field marshal Stair, at Leyden. While there he published the *Decisions of the Court of Session between 1666 and 1671*, of which he had kept a daily record, and a small treatise on natural philosophy, entitled *Physiologia Nova Experimentalis*.

In his absence a prosecution for treason was raised against him and others of the exiles by Sir G. Mackenzie, the lord advocate. He was charged with accession to the rebellion of 1679, the Ryehouse plot, and the expedition of Argyll. With the first two he had no connexion, with Argyll's unfortunate attempt he had no doubt sympathized, but the only proof of his complicity was slight, and was obtained by torture. The proceedings against him were never brought to an issue, having been continued by successive adjournments until 1687, when they were

dropped. The cause of their abandonment was the appointment of his son, the master of Stair, who had made his peace with James II., as lord advocate in room of Mackenzie, who was dismissed from office for refusing to relax the penal laws against the Catholics. The master only held office as lord advocate for a year, when he was "degraded to be justice clerk"—the king and his advisers finding him not a fit tool for their purpose. Stair remained in Holland till the following year, when he returned under happier auspices in the suite of William of Orange. William, who had made his acquaintance through the pensionary Fagel, was ever afterwards the firm friend of Stair and his family. The master was made lord advocate, and, on the murder of President Lockhart in the following year, Stair was again placed at the head of the Court of Session. An unscrupulous opposition, headed by Montgomery of Skelmorlie, who coveted the office of secretary for Scotland, and Lord Ross, who aimed at the presidency of the court, sprang up in the Scottish parliament, and an anonymous pamphleteer, perhaps Montgomery himself or Ferguson the Plotter, attacked Stair in a pamphlet entitled *The Late Proceedings of the Parliament of Scotland Stated and Vindicated*. He defended himself by publishing an *Apology*, which, in the opinion of impartial judges, was a complete vindication. Shortly after its issue he was created Viscount Stair. He had now reached the summit of his prosperity, and the few years which remained of his old age were saddened by private and public cares. In 1692 he lost his wife, the faithful partner of his good and evil fortune for nearly fifty years. The massacre of Glencoe, which has marked the master of Stair with a stain which his great services to the state cannot efface,—for he was undoubtedly the principal adviser of William in that treacherous and cruel deed,—was used as an opportunity, by his adversaries of renewing their attack on the old president. His own share in the crime was remote, it was alleged that he had as a privy councillor declined to receive Glencoe's oath of allegiance, though tendered, on the technical ground that it was omitted after the day fixed, but even this was not clearly proved. But some share of the odium which attached to his son was naturally reflected on him. Other grounds of complaint were not difficult to make up, which found willing supporters in the opposition members of parliament. A disappointed suitor brought in a bill in 1693 complaining of his partiality. He was also accused of domineering over the other judges and of favouring the clients of his sons. Two bills were introduced without naming him but really aimed at him,—one to disqualify peers from being judges and the other to confer on the crown a power to appoint temporary presidents of the court. The complaint against him was remitted to a committee, which after full inquiry completely exculpated him, and the two bills, whose incompetency he demonstrated in an able paper addressed to the commission and parliament, were allowed to drop. He was also one of a parliamentary commission which prepared a report on the regulation of the judicature, afterwards made the basis of a statute in 1695 supplementary to that of 1672, and forming the foundation of the judicial procedure in the Scottish courts down to the present century. On November 29, 1695, Stair, who had been for some time in failing health, died in Edinburgh, and was buried in the church of St Giles.

In the same year there was published in London a small volume with the title *A Vindication of the Divine Perfections, Illustrated in the Glory of God in them by Reason and Revelation, methodically digested,—By a Person of Honour*. It was edited by the two Nonconformist divines, William Bates and John Howe, who had been in exile in Holland along with Stair, and is undoubtedly his work. Perhaps it had been a sketch of the "Inquiry Concerning Natural Theology" which he had contemplated writing in 1681.

Oxford statute At the time of the Conquest Stamford was governed by alldermen. It was incorporated by charter in the reign of Edward IV. In 1663 it received a charter from Charles II, constituting its chief magistrate a mayor. It returned two members to parliament from the reign of Edward I till 1867, and one from 1867 to 1885. The dignity of Stamford is an ancient peculiar, the appointment being vested in the bishop of Lincoln.

STAMFORD, a borough of the United States, in Fairfield county, Connecticut, is situated on Long Island Sound, 35 miles north east of New York city, on the New York, New Haven, and Hartford Railroad. It has a small harbour accessible to steamboats by means of a canal, and among its public buildings are the town hall and several handsome churches. Locks, carriages, stoves, fire bricks, edge tools, cranes, hardware, hosiery, and especially log-wood extract and liquerice are manufactured in the borough. The population was 9714 in 1870 and 11,297 in 1880.

STAMMERING, or **STUTTERING**, designates a spasmodic affection of the organs of speech in which the articulation of words is suddenly checked and a pause ensues, often followed by a repetition in rapid sequence of the particular sound at which the stoppage occurred. Of this painful affection there are many grades, from a slight inability to pronounce with ease certain letters or syllables, or a tendency to hesitate and to interject unmeaning sounds in a spoken sentence, to the more severe condition in which there is a paroxysm of spasms of the muscles, not only of the tongue and throat and face, but even of those of respiration and of the body generally. To understand in some degree the explanation of stammering it is necessary to consider shortly the physiological mechanism of articulate speech. Speech is the result of various muscular movements affecting the current of air as it passes in expiration from the larynx through the mouth. If the vocal cords are called into action, and the sounds thus produced are modified by the muscular movements of the tongue, cheeks, and lips, we have vocal speech, but if the glottis is widely open and the vocal cords relaxed the current of air may still be moulded by the muscular apparatus so as to produce speech without voice, or whispering (see **VOICE**). In both cases, however, the mechanism is very complicated, requiring a series of nervous and muscular actions, all of which must be executed with precision and in accordance. In vocal speech, for example, it is necessary that the respiratory movements, more especially those of expiration, occur regularly and with nice adjustment to the kind of articulate expression required, that the vocal cords be approximated and tightened by the muscles of the larynx acting with delicate precision, so as to produce the sound of the pitch desired, that the *rima glottidis* (or aperture of the larynx) be opened so as to produce prolonged sounds, or suddenly closed so as to cut off the current of air, that the movements of the muscles of the tongue, of the soft palate, of the jaws, of the cheeks, and of the lips occur precisely at the right time and to the requisite extent, and finally that all of these muscular adjustments take place with rapidity and smoothness, gliding into each other without effort and without loss of time. Exquisite co-ordination of muscular movement is therefore necessary, involving also complicated nervous actions. Hence is it that speech is acquired by long and laborious effort. A child possesses voice from the beginning, it is born with the capacity for speech, but articulate expression is the result of education. In infancy, not only is knowledge acquired of external objects, and signs attached in the form of words to the ideas thus awakened, but the nervous and muscular mechanisms by which these signs or words receive vocal expression are trained by long practice to work harmoniously.

It is not surprising, therefore, that in certain cases,

owing to some obscure congenital defect, the co-ordination is not effected with sufficient precision, and that stammering is the result. Even in severe cases no appreciable lesion can be detected either in the nervous or muscular mechanisms, and the condition is similar to what may affect all varieties of finely co-ordinated movements. The mechanism does not work smoothly, but the pathologist is unable to shew any organic defect. Thus the co-ordinated movements necessary in writing are disturbed in scribblers' palsy, and the skilful performer on the piano or on any instrument requiring minute manipulation may find that he is losing the power of delicate adjustment. Stammering is occasionally hereditary. It rarely shows itself before the age of four or five years, and as a rule it is developed between this age and puberty. Men stammer in a much larger proportion than women. It may occur during the course of nervous affections, such as hysteria, epilepsy, or tabes dorsalis, sometimes it follows febrile disorders, often it develops in a child in a feeble state of health, without any special disease. In some cases a child may imitate a stammerer and thus acquire the habit. Any general enfeeblement of the health, and especially nervous excitement, aggravates the condition of a confirmed stammerer.

Stammerers, as a rule, find the explosive consonants *b*, *p*, *d*, *t*, *l*, and hard *g* the most difficult to articulate, but many also are unable easily to deal with the mere continuous consonants, such as *v*, *r*, *th*, *s*, *z*, *sh*, *m*, *n*, *g*, and in severe cases even the vowels may cause a certain amount of spasm. Usually the defect is not observed in whispering or singing, but there are exceptions to this statement. In pronouncing the explosive sounds the part of the oral apparatus that ought suddenly to open or close remains spasmodically closed, and the stammerer remains for a moment voiceless or strives pitifully to overcome the obstruction, uttering a few successive puffs or sounds like the beginning of the sound he wishes to utter. The lips thus remain closed at the attempted utterance of *b* and *p*, the tip of the tongue is pressed against the hard palate or the back of the upper front teeth in *d* and *t*, and the back of the tongue presses against the posterior part of the palate in pronouncing *g* hard and *l*. In attempting the continuous consonants, in which naturally the passage is not completely obstructed, the stammerer does not close the passage spasmodically, but the parts become fixed in the half opened condition, or there are intermittent attempts to open or close them, causing either a drawling sound or coming to a full stop. In severe cases, where even vowels cannot be freely uttered, the spasm appears to be at the *rima glottidis* (opening of the larynx). Again, in some cases, the spasm may affect the respiratory muscles, giving rise to a curious barking articulation, in consequence of spasm of the expiratory muscles, and in such cases the patient utters the first part of the sentence slowly, gradually accelerates the speed, and makes a rush towards the close. In the great majority of cases the spasm affects the muscles of articulation proper, that is, those of the pharynx, tongue, cheeks, and lips. In the most aggravated cases the condition of the patient is pitiable. It has thus been well described by Dr Bristow in an article full of interesting details—

"The most distressing cases are those in which the spasm extends to parts unconnected with speech,—it may be to nearly the whole muscular organism. In such a case the spasm commences, let us assume, at the base of the tongue, the mouth opens widely and remains in that position, the muscles of expiration work convulsively, the glottis contracts, respiration becomes arrested, the face becomes congested and the veins dilated, violent spasmodic movements involve the trunk and limbs, and only after some time, either when the patient becomes exhausted, or when he resolutely restrains his attempts to articulate, does his paroxysm come to an end."—*Quain's Dictionary of Medicine*, p. 1513.

Such a case is not common, it is more paroxysmal than habitual, and in ordinary conversation, when the patient is free from nervous excitement, the defect may be scarcely observed. A condition named *aphthongia* is even more distressing. It totally prevents speech, and may, at intervals, come on when the person attempts to speak, but fortunately it is only of temporary duration, and is usually caused by exceptional nervous excitement. It is characterized by spasm of the muscles supplied by the hypoglossal nerve, including the sterno-hyoid, sterno-thyroid, and thyro-hyoid muscles. In almost all cases of stuttering it is noticed that the defect is most apparent when the person is obliged to make a sudden transition from one class of sounds to another, and the patient soon discovers this for himself and chooses his words so as to avoid dangerous muscular combinations. When one considers the delicate nature of the adjustments necessary in articulate speech, this is what may be expected. It is well known that a quickly diffusible stimulant, such as alcohol, temporarily removes the difficulty in speech.

Stuttering may be successfully overcome in some cases by a careful process of education under a competent tutor. Not a few able public speakers were at first stutterers, but a prolonged course of vocal gymnastics has remedied the defect. The patient should be encouraged to read and speak slowly and deliberately, carefully pronouncing each syllable, and when he feels the tendency to stammer, he should be advised to pause for a short time, and then by a strong voluntary effort to attempt to pronounce the word. He should also be taught how to regulate respiration during speech, so that he may not fail from want of breath. In some cases aid may be obtained by raising the voice towards the close of the sentence. Sounds or combinations of sounds that present special difficulties should be made the subject of careful study, and the defect may be largely overcome by a series of graduated exercises in reading. The practice of intoning is useful in many cases. In ordinary conversation it is often important to have some one present who may by a look put the stammerer on his guard when he is observed to be talking too quickly or indistinctly. Thus by patience and determination many stammerers have so far overcome the defect that it can scarcely be noticed in conversation, but even in such cases mental excitement or slovenly inattention to the rules of speech suitable for the condition may cause a relapse. In very severe cases, where the spasmodic seizures affect other muscles than those of articulation, special medical treatment is necessary, as such are on the borderland of serious nervous disturbance. All measures tending to improve the general health, the removal of any affection of the mouth or gums that may aggravate habitual stammering, the avoidance of great emotional excitement, a steady determination to overcome the defect by voluntary control, and a system of education such as has been sketched will do much in the great majority of cases to remedy stammering.

(J G V)

STAMPS The stamp duty is a tax imposed upon a great variety of legal and other documents, and forms a branch of the national revenue. The stamp is a cheap and convenient mode of certifying that the revenue regulations have been complied with. Stamp duties appear to have been invented by the Dutch in 1624. They were first imposed in England in 1694 by 5 and 6 Will. and Mary, c. 21, as a temporary means of raising funds for carrying on the war with France. They now depend upon a very large number of statutes, the principal one being the Stamp Act, 1870, 33 and 34 Vict. c. 97 (which extends to the United Kingdom). The amount of stamp duty varies from one halfpenny (postage) to thousands of pounds (probate or succession). It appears scarcely

necessary in this place to set out at length the various stamp duties payable in the United Kingdom, inasmuch as those of the most usual occurrence will readily be found in ordinary books of reference.

Stamp duties are either fixed, such as the duty of one penny on every cheque irrespective of its amount, or *ad valorem*, as the duty on a conveyance, which varies according to the amount of the purchase money. The duty is denoted generally by an impression, less frequently by an adhesive stamp, sometimes by either at the option of the person stamping. Thus an inland bill of exchange (unless payable on demand) must have an impressed stamp, a foreign bill of exchange an adhesive stamp, while an agreement or receipt stamp may be of either kind. It should be noticed that certain documents falling within a class which as a rule is subject to stamp duty are for reasons of public policy or encouragement of trade exempted from the duty by special legislation. Examples of such documents are Bank of England notes, agreements within £ 17 (but not those within £ 4) of the Statute of Frauds (see F. & F.), agreements between a master of a ship and his crew, transfer of ships or shares in ships, indentures of apprenticeship for the sea service, petitions forwarded by post to the crown or a House of Parliament, and most instruments relating to the business of building and friendly societies.

As a general rule a document must be stamped at the time of execution, or a penalty (recoverable by the commissioners of inland revenue) is incurred. The penalty is in most cases £10, sometimes much more, in the case of policies of marine insurance it is £100. Some instruments cannot be stamped at all after execution, even with payment of the penalty. Such are bills of exchange and promissory notes (where an impressed stamp is necessary), bills of lading, proxies for voting at meetings of proprietors of joint stock companies, and receipts after a month from date. An unstamped instrument cannot be pleaded or given in evidence except in criminal proceedings or for a collateral purpose. If an instrument chargeable with duty be produced as evidence in a court, the officer who admits it is to read the instrument is to call the attention of the judge to any omission or insufficiency of the stamp; and if the instrument is one which may legally be stamped after execution, it may, on payment of the amount of the unpaid duty and the penalty payable by law, and a further sum of £1, be received in evidence, saving all just exceptions on other grounds. The rules of the Supreme Court, 1883 (Ord. xxxv. r. 6, enacting a provision of the Common Law Procedure Act), provide that a new trial is not to be granted by reason of the ruling of a judge that the stamp upon any document is sufficient or that the document does not require a stamp. The stamp upon a document subject to the stamp laws of a foreign state is usually admissible in evidence in a court of the United Kingdom if it conforms in other respects to the rules governing the admissibility of such documents, even though it be improperly stamped according to the law of the foreign country. The admissibility of documents belongs to the *ordinat rati* *lis* rather than the *decuria lis*, and is governed by the *locus* rather than the *locus contractus*, unless indeed that law makes a stamp necessary to the validity of the instrument. As to bills of exchange, the Bills of Exchange Act, 1882, 45 and 46 Vict. c. 61, § 72, provides that where a bill is issued out of the United Kingdom it is not invalid by reason only that it is not stamped in accordance with the law of the place of issue, and that where a bill issued out of the United Kingdom conforms as regards requisites in form to the law of the United Kingdom it may for the purpose of enforcing payment thereof be treated as valid as between all persons who negotiate, hold, or become parties to it in the United Kingdom.

By the Stamp Duties Management Act, 1870, 33 and 34 Vict. c. 98, the stamp duties are put under the management of the commissioners of inland revenue, who are empowered to grant licences to deal in stamps, and to make allowance for spoiled or misused stamps. Certain offences, such as forging a die or stamp, selling or using a forged stamp, &c., are made felonies punishable with penal servitude for life as a maximum.

United States—The subject of stamp duties is of unusual historical interest, as the passing of Granville's Stamp Act of 1765 (5 Geo. III. c. 12) directly led to the American revolution. The Act was, indeed, repealed the next year as a matter of expediency by 6 Geo. III. c. 11, but 6 Geo. III. c. 12 declared the right of the British legislature to bind the colonies by its Acts. The actual yield of the stamp duties under the Act of 1765 was, owing to the opposition in the American colonies, only £4000—less than the expenses of putting the Act into force. The stamp duties of the United States are now under the superintendence of the commissioner of internal revenue. These duties, which depend upon a great body of statutory law, will be found in the Revised Statutes, tit. xxvi.

The principal authorities on the subject of this article are Tilsley, *Stamp Laws*, and Dowell, *Stamp Duties*.

STANDARDS See WEIGHTS AND MEASURES.

STANFIELD, WILLIAM CLARKSON (1794–1867), marine painter, was born of Irish parentage at Sunderland in 1794. As a youth he was a sailor, and during many long voyages he acquired that intimate acquaintance with the sea and shipping which was admirably displayed in his subsequent works. In his spare time he diligently occupied himself in sketching marine subjects, and so much skill did he acquire that, after having been incapacitated by an accident from active service, he received an engagement, about 1818, to paint scenery for the "Old Royalty," a sailor's theatre in Wellclose Square, London. Along with David Roberts he was afterwards employed at the Cobourg theatre, Lambeth, and in 1826 he became scene painter to Drury Lane theatre, where he executed some admirable work, especially distinguishing himself by the production of a drop scene, and by decorations for the Christmas pieces for which the house was celebrated. Meanwhile he had been at work upon some easel pictures of small dimensions, and was elected a member of the Society of British Artists. Encouraged by his success at the British Institution, where in 1827 he exhibited his first important picture—*Wrecker off Port Rouge*—and in 1828 gained a premium of 50 guineas, he before 1830 abandoned scene painting, and in that year made an extended tour on the Continent. He now produced his *Mount St Michael*, which ranks as one of his finest works, in 1832 he exhibited his *Opening of New London Bridge and Portsmouth Harbour*—commissions from William IV—in the Royal Academy, of which he was elected an associate in 1832 and an academician in 1835, and until his death on the 18th of May 1867 he contributed to its exhibitions a long series of powerful and highly popular works, dealing mainly with marine subjects, but occasionally with scenes of a more purely landscape character.

Among these may be named—the *Battle of Trafalgar* (1836), executed for the United Service Club, the *Castle of Ischia* (1841), *Isola Bella* (1841), among the results of a visit to Italy in 1839, *French Troops Fording the Magra* (1847), the "*Victory*" bearing the *Body of Nelson Towed into Gibraltar* (1853), the *Abandoned* (1856). He also executed two notable series of Venetian subjects, one for the banquet hall at Bowood, the other for *Trentham*. He was much employed on the illustrations for *The Picturesque Annual*, and published a collection of lithographic views on the Rhine, Moselle, and Meuse, and forty of his works were engraved in line under the title of "*Stanfield's Coast Scenery*." Four of his engraved pictures are in the National Gallery, and his works may also be studied in the South Kensington Museum. A large collection of his productions were included in the Royal Academy's Winter Exhibition for 1870. The whole course of Stanfield's art was powerfully influenced by his early practice as a scene painter. But, though there is always a touch of the spectacular and the scenic in his work, and though their colour is apt to be rather dry and hard, they are large and effective in handling, powerful in their treatment of broad atmospheric effects, and telling in composition, and they evince the most complete knowledge of the artistic materials with which their painter dealt.

STANHOPE, CHARLES STANHOPE, THIRD EARL (1753–1816), was born on 3d August 1753, and educated under the opposing influences of Eton and Geneva, devoting himself whilst resident in the Swiss city to the study of mathematics, and acquiring from the associations connected with Switzerland an intense love of liberty. He contested the representation of the city of Westminster without success in 1771, when only just of age, but from the general election of 1780 until his accession to the peerage on the 7th of March 1786 he represented through the influence of Lord Shelburne the Buckinghamshire borough of High Wycombe, and during the sessions of 1783 and 1784 he gave his support to the administration of William Pitt, whose sister Lady Hester Pitt he married on 19th December 1774. When Pitt ceased to be inspired by the Liberal principles of his early days, his brother-in-law severed their political connexion and opposed with all

the impetuosity of his fiery heart the arbitrary measures which the ministry favoured. Lord Stanhope's character was without any taint of meanness, and his conduct was marked by a lofty consistency never influenced by any petty motives, but his speeches, able as they were, had no weight on the minds of his compeers in the upper chamber, and, from a disregard of their prejudices, too often drove them into the opposite lobby. He was the chairman of the "Revolution Society," founded in honour of the Revolution of 1688, the members of which in 1790 expressed their sympathy with the aims of the French republicans. He brought forward in 1794 the case of Muir, one of the Edinburgh politicians who were transported to Botany Bay, and in 1795 he introduced into the Lords a motion deprecating any interference with the internal affairs of France. In all of these points he was hopelessly beaten, and in the last of them he was in a "minority of one"—a sobriquet which stuck to him throughout life,—whereupon he seceded from parliamentary life for five years. The lean and awkward figure of Lord Stanhope figured in a host of the caricatures of Sayers and Gillray, reflecting on his political opinions and his personal relations with his children. His first wife died on 20th July 1780, and he married on 17th March 1781 Louisa, daughter and sole heiress of the Hon. Henry Grenville (governor of Barbados in 1746 and ambassador to the Porte in 1762), a younger brother of the first Earl Temple and George Grenville. Through his union with this lady, who survived until March 1829, he was doubly connected with the family of Grenville. By his first wife he had three daughters, one of whom was Lady Hester Stanhope (see below), and his second wife was the mother of three sons. Lord Stanhope died at the family seat of Chivening, Kent, on 15th December 1816.

Earl Stanhope was elected a fellow of the Royal Society so early as November 1772, and devoted a large part of his income to experiments in science and philosophy. He invented a method of securing buildings from fire (which, however, proved impracticable), the printing press and the lens which bear his name, and a monochord for tuning musical instruments, suggested improvements in canal locks, made experiments in steam navigation in 1795–97, and contrived two calculating machines. When he acquired an extensive property in Devonshire, he projected a canal through that county from the Bristol to the English Channel and took the levels himself. Electricity was another of the subjects which he studied, and the volume of *Principles of Electricity* which he issued in 1779 contained the rudiments of his theory on the "return stroke" resulting from the contact with the earth of the electric current of lightning, which were afterwards amplified in a contribution to the *Philosophical Transactions* for 1787. His principal labours in literature consisted of a reply to Burke's *Reflections on the French Revolution* (1790) and an *Essay on the rights of juries* (1792), and he long meditated the compilation of a digest of the statutes. His scientific theories, his mechanical experiments, and his studies in music absorbed all his thoughts, and for them he neglected his wife and his children. His youngest daughter, Lady Lucy Rachel Stanhope, eloped with Mr. Thomas Taylor of Sevenoaks, the family apothecary, and her father refused to be reconciled to her, an inconsistency in a republican which subjected him to a caricature from Gillray. Lady Hester Stanhope abandoned her home and went to live with her mother's relations. Lord Stanhope's high qualities were marred by an impracticable disposition.

STANHOPE, LADY HESTER LUCY (1776–1839), the oldest child of the third Earl Stanhope (noticed above), by his first wife Lady Hester Pitt, eldest daughter of the first earl of Chatham, lived for the earlier part of her life amid the surroundings of a noble mansion, or in close communion with her uncle William Pitt, the most prominent minister of his age, and on his early death withdrew whilst still young to brood over the past in the solitudes of Pales tone. She was born on 12th March 1776, and dwelt at her father's seat of Chivening in Kent until early in 1800, when his excitable and wayward disposition drove her to her grandmother's house at Burton Pynsent. A year or

two later she travelled abroad, but her cravings after distinction were not satisfied until she became the chief of her uncle's household in August 1803. She sat at the head of his table and assisted in welcoming his guests, gracing the board with her stately beauty and enlivening the company by her quickness and keenness of conversation. Although her brightness of style cheered the declining days of Pitt and amused most of his political friends, her satirical remarks sometimes created enemies when more consideration for the feelings of her associates would have converted them into friends. Lady Hester Stanhope possessed great business talents, and when Pitt was out of office she acted as his private secretary. She was with him in his dying illness, and some of his last thoughts were concerned with her future, but any anxiety which might have arisen in her mind on this point was dispelled through the grant by a nation grateful for her uncle's qualities of a pension of £1200 a year, dating from 30th January 1806, which Lady Hester Stanhope enjoyed for the rest of her days. On her uncle's death she lived in Montague Square, London, but life in London without the interest caused by associating with the principal politicians of the Tory party proved irksome to her, and she sought relief from lassitude in the fastnesses of Wales. Whilst she remained on English soil happiness found no place in her heart, and her native land was finally abandoned for the East in February 1810. After many wanderings she settled on Mount Lebanon, and from this solitary position she wielded an almost absolute authority over the surrounding districts. Her control over the natives was sufficiently commanding to induce Ibrahim Pasha, when about to invade Syria in 1832, to solicit her neutrality, and this supremacy was maintained by her commanding character and by the belief that she possessed the gift of divination. Her cherished companion Miss Williams, and her trusted physician Dr Charles Lewis Meryon, dwelt with her for some time, but the former died in 1828, and the latter was not with Lady Hester when she died. In this lonely residence, the villa of Djoun, 8 miles from Sidon, in a house "hemmed in by arid mountains," and with the troubles of a household of twenty-three servants, unregulated by a single English attendant or friend and only waiting for her death to plunder the house, Lady Hester Stanhope's strength slowly wasted away, and at last she died on 23d June 1839, aged sixty-three. The disappointments of her life, and the necessity of overawing her servants as well as the chiefs who surrounded Djoun, had intensified a temper naturally imperious. In appearance as in voice she resembled her grandfather, the first Lord Chatham, and like him she domineered over the circle, large or small, in which she was placed.

Some years after her death there appeared three volumes of *Memoirs of the Lady Hester Stanhope as related by herself in Conversations with her Physician* (i.e., Dr Meryon), 1845, and these were followed in the succeeding year by three volumes of *Travels of Lady Hester Stanhope, forming the Completion of her Memoirs narrated by her Physician*. They presented a lively picture of this strange woman's life and character, and contained many anecdotes of Pitt and his colleagues in political life for a quarter of a century before his death.

STANHOPE, PHILIP DORMER, fourth earl of Chesterfield. See CHESTERFIELD.

STANISLAU (Pol. *Stanislavoff*), the chief town in the district of the same name in Galicia, Austria, on the Albrecht and Lemberg Czernowitz railways, in 49° 4' N lat., 24° 30' E. long., has two real-schools, a gymnasium, and large ironworks. It has also a good trade in corn. The population (1885) numbers 18,626.

STANISLAUS (1677–1766), king of Poland. Stanislaw Leszczyński or Leszinski was born at Lemberg on October

20, 1677. His father, Raphael Leszczyński, was a Polish nobleman, distinguished by his rank and the important offices which he held, but still more by his personal qualities. Stanislaus, after visiting the courts of Vienna, Paris, and Rome, was raised to the dignity of vojvode of Posen, and in 1704 was sent as ambassador by the assembly of Warsaw to Charles XII of Sweden, who had just declared the deposition of the recently elected Augustus II. The king was so greatly taken with the ambassador that he recommended him to the diet as a suitable candidate for the vacant throne, the election accordingly followed on 12th July 1704, but the coronation of Stanislaus and his wife Catharina Opalinska did not take place until 4th October of the following year (compare POLAND, vol. xix p. 297). After the reverse of Poltava in 1709 Augustus returned to Poland, and, assisted by the Russians, compelled Stanislaus to leave the country. The next five years saw him leading a wandering and somewhat adventurous life in Europe, one of his objects being to procure a favourable peace for Charles (compare CHARLES XII). He then settled on Charles's estate at Zweibrücken, and after Charles's death in 1718 had a residence assigned to him by the French court at Weissenburg in Alsace. In 1725 his daughter Maria became the wife of Louis XV of France. On the death of Augustus in 1733 Stanislaus once more returned to Poland, where a majority declared for him, but his competitor, the young elector of Saxony, had the advantage of the support of the emperor Charles VI, and also of the empress of Russia. Dantzig, to which Stanislaus had retired, was quickly taken by the Russians and the Saxons, and with great difficulty the unfortunate prince succeeded in making good his escape in disguise, after hearing that the Russians had set a price on his head. In 1736, when peace was concluded between the emperor and France, it was agreed that Stanislaus should abdicate the throne, but that he should be acknowledged king of Poland and grand-duke of Lithuania, and continue to bear these titles during life, and further, that he should be put in peaceable possession of the duchies of Lorraine and Bar, but that immediately after his death those duchies should be united for ever to the crown of France. The remaining years of his life were prosperous and happy. He died at Lunéville on February 23, 1766, in consequence of injuries received from his nightdress accidentally taking fire.

Stanislaus, who was a patron of the arts and sciences, wrote several works in politics and philosophy, which were collected and published at Paris in 1763, in 2 vols. 8vo, under the title *Œuvres du Philosophe Bienfaisant. The Œuvres Choieses de Stanislas, Roi de Pologne, Duc de Lorraine et de Bar*, with an historical notice by Madame de Saint Ouen, were published in an 8vo volume at Paris in 1825.

STANISLAUS AUGUSTUS, the last king of Poland, was born at Wolczyn in Lithuania in 1732 and died at St Petersburg in 1798. See PONIATOWSKI, vol. xix p. 453, and POLAND, vol. xix pp. 297–8.

STANLEY, ARTHUR PENRHYN (1815–1881), dean of Westminster from 1863, was born at Alderley in Cheshire on December 13, 1815. His father, the Rev. E. Stanley, rector of Alderley, bishop of Norwich from 1837 to 1849, was the younger brother of Sir John Stanley of Alderley Park, seventh baronet, who in 1839 was created Baron Stanley of Alderley, and was the representative of a branch of the same family as that of the earls of Derby. His mother, Catherine Stanley, was the daughter of the Rev. Oswald Leycester, rector of Stoke-on-Tern. Both parents were persons of remarkable force and individuality of character. The influence of each is to be traced in the career of their son. It was his father's prayer as bishop of Norwich "that he might be an instrument in God's providence of extending more enlarged and more Christian views among the clergy, and thus the means of disseminating a wider

and more comprehensive spirit of Christianity throughout the land." Of his mother her son not only spoke, after her death in 1862, as "the guardian genius" that "had nursed his very mind and heart," but described her as "gifted with a spiritual insight which belonged to that larger sphere of religion which is above and beyond the passing controversies of the day." Arthur was their third child. His elder brother, Owen, died in 1850 at Sydney, after concluding, as commander of the "Rattlesnake" frigate, the survey of the Coral Sea. His sister Mary, well known for her work in the hospitals at Scutari and among the poor in London, died in 1880. Arthur was a child of highly sensitive organization and precocious intellectual activity. His boyish letters, journals, and poems were singularly like in their characteristic points to his later writings. But his extreme shyness and silence gave no promise of the social gifts which afterwards added so largely to his influence. At the age of fourteen his health, at one time alarmingly delicate, so far improved as to warrant his parents in sending him to Rugby, where Dr Arnold had been recently appointed head master. He remained at Rugby from 1829 to 1834, and of all Arnold's pupils may be said to have been the one who most fully responded to the influence of his master's teaching and character. In 1834 he became an undergraduate of Balliol College, Oxford, having obtained a scholarship in the previous year. Among his tutors at Balliol was Mr Tait, afterwards archbishop of Canterbury, and among his junior fellow scholars Benjamin Jowett, afterwards professor of Greek and master of Balliol. Arthur Stanley, after obtaining the Ireland scholarship and Newdigate prize for a remarkable English poem (on the Gipsies), was placed in the first class in 1837. In 1839, after a period of residence and study at Oxford, he was elected fellow of University College, and in the same year was admitted to holy orders. In 1840 he left England for a prolonged tour in Greece and Italy, and on his return settled at Oxford, where he resided from October 1841 for the next ten years, being actively engaged during term time as tutor of his college. He very shortly became an influential element in university life. His personal relations to his pupils were of a singularly close and affectionate nature, and the charm of his social gifts and genial character won him friends on all sides. His literary reputation was early established by the profound impression made by his *Life of Arnold*, whose sudden death had occurred in 1842, and whose biography, published in 1844, at once secured for its young author a high place among English writers. In 1845 he was appointed select preacher, and published in 1847 a volume of *Sermons and Essays on the Apostolic Age*, which not only laid the foundation of his fame as a preacher, but also marked his future position as a theologian. In university politics, which at that time were mainly the form of theological controversy, he from the first took the place which he always retained of an uncompromising advocate of comprehension and toleration. As an undergraduate he had entirely sympathized with Dr Arnold in resenting the agitation led by, but not confined to, the High Church party in 1836 against the appointment of Dr Hampden to the regius professorship of divinity. As a young M.A., during the long continued agitation which followed the publication in 1841 of Tract No 90, and which ended in the withdrawal of the present Cardinal Newman from the English Church, he used all his influence to protect from formal condemnation the leaders and tenets of the "Tractarian" party. In 1847 he did his utmost to resist the movement set on foot at Oxford against Dr Hampden's appointment to the bishopric of Hereford. Finally, in 1850, in an article published in the *Edinburgh Review* in defence of the "Gerham judgment," which had secured

the position in the English Church of the Evangelical clergy, he asserted two principles which he maintained to the end of his life,—first, "that the so-called supremacy of the crown in religious matters was in reality nothing else than the supremacy of law," and, secondly, "that the Church of England, by the very condition of its being, was not High, or Low, but Broad, and had always included, and been meant to include, opposite and contradictory opinions on points even more important than those at present under discussion."

It was not only in theological but in academical matters that his sympathies were on the liberal side. Though on many points of essentially conservative tendencies, he was greatly interested in university reform, and towards the end of his residence at Oxford acted as secretary to the royal commission appointed in 1850 to report on and to suggest improvements in the administrative and educational system of the university. Of the important changes in both these respects which, in the face of much opposition at the university, were carried out in due time under the sanction of parliament by an executive commission, Stanley, who took the principal share in drafting the report printed in 1852, was a strenuous advocate. These changes included the transference of the initiative in university legislation from the sole authority of the heads of houses to an elected and representative body, the opening of college fellowships and scholarships to competition by the removal of local and other restrictions, the non-enforcement at matriculation of subscription to the Thirty-nine Articles, and various steps taken to increase the usefulness and influence of the professoriate.

Before the report was issued, Stanley, who had lost his father in 1849, and both his brothers, Captain Stanley mentioned above, and Charles, secretary to the governor of Van Diemen's Land, within a few months of the same date, was appointed to a canonry in Canterbury cathedral. He held the office from 1851 till his return to Oxford. During his residence at Canterbury he published his *Memoir of his father Bishop Stanley* (1851), and completed his *Commentary on the Epistles to the Corinthians* (1855). In the winter and spring of 1852-53 he made the tour in Egypt and the Holy Land, the result of which was his well known volume on *Sinai and Palestine*, first published in 1856. In 1857 he travelled in Russia, and collected much of the materials for his subsequent *Lectures on the Greek Church*, published in 1861. His *Memoirs of Canterbury*, published in 1855, displayed the full maturity of his power of dealing with the events, scenes, and characters of past history which had marked him from childhood. Towards the close of the same period he accepted the office of examining chaplain to Dr Tait, his former tutor at Balliol and afterwards successor to Arnold at Rugby, on his transference from the deanery of Carlisle to the see of London.

At the close of 1856 Stanley was appointed by the crown to the professorship of ecclesiastical history, a post which, with the canonry at Christ Church attached to the office, he held till 1863. In the first of three inaugural lectures the new professor announced his intention of beginning his treatment of the subject with "the first dawn of the history of the church," the call of Abraham, and the first two volumes of his *History of the Jewish Church*, published in 1863 and 1865, consist of the substance of lectures delivered by him in his capacity as professor. In 1861 he published the volume on the Greek Church already referred to. His second residence at Oxford was marked by the same power of winning personal influence which had distinguished him as a college tutor, and by the efforts which he made, in his wider sphere as professor, to bring together in social intercourse

the leaders of the divergent and hostile parties between which the residents at the university were mainly divided.

Much, however, of his time and efforts was given to religious controversy. From 1860 to 1864 academical and clerical circles were agitated by the storm which followed the publication of *Essays and Reviews*, a volume to which two of his most valued friends—Benjamin Jowett and Mr Temple, the former professor of Greek at Oxford, the latter head master of Rugby and afterwards bishop in succession of Exeter and London—had been contributors. For the exceedingly prominent part taken by Stanley in this exciting controversy, the reader is referred to the second and third of his *Essays on Church and State*, collected and published in 1870. The result of his action was greatly to alienate the leaders of the High Church party, who had joined a large portion of the clergy in their efforts to procure the formal condemnation of the views advanced in *Essays and Reviews*. In this and other questions, such as in the growing controversy on the position of Prof Maurice at King's College, Cambridge, and on that caused by Bishop Colenso's work on the Pentateuch, he had taken up a position which brought him into conflict with a large portion of the religious public. It should be added that in the last year of his professoriate (1863) he had published a *Letter to the Bishop of London*, strongly advocating a large relaxation of the terms of clerical subscription to the Thirty-nine Articles and Prayer book. An important Act amending the Act of Uniformity, and carrying out in some degree Stanley's proposals, was passed in the year 1865.

In the spring of 1862 Stanley, at the queen's desire, had accompanied the prince of Wales on a tour in Egypt and the Holy Land. During his absence he lost his mother, the heaviest domestic bereavement that had yet befallen him. His sense of his debt towards her has been already indicated. It stands recorded in his volume of *Memorials of Edward and Catherine Stanley*.

Towards the close of the following year he was appointed by the crown to the deanery of Westminster, in succession to Dean Trench, raised to the see of Dublin. In December he married Lady Augusta Bruce, sister of Lord Elgin, then governor general of India, herself one of the queen's most trusted friends. In January 1864 he entered on the duties of his new post.

His tenure of the deanery of Westminster was memorable in many ways. He recognized from the first two important disqualifications,—his indifference to music and his slight knowledge of architecture. On both these subjects he availed himself largely of the aid of others, and threw himself with characteristic energy and entire success into the task of rescuing from neglect, preserving from decay, and commending to the interest of all classes of his countrymen the treasure of historic monuments in which the abbey is so rich. No visitor can pass through the building, now so often thronged with crowds of the working classes, the mere possibility of attracting whom was spoken of before a royal commission so lately as 1841 as quite chimerical, without recognizing the successful result of his indefatigable labours. The monument to the brothers Wesley, the inscription on the gravestone of Livingstone, and the restored altar in her husband's chantry in which he placed the neglected remains of Catherine of Valois, the queen of Henry V., may be named among the innumerable and ubiquitous records of his wide sympathy and historic ardour. Within three years of his appointment he published his *Memorials of Westminster Abbey*, a work which, although not free from occasional inaccuracies, is a mine of information conveyed in the most picturesque and impressive form. He was a constant preacher, and gave a great impulse to the practice already begun of inviting distinguished preachers to the abbey

pulpit, especially to the evening services in the nave, which had been established under his predecessor. It is to him that is largely due the vast increase in the number not of visitors only but of worshippers in the abbey. He began the practice, since continued by others of the abbey clergy, of devoting his Saturday afternoons to conducting parties of working men round the abbey and collegiate buildings. His social and personal influence, already unique of its kind, was enormously increased by his removal to London. His circle of friends was constantly widening, and extended from the queen and royal family to the working men of London and elsewhere, some of whom he inspired with a singular devotion. It included men of every denomination, every class, every part of the United Kingdom, and almost of every nation. He was untiring in literary work, and, though this consisted very largely of occasional papers, lectures, articles in reviews, addresses, and sermons, it included a third volume of his *History of the Jewish Church*, a volume on the *Church of Scotland*, another of *Addresses and Sermons* preached in America, and an exceedingly important volume, completed within a few months of his death, on *Christian Institutions*.

He was continually engaged in theological controversy, and, if his advocacy of all efforts to promote the social, moral, and religious amelioration of the poorer classes and his chivalrous courage in defending those whom he held to be unjustly denounced won him the warm admiration of many of his countrymen, he undoubtedly incurred much and growing odium in influential circles. Among the causes of offence might be enumerated, not only his vigorous defence of one from whom he greatly differed, Bishop Colenso, but his invitation to the holy communion of all the revisers of the translation of the Bible, including a Unitarian among other Nonconformists, as well as the whole tone and teaching of almost every page of his publications. Still stronger was the feeling caused by his efforts to make the recital of the Athanasian Creed optional instead of imperative in the *English Church*.

In 1874 he spent part of the winter in Russia, whither he and Lady Augusta had gone to take part in the marriage of the duke of Edinburgh. In the spring of 1876, after a long and lingering illness, he lost his wife, the zealous partner of all his social and charitable efforts, and the constant cheerer and sympathizer in his many labours and conflicts. It was a terrible blow, and one from which he never entirely recovered. But in 1878 he was deeply interested by a tour in America, and in the following autumn visited for the last time, with his sister, Mary Stanley, who died before the close of the same year, northern Italy and Venice.

In the spring of 1881 he preached funeral sermons in the abbey on Mr Carlyle and Lord Beaconsfield, winding up with the latter a series of *Sermons preached on Public Occasions*, mainly on the death or funeral of eminent Englishmen, which form a volume singularly characteristic of his special gifts. He saw also the completion of the latest of his volumes, that already mentioned on *Christian Institutions*, and was in the course of the summer correcting for the press a paper on the *Westminster Confession*, and preaching in the abbey a course of *Saturday Lectures on the Beatitudes*. On July 10 he was attacked by a sudden illness, which in a few days assumed a more alarming character, and ended fatally on the 18th. The sensation caused by his death was profound and widespread. He was buried in Henry VII's chapel, in the same grave as his wife. His pall bearers comprised representatives of literature, of science, of both Houses of Parliament, of theology, Anglican and Nonconformist, and of the universities of Oxford and Cambridge. The recumbent monument placed upon the spot, and the windows in the

chapter house of the abbey, one of them a gift from the queen, were a tribute to his memory from friends of every class in England and America.

The influence of Dean Stanley was no doubt largely due to his marvellous social gifts. His affectionate nature, his quick and ready sympathy, his keen interest in almost every field of knowledge, his own mental resources, drawn from incessant reading and enriched by travel, observation, and conversation, his familiarity with the persons, places, events, and scenes of history, his tenacious yet discriminating memory, his vivacity and humour, the very charm of his countenance and manner, the delicately sensitive face, "the eye now beaming with sympathy, now twinkling with humour," acted like a spell in winning friends and even in convincing opponents. The courage and fearlessness with which he was always ready to uphold the cause of those whom he held to be unjustly attacked by a powerful or dominant majority was duly appreciated by his countrymen. It may probably be said that no one in the present century was so endeared to so large a circle of personal friends in all parts of the civilized world. His writings also, apart from their controversial aspect, were of a singularly attractive kind. His *Life of Arnold*, his *Sinai and Palestine*, his *Lectures on the Jewish Church*, his *Memoirs of Canterbury* and of Westminster Abbey, would alone have made him one of the most delightful and popular of English authors. His sermons, always interesting and attractive, were at times singularly eloquent and impressive. His occasional hymns and short poems, full of grace and force, and occasionally of a profound pathos, were fully worthy of his literary position. Throughout all that he ever wrote there is an individuality and a characteristic flavour which is saved from mannerism by an inexhaustible freshness of view and a marvellous fertility of illustration. His power of painting the scenes, events, and persons of past history, "the picturesque sensibility," to use a phrase applied to him by Lord Beaconsfield, with which he at once fastened on the main features of an historic building or a famous locality, amounted to genius, they were as marked at the close of his life as in the earliest of his schoolboy letters. They won him readers of every class.

But it would be impossible to speak even briefly of his literary position by itself. To write his life in full would be to give a sketch of English ecclesiastical history for a long generation. Though he resolutely stood aloof from all connexion with party, it is impossible not to recognize even in his least controversial writings the position which he held as, in the eyes of the greatest portion of his countrymen, the leading liberal theologian of his time in England. Throughout his writings in prose or poetry, on almost every subject which he touched, we see the impress, not only of his distinctive genius and of his extraordinary gifts, but also of his special views, aims, and aspirations. It may be well to describe these as nearly as possible in his own words. He looked on the age in which he lived as one of mingled hope and gloom, as a period of transition, to be followed either by an "eclipse of faith"—a "winter of unbelief"—or by a "revival of Christianity in a wider aspect," a "catholic, comprehensive, all-embracing Christianity" that "might yet overcome the world." He believed, and was never tired of asserting his belief, "that the Christian church had not yet presented its hitherto its most perfect aspect to the world," that "the belief of each successive age of Christendom had as a matter of fact varied enormously from the belief of its predecessor," that "all confessions and similar documents are, if taken as final expressions of absolute truth, misleading," that each "successive form of theology is but the approximation to the truth, not the whole truth itself," that it was "the glory of the church to be always advancing to perfection," and that "there still remained, behind all the controversies of the past, a higher Christianity which neither assailants nor defenders had fully exhausted."

Already even in his early *Sermons on the Apostolic Age*, as in *Sinai and Palestine*, as in the volumes on the *Jewish Church*, "one increasing purpose" may be recognized. I everywhere see the sustained effort to "bring the events, places, and characters of sacred history within the domain of actual observation and history," and to rescue them from "the conventional haze in which they had been veiled by a misplaced reverence." "The first duty of a modern theologian," he held to be "to study the Bible, not for the sake of making or defending systems out of it, but for the sake of discovering what it actually contains." "In a faithful study of that virgin mine, the yet insufficiently explored records of the Old and New Testament, lay," he held, "the best hope of the church of Christ," and another and a different estimate "of the points on which Scripture lays its most emphatic stress." To this study he looked for the best hope of such a progressive development of Christian theology as should avert the danger arising from "the apparently increasing divergence between the intelligence and the faith of our time," and should enable the church to deal wisely with new questions which ancient theology had for the most part not even considered. On the direction which this development of theology should assume the last word had not, he knew,

been spoken, but he enforced the duty "of placing in the background whatever was accidental, temporary, or secondary, and of bringing into due prominence what was primary and essential." In the former group Stanley would, without doubt or hesitation, have placed all questions connected with Liturgical or Presbyterian orders, or that deal only with the outward forms or ceremonies of religion, or with the authorship or age of the books of the Old Testament. Even to the question of miraculous and external evidence he would have been inclined to assign a secondary place, as well as to the most elaborate statements of Christian doctrine.

The foremost and highest place, that of the "essential and supernatural" elements of religion, he would have reserved for its moral and spiritual truths, "its chief evidence and chief essence," "the truths to be drawn from the teaching and from the life of Christ," in whose character he did not hesitate to recognize "the greatest of all miracles." On a large development of Christian teaching in this direction he based all his hopes alike of the progress of the world and of the restitution to Christian theology—"as something greater and vaster than the theology of each particular church or age," "as comprehending all the wholesome elements of thought at work in the world"—of "its natural ascendancy over the minds of educated men."

With such views it was not to be wondered at that, from first to last, he never lost an opportunity of supporting a policy of width, toleration, and comprehension in the Church of England. The view which he took in his earliest directly controversial work, his *Essay on the German Judgment* (1850), as regards both the protection offered by the law to the clergy against "the inquisition of arbitrary prelates and of tumultuous synods," and "on the designedly mixed and comprehensive character of the English formularies and English Church," has already been fully indicated. The same spirit and the same aims guided his line of conduct in other controversies, such as in that on the *Essays and Lectures*, on the ritualistic movement, on the question of subscription, on the successive attacks made on men so wholly different from each other as Prof. Maurice, whose influence on the mind of his generation has yet to be fully estimated, and Bishop Coleman, and in his vain but earnest advocacy of the optional instead of the compulsory use of the Athanasian Creed. So again he was always eager to insist on the essential points of union between various denominations of Christians, however apparently divided or estranged, and to recognize the special services conferred on the world, not only by the Eastern, the Roman, the Lutheran, and the Reformed Churches, not only by the Presbyterian Churches of Scotland, but also by the Baptist and Congregational Churches of England and America, and by the community of Quakers. And, while in this respect he was keen almost to excess to note points of agreement, so in the very latest volume which he published one of his main aims was "to look the facts of history in the face" and to point out "the almost universal departure from primitive usage," "the transformation both of letter and spirit through which the greatest Christian ordinances had already passed," and "to fix the eye steadily on the germs of truth that were common to the different forms which the ordinances wore, the moral and spiritual realities for the sake of which alone (if Christianity be the universal religion) such forms exist." He was throughout his life an unflinching advocate of the connexion between church and state. By this he understood—(1) "the recognition and support on the part of the state of the religious expression of the faith of the community," and (2) "that this religious expression of the faith of the community on the most sacred and most vital of all its interests should be controlled and guided by the whole community through the supremacy of law." In the supremacy of the crown, i.e., of law, "over all causes and all persons, ecclesiastical as well as civil," so far from finding "galling chains" or "ignominious bondage," he welcomed it not only as being "the most powerful and intelligent organ of the whole community," but on two other grounds. First, he considered that supremacy more likely "to be truly wise and truly just and therefore truly Christian than the headship either of a bishop or of a synod of any clerical or sectional body," and, secondly, "as the best security for that gradual growth of religious forms and religious opinions, and for that free expression of individual belief, which is indispensable to any healthy development of religious life and religious truth." At the same time he was in favour of marking the creed of the church as wide as possible,—"not narrower than that which is even now the test of its membership, the Apostles' Creed,"—and of throwing down all barriers which could be wisely dispensed with to admission to its ministry. As an immediate step he even advocated as "an unmitigated good" "the admission under due restrictions of our nonconforming brethren of England, and our Presbyterian brethren of the Scottish Church," to preach in Anglican pulpits. To the last hour of his life he looked with dismay to the prospect of a combined assault by a triple alliance of the representatives "of the Puritans, of Voltaire, and of Laud" on "that rare combination which with all its shortcomings exhibits one of the noblest works which God's providence, through a long

course of years, has risen up in Europe," "on the most venerable growth of English history, the framework which has sheltered down to this time the freedom of the freest, the teaching of the most learned, and the reason of the most rational church in Christendom." He believed that the "excess of such an attack would result in throwing away the best opportunity which the world affords for the growth side by side of intellectual activity and religious earnestness," that to destroy it would be, as he said of the Established Church of Scotland, "to destroy, so far as human efforts can destroy, the special ideas of freedom, of growth, of comprehension which are inherent in the very existence of a national church," that its destruction would only produce "an enslaved clergy amidst an indifferent laity," and tend to degrade the Church of England from its historic position "to that of an illiterate sect, or a satellite of the Church of Rome."

With such views it was impossible that Stanley could have found much sympathy from either of the two great parties among the English clergy. Indeed it was impossible that any party, or any community, which placed the essence of Christianity in the careful guardianship of any circle of theological doctrines could feel in harmony with one who dwelt with such exceeding and growing emphasis on the secondary nature, not only of all that was ceremonial, but on much that was dogmatic, as compared with that which was spiritual and moral.

By the "Evangelical" section of the religious world the biographer of Arnold had been looked on from the first with more than suspicion. Later on, even the mode and form of his defence of their own side in the Gorham controversy, his avowed advocacy of a wide freedom of thought on many questions, especially those connected with Biblical criticism, his attitude towards such subjects as inspiration, justification, and future punishment, were more than distasteful. His loud acknowledgment of the debt owed by Christendom to German theology, "to the most laborious, truth-seeking, and conscientious of Continental nations," his persistent claims for a place within the Church of England for views that "went to the verge of Rome," the more than width—the universality—of his religious sympathies, his delight in placing, not Walter Scott only, or Tennyson, or the author of *Ecce Homo*, but Goethe, and Burns, and Matthew Arnold, and J. Stuart Mill in the ranks of religious teachers, were naturally repugnant to those who cared to read his works, and were not content to shrink in silent dismay from the warm sympathizer with Professor Maurice, the enthusiastic admirer of F. Robertson, and the apologist in turn of *Essays and Reviews* and of Bishop Colenso.

Against the feelings provoked by this aspect of his theological position, neither his acknowledged services to Biblical study, nor his profound and entire belief in the true key to the difficulties of the future being involved in the prosecution of that study, nor his sympathy with their own views as to the relation of the individual soul to God, nor his repeated, his almost daily assertions of the sacredness and value of the gospel history, or of the regenerative power of the Divine life and person of Christ as the "one Master worth living for, worth dying for," could avail much. Whatever the feelings of individuals, the organs of the party of whose once imperilled claim to remain within the fold of the Church of England he had been the staunchest upholder spoke of him from first to last with almost unqualified aversion. He was, or became in due time, even more obnoxious to at least the more advanced section of the High Church party. Nor was this to be wondered at. The differences between him and them were vital and fundamental, and, even where he defended their right—at one time repeatedly challenged—to maintain their distinctive views and observances in the Church of England, he rested their claim on grounds which would hardly win their approval or gratitude. The more clear sighted of their leaders felt that, if the points of ceremonial, of dress, posture, attitude, ritual, on which they laid exceeding stress, were treated by him with toleration, they were regarded with an indifference that verged upon contempt, as *infringements*, and that he delighted to trace their historical development, and to strip them of all that was essential, significant, or primitive. They felt even more strongly that in that which, to the leaders at least, gave their real interest and importance to all questions of vestments or observances, and even underlay some of the most important questions of religious doctrine,—the very existence of an order of priesthood as the divinely and exclusively commissioned channel of communication between God and man,—the rejection on the part of Stanley of their most cherished and central dogma was absolute and uncompromising. And the difference of view was vital. Much else in his writings might have been welcomed or condoned. His love for the past, his deep and full sympathy with much in the mediæval church, his warm admiration for many of its saints and heroes, his aversion to mere iconoclasm, his poetic and imaginative sensibility, had much to attract them. Even in his treatment of many important religious subjects it was often not so much his actual sentiments as the tendency—the more than tendency, the avowed aim—of all his writings to promote freedom of inquiry and of thought, rather

than submission to church authority, which provoked hostility. But on this question there was no room for compromise. That which they and he alike recognized as the fundamental tenet to which all their distinctive teaching pointed he spoke of as a belief "that they (the clergy) were the depositaries of mystical, supernatural, almost magical influence, independent of any moral or spiritual graces," and on this point he spoke with no doubtful voice. It was, he said, this belief in a "fixed, external, necessary medium on earth between the soul and God which, if he had rightly read the Psalms of David, the epistles of Paul and the gospel of Christ, true religion is always striving to dispense with," and "the more it can be dispensed with, the nearer and the higher is the communion of the human spirit with its Maker and its Redeemer." And this language (used in 1867) was in entire accordance with the manner in which in his latest volume (1881) he hinted at the possibility of "the growing materialism of the ecclesiastical sacerdotalism, so undermining the spiritual element of almost the only external ordinance of Christianity (the Eucharist), unquestionably the greatest religious ordinance in the world," "as even to endanger the ordinance itself." In addition to this fundamental divergence of view, it must be remembered that it was to this party, as the representatives of one "always forgetful in its gratitude and implacable in its vengeance," that he looked for the main danger to freedom of thought and width of comprehension in the future, and that he did not hesitate to remind them, even as he supported their claims to the largest possible interpretation of the Articles, that they "claimed a latitude themselves which they constantly refused to others." It will be easily understood therefore that whatever influence Stanley wielded in the church was wholly independent of either of the two great parties into which he found it mainly divided, above all of that which at the time of his death appeared to be every year growing in power and confidence.

What was the extent, what the permanent force of his own influence, is a question not easily answered at present. "Dean Stanley," said Dr. Story, "stood higher in the respect and affection of a larger and more varied circle of members of many churches than any ecclesiastic in the world." It is not easy to disengage his personal and social charm, the affection borne him by all who had even momentarily passed within the circle of his striking and attractive individuality, the warm feelings which much in his life, much in his writings, had called forth from multitudes who never saw him, from the more abiding impression made during his lifetime and after his death by the writings which he has left behind him. Yet if, setting aside one single name, that of Prof. Maurice, he be taken as the most prominent, the most fertile, the most gifted, and the most impressive exponent and defender of liberal theology, some estimate may be formed even now of the mark which he made upon his age. It would be easy to under-value the effect of the work which he did. It might seem at first sight as if his own gloomier anticipations had been fulfilled. He spoke from time to time of a danger of the age being overwhelmed, now by "a general return of forgotten superstitions," now "by a general chaos of incredulity," and of himself as "having perhaps done no more than make good a starting point for those who come after us, perhaps in the 20th or 21st century." He might have seemed to enter into the spirit of his father's words, "My only hope and consolation is that I am a pioneer for better days, and that the seed which I am, as far as can be, at sowing may bring forth fruit when I am gone to a better and more peaceful world." But such a view would be to a large extent superficial. If the success achieved by the cause of which Stanley was the main representative is carefully weighed, it will be found to be great in solid and direct results, far greater probably in those which are less easily summed up and tabulated. On the questions which he had most at heart, the real and careful and critical study of the sacred records, the progress made since he first lectured as a tutor at Oxford on the Old and New Testaments has been enormous. The large majority of the works published have been written more or less in the spirit in which he would have largely or entirely sympathized. It may be added that of these there are few which would not have encountered, if not fierce criticism, yet at least grave suspicion, some forty years ago. The combination of a reverent treatment of Holy Scripture with fearless inquiry into all questions connected with its criticism is a new birth in English literature. It is one in which he took a leading part, and in the defence of which he bore, sometimes in his own behalf, oftener in chivalrous defence of others, much of the brunt of the earlier and later contests. The impulse which he gave to the study alike of the Bible and church history was a great one. In each he may be recognized, not of course as the originator, but as the representative, of a new school of thought and of treatment, and those who are most familiar with his writings can hardly open a new book by any English theologian, hardly read a sermon of many preachers, above all on any portion of the Old Testament, in which they do not trace his immediate influence. He may be said in a very true sense to colour the writings of many of those who most differ from him. The subjects to which he looked as

the most essential of all—the universality of the Divine love, the supreme importance of the moral and spiritual elements of religion, the supremacy of conscience, the sense of the central citadel of Christianity as being contained in the character, the history, the spirit of its Divine Founder—have beyond doubt, if not yet taken fully the place which he claimed for them, yet impressed themselves more and more on the teaching and the preaching of every class of clergy in the church. They have lifted the teaching of those who most differed from him far above the level of a mechanical or merely ceremonial form of mediæval worship. The great cause too for which he strove so hard, that of comprehension and mutual toleration, the true “enlargement of Christ’s church,” has gained much from his efforts,—much in the present, and perhaps, in spite of some appearances to the contrary, more in the future. What ever storms of party strife may be in store for the church, active and energetic Christians of opposite parties no longer waste their energies in mutual attacks, but have learned to work together in Christian teaching and in works of Christian beneficence. His surviving friends may rejoice to remember that no one person had, for, it may be, many generations, done so much as Stanley to draw together in friendly and social intercourse the leaders of various religious parties and of different denominations of Christians.

Those who live, and feel that they live, in an age of transition cannot venture to prophesy the precise form and colour of the religious movement which will in due time succeed that which now seems to be the most prevalent and the most outwardly active. But they may be permitted to hold that its main features were described and anticipated, even if dwelt on with excessive emphasis, by Stanley,—to believe that the next phase of a Christian theology which shall regain a due ascendancy over the thought and intelligence of the civilized world will be embodied in some larger realization of “the one unchangeable element in Christianity,” of the witness borne by the teaching and life of Christ to the higher and spiritual nature and destinies of man and to the “principles of freedom, justice, toleration, beneficence, self-denial, universal sympathy, and fearless love of truth, in which all the hopes of a true and permanent development of Christian theology must take their stand.” None will have laboured more earnestly in this cause than Arthur Stanley. (G. G. B.)

STANTON, EDWIN M’MASTERS (1814–1869), American statesman, was born in Ohio, December 19, 1814, graduated at Kenyon College in 1833, and was admitted to the bar of his native State. Just at the end of Buchanan’s administration in 1860–61, Stanton was called upon to act as attorney-general. In 1862, after the inauguration of Lincoln, the new president, who had had great difficulties with his war office, placed Stanton at its head, where he was at home at last. His intense vigour, excellent organizing powers, and scrupulous honesty were the life of the Federal war department throughout the Civil War, and it may be worth while to note that, after living through boundless opportunities of peculation, he died, like most of the public servants of the United States, a poor man. In spite of his many services to the country, it was not always easy for his associates to get on with him comfortably, and his quarrels with President Johnson were especially bitter in 1867–68, ending in the impeachment of Johnson by the House of Representatives. On the acquittal of the president Stanton resigned, and resumed the practice of law. President Grant, in 1869, made him a justice of the supreme court, but his work during the war had worn him out, and he died December 24, 1869.

STARAYA RUSSA, a district town of Russia, in the government of Novgorod, 62 miles to the south of that city, on the river Polist, by means of which and Lake Ilmoï it is brought into easy steamer communication with St Petersburg. Some brine springs, of no great strength, on the eastern side of the town, were used as a source for the supply of salt as late as 1865, yielding about 50,000 cwt. annually, at present they are used only as mineral waters, having a great resemblance to those of Krouznach. Some thousands of visitors resort to them every summer, and owing to this circumstance Staraya Russa is better built and kept than any other town in Novgorod. The 13,100 inhabitants are supported chiefly by the summer-visitors. About 100 individuals in all employ themselves in brick-making, tanning, and sawing timber, and there

is a trade in rye, oats, and flax shipped to St Petersburg to the value of about £50,000 per annum.

The name of Staraya Russa occurs in the Russian annals as far back as 1167. It was one of the minor towns of the republic of Novgorod, and suffered continually in the wars for possession of the region between Russia, Lithuania, and Livonia. It was afterwards annexed to Moscow.

STARCH is an organized product of the vegetable kingdom, forming one of the most important and characteristic elements of plant life, and an abundantly stored reserve material for the discharge of vegetative functions. It originates within the living vegetable cell through the formative activity of chlorophyll under the influence of light, and is consequently an unfailing characteristic of all plants containing that body (compare PHYSIOLOGY, vol. xiv. p. 54). Starch found within leaves and other green parts of plants is assimilated and transformed with great rapidity, accumulations of it are carried as starch formers, and red deposited as starch in special reservoirs or portions of plants as the period of maturity approaches. In this way the body is found to gorgo the stems of certain palms—the sago, &c.—just before these plants begin to form their fruit, it is the principal constituent of the underground organs of biennial and perennial plants, tap roots, root-stocks, corms, bulbs, and tubers, and it is abundantly stored in many fruits and seeds, as in the cereals and pulses, in bananas, bread-fruit, &c. It occurs in minute granules varying in diameter from 1 to 100 and over 200 micromillimetres, and the granules from different sources have each a distinct microscopic character, their forms and size being, however, affected according as they are aggregated in clusters or individually formed (see vol. ii. p. 631, figs 3 to 6). Under the microscope these granules are seen to consist of a nucleus or hilum surrounded by layers arranged concentrically or excentrically, and the relations of hilum and layers are the most distinctive features of individual starches. Whether the hilum point bears to the granule the relation of a nucleus is a matter of dispute, the general opinion being that the grains are formed from without inwards, the centre being invariably the softest and most soluble portion, while the outer layers are most closely related to cellulose. Starch consists of a white or yellowish white glistening powder, which on being rubbed between the fingers emits a crackling sound. It is only slightly acted on by cold water, but under the influence of heat in water it swells up, forming according to the proportions of starch and water a clouded opalescent paste. Iodine acts on it in water by producing a brilliant blue coloration, this reaction forming a very delicate and characteristic test. Diastase and dilute boiling sulphuric acid convert starch into a form soluble in hot water, whence it passes into a series of easily soluble dextrins, and finally into the condition of the sugars, dextrose and maltose. In its chemical relations starch consists of an intimate mixture of two isomeric bodies,—granulose and starch cellulose,—or rather of a series of gradations from the one to the other, the starch cellulose being principally in the external layers, while the granulose is found in the central portions of the granules. Starch cellulose is a body intermediate between granulose and ordinary cellulose, from the latter it is distinguished by being reducible to soluble starch by boiling in water and by digesting in caustic alkali. Together, the substances consist of a combination of carbon with hydrogen and oxygen, the commonly received formula being $C_6H_{10}O_5 + 2H_2O$, but Nageli, Sachsse, and many other recent investigators show reason why the molecule should be regarded as consisting of $C_{30}H_{52}O_{31} + 12H_2O$.

As an economic product starch in its separate condition is a most important alimentary substance, the chief pure

food starches being ARROWROOT, SAGO, TAPIOCA (*qqv*), and corn flour, the starch of the MAIZE (*qv*). In its combined condition, in cereals, &c, starch is certainly the greatest and foremost of all the elements of nutrition (compare DIETETICS and NUTRITION). In its other industrial relations starch is used—(1) directly, as a thickening material in calico printing, for the dressing and finishing of many textiles, for laundry purposes, adhesive paste, and powder, and (2) indirectly, for the preparation of dextrin and British gum and starch sugar. Maize, wheat, and rice starch are principally employed for the direct applications, and for the dextrin and starch sugar manufacture potato starch is almost exclusively selected.

In the preparation of starch the object of the manufacturer is to burst the vegetable cell walls, to liberate the starch granules, and to free them from the other cell contents with which they are associated. When, as in the case of the potato, the associated cell contents, &c, are readily separated by solution and levigation the manufacture is exceedingly simple. Potato starch is prepared principally by carefully washing the potatoes and in a kind of rasping machine reducing them to a fine pulp, which is deposited in water as raw starch. The impurities of this starch—cellulose, albuminoids, fragments of potato, &c—are separated by washing it in fine sieves, through the meshes of which the pure starch alone passes. The sieves are variously formed, some revolving, others moving horizontally or in such manner as to keep the material in agitation. The starch is then received in tanks, in which it settles, and so separates from the soluble albuminoids and salts of the potatoes. The settling of the starch is much retarded by the dissolved albuminoids, and to hasten the separation small quantities either of alum or of sulphuric acid are employed. Alum coagulates the albumen and to that extent contaminates the starch, while the acid acts on the starch itself and is difficult of neutralization. After the starch has settled, the brown coloured supernatant liquor is drawn off and the starch again washed either in tanks or in a centrifugal machine. Finally it is dried by spreading it in layers over porous bricks (a process not required in the case of starch washed in a centrifugal machine) and by exposure to the air, after which it still retains a large proportion of water, but is in a condition for making dextrin or starch sugar. For further drying it is ground to a rough powder, and dried thoroughly in a hot chamber, then reduced to a powder and sifted. A method of reducing potatoes to a pulp by slicing and heaping them up till fermentation takes place is said to give a large yield of starch, but it is not much practised.

In dealing with the starches of the cereals, there is greater difficulty, owing to the presence of gluten, which with water forms a tough elastic body difficult of solution and removal. The difficulty is experienced in greatest measure in dealing with wheat, which contains a large proportion of gluten. Wheat starch is separated in two different ways—(1) the fermentation method, which is the original process, and (2) by mechanical means without preliminary fermentation. In the fermentation process whole wheat or wheaten meal is softened and swollen by soaking in water. Wheat grains are, in this condition, ground, and the pulp, mixed to a thickish fluid with water, is placed in tanks, where it ferments, developing acetic and volatile acids which dissolve the gummy constituents of the wheat, with part of the gluten, and render the whole less tenacious. After full fermentation, the period of which varies with the weather and the process employed, the starch is separated in a washing drum. It is subsequently washed with water, which dissolves out the gluten, the starch settling in two layers,—one comparatively pure, the other mixed with gluten and some branny particles. These layers are separated, the second undergoing further washing to remove the gluten, &c., and the remaining operations are analogous to those employed in the preparation of potato starch. By the mechanical process wheat flour is kneaded into a stiff paste, which, after resting an hour or two, is washed over a fine sieve so long as the water remains off continue, milky, whereby the starch is liberated and the greater part of the gluten retained as a gluey elastic mass in the sieve. The starch is subsequently purified by fermentation, washing, and treatment in centrifugal machines. The gluten thus prepared is a useful food for diabetic patients, and is made with flour into artificial macaroni and pastes, besides being valuable for other industrial purposes.

Maize starch is obtained by analogous processes, but, the proportion of gluten in the grain being smaller, and less tenacious in its nature the operations, whether chemical or mechanical, present fewer difficulties. Under one method the separation of maize starch is facilitated by steeping, swelling, and softening the grain in a weak solution of caustic soda, and favourable results are also obtained by a process in which the pulp from the crushing mill is treated with water acidulated with sulphurous acid.

In the preparation of rice starch a weak solution of caustic soda is also employed for softening and swelling the grain. It is then washed with pure water, dried, ground, and sifted, and again treated with alkaline water, by which the whole of the nitrogenous constituents are taken up in soluble form. An acid process for obtaining rice starch is also employed, under which the grain, swollen and ground, is treated repeatedly with a solution of hydrochloric acid, which also dissolves away the non-starchy constituents of the grain. The laundry starches now in use are principally made from rice and from pulse. (J PA)

STAR-CHAMBER, the name given in the 15th, 16th, and 17th centuries to an English high court of justice, consisting of the members of the ordinary council, or of the privy council only, with the addition of certain judges, and exercising jurisdiction, mainly criminal, in certain cases. The origin and early history of the court are somewhat obscure. The Curia Regis of the 12th century, combining judicial, deliberative, and administrative functions, had thrown off several offshoots in the Court of King's Bench and other courts, but the crown never parted with the supreme jurisdiction whence the subsidiary courts had emanated. When in the 13th century the council became a regular and permanent body, practically distinct from the parliament of estates, this jurisdiction continued to be exercised by the king in council. As the ordinary law-courts became more systematic and important, the indefinite character of the conciliar jurisdiction gave rise to frequent complaints, and efforts, for the most part fruitless, were made by the parliaments of the 14th century (*eg.*, in 15 Edw II and 2 Edw III) to check it. The equitable jurisdiction of the chancellor, which grew up during the reign of Edward III, flowed from this supreme judicial power, like the common law-courts under Henry II, but without drying up the original source. It is in the reign of Edward III that we first hear of the "chancellor, treasurer, justices, and others" exercising jurisdiction in the "star chamber" or "chambre de estoiles" at Westminster. In Henry VI's reign one Danvers was acquitted of a certain charge by the king's council "in camera stellata." Hitherto such Acts of Parliament as had recognized this jurisdiction had done so only by way of limitation or prohibition, but in 1453, about the time when the distinction between the ordinary and the privy council first became apparent, an Act was passed by which the chancellor was empowered to enforce the attendance of all persons summoned by the privy seal before the king and his council in all cases not determinable by common law. At this time, then, the jurisdiction of the council was recognized as supplementary to that of the ordinary law courts. But the anarchy of the Wars of the Roses, and the decay of provincial justice owing to the influence of great barons and the turbulence of the lower classes, obliged parliament to entrust wider powers to the council. This was the object of the famous Act of 3 Hen VII, which was quoted by the lawyers of the Long Parliament as creating the court of star-chamber. This, however, as is shown above, it was far from doing. The Act of 3 Hen VII empowered a committee of the council, consisting of the chancellor, treasurer, privy seal, or any two of them, with the chief justices, or in their absence two other justices, a bishop, and a temporal lord, to act as a court of justice for enforcing the law in cases where it was thwarted by bribery, intimidation, or partiality. The jurisdiction thus entrusted to a committee of the council was not, therefore, like that granted in 1453, supplementary, but superseded the ordinary law-courts in cases where they were too weak to act. The Act simply supplied machinery for the exercise under special circumstances of that extraordinary penal jurisdiction which the council had never ceased to possess. This jurisdiction, Bacon tells us, was still further developed and organized by Wolsey. The court established by the

Act 3 Hen VII continued to exist for about fifty years, but disappeared towards the end of Henry VIII's reign. Its powers were not lost, but fell back to the general body of the council, and were among the most important of those exercised by the council sitting in the star-chamber. A court not unlike that created in 3 Hen VII was erected in 1510. The Act of 31 Hen VIII, which gave the king's proclamations the force of law, enacted that offenders against them might be punished by the usual officers of the council, together with some bishops and judges, "in the star chamber or elsewhere." These powers also came after a time, like those granted in 1188, to be exercised by the council at large instead of by certain members of it. It is clear, however,—and this was one of the chief complaints against the court,—that the jurisdiction which belonged by law or custom to the whole body of the king's council was usurped at this time by the inner body of advisers called the privy council, which had engrossed all the other functions of the larger body. Sir T. Smith (temp. Eliz.) tells us that juries misbehaving "were many times commanded to appear in the star-chamber or before the privy council for the matter." The uncertain composition of the court is well displayed by Coke, who says that the star chamber is or may be compounded of three several councils—(1) the lords and others of the privy council, (2) the judges of either bench and the barons of the exchequer, (3) the lords of parliament, who are not, however, standing judges of the court. Hudson (temp. Car I.), on the other hand, considers that all peers had a right of sitting in the court. The latter class had, however, certainly given up sitting in the 17th century. The jurisdiction of the court was equally vague, and, as Hudson says, it was impossible to define it without offending the supporters of the prerogative by a limitation of its powers, or the common lawyers by attributing to it an excessive latitude. In practice its jurisdiction was almost unlimited. It took notice of maintenance and livery, bribery or partiality of jurors, falsification of panels or of verdicts, riots and riots, murder, felony, forgery, perjury, fraud, libel and slander, offences against proclamations, duels, acts tending to treason, as well as of a few civil matters,—disputes as to land between great men or corporations, disputes between English and foreign merchants, testamentary cases, &c,—in fact, "all offences may be here examined and punished if the king will" (Hudson). Its procedure was not according to the common law, it dispensed with the encumbrance of a jury, it could proceed on mere rumour or examine witnesses, it could apply torture, it could inflict any penalty short of death. It was thus admirably calculated to be the support of order against anarchy or of despotism against individual and national liberty. During the Tudor period it appeared in the former light, under the Stuarts in the latter. It was abolished by the Long Parliament in 1641, and was never afterwards revived.¹

Hist. of England*, Guizot, *Engl. Verfassungsgeschichte*, Dicey, *The Privy Council* (Arnold Prize Essay). The pleadings in the star chamber are in the Record Office, the decrees appear to have been lost. (G. W. P.)

STARGARD, an ancient manufacturing town in eastern Pomerania, Prussia, is situated on the left bank of the navigable Ihna, 20 miles to the east of Stettin. Formerly a member of the Hansatic League, the town retains memorials of its early importance in the large church of

St Mary, built in the 14th and 15th centuries, the 16th-century town-house, and the well preserved walls with gateways and towers dating from the 14th century. The extensive new law courts and three large barracks are among the modern buildings. Stargard has a considerable market for cattle and horses, and carries on trade in grain, spirits, and raw produce. Its manufactures include cigars, tobacco, wadding, and stockings, and there are also iron foundries and linen and woollen factories in the town. The population in 1885 was 22,109 (in 1816 8706), of whom about 730 were Roman Catholics and about 560 Jews.

Stargard, mentioned as having been destroyed by the Poles in 1120, received town rights in 1229, and became the capital of eastern Pomerania. As a Hansatic town it enjoyed considerable commercial prosperity, but had also to undergo siege and capture in the Middle Ages and during the Thirty Years' War. In 1807 it was taken by Schill. The name Stargard (from the Slavonic Starograd or Starograd, meaning "old town") is common to several other towns in the north of Germany, of which the chief are Prussian Stargard, near Danzig, and Stargard in Mecklenburg.

STARLING (A S *Star*, *Stear*, and *Sterlyng*, Lat. *Sturnus*, Fr. *Étourneau*), a bird long time well known in most parts of England, and now, through the extension of its range within the present century, in the rest of Great Britain, as well as in Ireland, where, though not generally distributed, it is very numerous in some districts. It is about the size of a Thrush, and, though at a distance it appears to be black, when near at hand its plumage is seen to be brightly shot with purple, green, and steel-blue, most of the feathers when freshly grown being tipped with buff. These markings wear off in the course of the winter, and in the breeding season the bird is almost spotless. It is the *Sturnus vulgaris* of ornithologists.

To describe the habits of the Starling² within the limits here allotted is impossible. A more engaging and scarcely exists, for its familiarity during some months of the year gives opportunities for observing its ways that few others afford, while its varied song, its sprightly gestures, its glossy plumage, and, above all, its character as an insecticide—which last makes it the friend of the agriculturist and the grazier—render it an almost universal favourite. The worst that can be said of it is that it occasionally pilfers fruit, and, as it flocks to roost in autumn and winter among reed beds, does considerable damage by breaking down the stems.³ The congregations of Starlings are indeed very marvellous, and no less than the aerial evolutions of the flocks, chiefly before settling for the night, have attracted attention from early times, being mentioned by Pliny (*Hist. Naturalis*, v. 24) in the 1st century. The extraordinary precision with which the crowd, often numbering several hundreds, not to say thousands, of birds, wheels, closes, opens out, rises, and descends, as if the whole body were a single living thing—all these movements being executed without a note or cry being uttered—must be seen to be appreciated, and may be seen repeatedly with pleasure. For a resident, the Starling is rather a late breeder. The nest is commonly placed in the hole of a tree or of a building, and its preparation is the work of some little time. The eggs, from 4 to 7 in number, are of a very pale blue, often tinged with green. As the young grow they become very noisy, and their parents, in their assiduous attendance, hardly less so, thus occasionally making themselves disagreeable in a quiet neighbourhood. The Starling has a wide range over Europe and Asia, reaching India, but examples from Kashmir, Persia, and Armenia have been considered worthy of specific distinction, and the resident Starling of the countries bordering the Mediterranean is generally regarded as a good species, and called *S. unicolor* from its unspotted plumage.

Of the many forms allied to the genus *Sturnus*, some of which have perhaps been needlessly separated therefrom, those known as GRACKLES (vol. xi p. 26) have been already mentioned, and there is only room here to notice one other *Pastor*, containing a beautiful species *P. roseus*,

² They are dwell on at some length in Arrell's *British Birds*, ed. 4, vol. ii pp. 229-241.

³ A most ridiculous and unfounded charge has been, however, more than once brought against it—that of destroying the eggs of Skylarks. There is little real evidence of its sucking eggs, and much of its not doing so, while, to render the allegation still more absurd, it has been brought by a class of farmers who generally complain that Skylarks themselves are highly injurious.

¹ The name is probably derived from the stars with which the roof of the chamber was painted, but it has also been derived from a Hebrew word *shetar*, or *sh'etar*, a bond, on the supposition that the room was that in which the legal documents connected with the Jews were kept prior to their expulsion by Edward I.

the Rose-coloured Starling, which is not an unfrequent visitor to the British Islands. It is a bird of most irregular and erratic habits—a vast horde suddenly arriving at some place to which it may have hitherto been a stranger, and at once making a settlement there, leaving it wholly deserted as soon as the young are reared. This happened in the summer of 1875 at Villafranca, in the province of Verona, the castle of which was occupied in a single day by some 12,000 or 14,000 birds of this species, as has been graphically told by Sig de Betta (*Atti del R Ist Veneto*, ser 5, vol 11),¹ but similar instances have been before recorded,—as in Bulgaria in 1867, near Smyrna in 1856, and near Odessa in 1844, to mention only some of which particulars have been published.² (A N)

STARODUB, a district town of Russia, in the government of Tchernigoff, 116 miles to the north east of that town, on the marshy banks of a small tributary of the navigable Sudost. It is regularly built, with broad straight streets, the houses being surrounded by large gardens. Its 23,890 inhabitants—Little Russian descendants of former Cossacks with about 5000 Jews—support themselves chiefly by gardening and agriculture. Tanning is also carried on, and the trade in corn and hemp exported to Riga and St Petersburg has some importance.

Starodub at one time played a prominent part in the history of the Ukraine. As early as the 11th and 12th centuries it was a bone of contention between different Russian princes, who appreciated the value of its strategic position. The Mongols seem to have destroyed it, and its name does not reappear till the 14th century. During the 15th and 16th centuries the Russians and Lithuanians were continually disputing the possession of its fortress, and at the beginning of the 17th century it became a stronghold of Poland.

STARO-KONSTANTINOFF, a district town of Russia, in the government of Volhynia, situated 121 miles to the west-south-west of Zhitomir. It is an old-fashioned, poorly built town, dating from the 16th century, and is often mentioned in history in connexion with the rising of Cossacks under Bogdan Khmelnitzky. Owing to its excellent position close to the Austrian frontier and its railway communication with south west Russia, it has a very active trade in corn, cattle, and salt with Austria, Prussia, and Poland. Its population (17,980 in 1884, of whom two-thirds were Jews) is rapidly increasing.

STASSFURT, a town in the Prussian province of Saxony, and one of the chief seats of the German salt-producing industry, is situated on both sides of the Bode, 19 miles to the south-west of Magdeburg. Although saline springs are mentioned here as early as the 13th century, the first attempt to bore for salt was not made until 1839, while the systematic exploitation of the salt-beds, to which the town is indebted for its prosperity, dates only from 1856. The shafts reached deposits of salt at a depth of 850 feet, but the finer and purer layers lie more than 1100 feet below the surface. Besides the rock salt, which is excavated by blasting, the saline deposits of Stassfurt yield a considerable quantity of deliquescent salts and other saline products, which have encouraged the foundation of numerous chemical factories in the town and in the neighbouring village of Leopoldsdahl, which stands upon Anhalt territory. The formation of the Stassfurt salt beds and the composition of the rock-salt are described under SALT (vol XXI. pp 231, 232). The rock salt works are mainly Government property, while

¹ A partial translation of this paper is given in the *Zoologist* for 1878, pp 18-22.

² It is remarkable that on almost all of these occasions the locality pitched upon has been, either at the time or soon after, ravaged by locusts, which the birds greedily devour. Another fact worthy of attention is that they are often observed to affect trees or shrubs bearing rose coloured flowers, as *Nerium oleander* and *Robinia viscosa*, among the blossoms of which they themselves may easily escape notice, for their plumage is rose pink and black shot with blue.

the chemical factories are in private hands. About 2000 workmen are employed in the Stassfurt salt industry, and about 490,000 tons of raw salt are annually excavated. The population of the town, which contains one or two miscellaneous factories, was 16,457 in 1885.

STATE, GREAT OFFICERS OF. All the principal ministers of the British crown are popularly called the great officers of state. Under this designation are more or less accurately included the premier for the time being, the other members of the cabinet, and the leading functionaries of the court. But properly speaking the great offices of state are only nine in number, and it is to the holders of them alone that the description of "the great officers of state" strictly and distinctively applies. They are the lord high steward, the lord high chancellor, the lord high treasurer, the lord-president of the privy council, the lord-keeper of the privy seal, the lord great chamberlain, the lord high constable, the earl marshal, and the lord high admiral. Of these, three—the lord chancellor, the lord-president of the council, and the lord privy seal—are the first and second always and the third almost always cabinet ministers. The offices of two more—those of the lord treasurer and the high admiral—are now executed by commission, the chief of the lords commissioners, known severally as the first lord of the treasury and the first lord of the admiralty, being likewise members of the cabinet, while the first lord of the treasury is usually at the head of the Government. But, although it has become the rule for the treasury and the admiralty to be put in commission, there is nothing except usage of longer or shorter duration to prevent the crown from making a personal appointment to either of them, and the functions which formerly appertained to the lord treasurer and the high admiral are still regularly performed in the established course of the national administration. The four offices of the high steward, the great chamberlain, the high constable, and the earl marshal stand on a different footing, and can be regarded at the present day as little else than survivals from an earlier condition of society. They have practically ceased to have any relation to the ordinary routine of business in the country or of ceremonial in the palace, and the duties associated with them have either passed entirely into abeyance or are restricted within extremely narrow limits, save on certain occasions of exceptional pomp and solemnity. All of them were once hereditary, and, taking the three kingdoms together, they or their counterparts and equivalents continue to be held by right of inheritance in one or other of them even now. The prince of Wales is the hereditary great steward of Scotland, and the earl of Shrewsbury is the hereditary grand seneschal of Ireland. The great chamberlainship of England is held jointly by Lady Willoughby de Eresby and Lord Carrington on the one part and on the other part by the marquis of Cholmondeley. The hereditary high constable of Scotland is the earl of Erroll, and the hereditary earl marshal of England is the duke of Norfolk. It is of the great offices of the steward, the chamberlain, the constable, and the marshal that we shall at present speak, the rest of those we have mentioned being dealt with under their proper headings, or in the articles CABINET, MINISTRY, PRIVY COUNCIL, and ROYAL HOUSEHOLD.

The lord high steward of England ranks as the first of the great officers of state. His office is called out of stewardship by commission under the great seal only for coronations and for trials by the House of Lords. At the former he bears the crown of St Edward immediately before the sovereign in the procession to Westminster Abbey, and he presides at the latter on the arraignment of a peer or a peeress for treason or felony. From the reign of Richard II. to that of Henry VII. it was the duty of the

lord high steward to sit judicially in the court of claims to hear and determine all claims to render services of grand serjeanty to the king or queen at his or her coronation. Since the accession of the house of Tudor, however, this function has generally been discharged by a specially appointed commission, or a committee of the privy council. According to the tradition once current among lawyers and antiquaries, the steward of England was, under the Norman and Angevin kings, the second personage in the realm, the viceroy in the absence and the chief minister in the presence of the sovereign. Coke says, on the more than doubtful authority of an ancient manuscript, that his office was to superintend under the king and next after the king the whole kingdom and all the ministers of the law within the kingdom in time of both peace and war. But of this there is no satisfactory evidence. It is not improbable that the steward of England may for a short period after the Conquest have occupied a position analogous to that of the Saxon *herh-gerefa* or that of the Norman *seneschal*, or of the two in combination. But, as Stubbs points out, the chief minister and occasional viceroy, either alone or with others, of the Conqueror and his earlier successors was the person to whom the historians and the later constitutional writers give the name of *justiciarius* with or without the prefix "*summus*" or "*capitalis*." He adds that most likely the Norman *seneschalship* was the origin of the English *justiciarship*, that under Henry II the *seneschal* of Normandy receives the name of *justiciar*, and that it is only in the same reign that the office in England acquires the exclusive right to the definite name of "*summus*" or "*capitalis justitarius*" or "*justitarius totius Angliæ*." But whatever may have been his original condition the steward had been by that time at the latest eclipsed in his most important functions by the *justiciar*, and he makes, as Stubbs observes, in his official capacity no great figure in English history. By the reign of Henry II at any rate all connexion between the stewardship and the *justiciarship* had come to an end, and, while the second retained its authority unimpaired until its extinction, the first became a grand serjeanty, primarily annexed to the barony of Hinckley, it is said, and afterwards to the earldom of Leicester. On the attainder of Simon de Montfort the earldom and stewardship were forfeited, and both were granted by Edward I to his brother Edmund Plantagenet, earl of Lancaster, from whom they descended to the daughter and eventual heiress of Henry Plantagenet, duke of Lancaster. She was the first wife of John of Gaunt and the mother of Henry IV. On the accession of her son to the throne they became merged in the crown, from which period the stewardship has been revived only *hac vice* from time to time as occasion required. It is indeed to John of Gaunt that the pre-eminent position accorded to the office since the end of the 14th century is really due. It emerged from the comparative obscurity in which it had rested for nearly three hundred years as soon as he became the tenant of it by courtesy in right of his deceased wife. As far as any records show to the contrary he was the first steward of England who took part in the coronation of a king or queen, and he was certainly the first steward of England who sat in the court of claims or who presided at a trial by the House of Lords. It seems to have been by him also that the precedence of the stewardship before all the other great offices of state was secured, a restoration or augmentation of rank which is the more remarkable in that the steward of Scotland gave place to the chamberlain and the *seneschal* of Ireland gave place to the constable of the two kingdoms respectively. John of Gaunt may be regarded, in fact, as the creator of the lord high stewardship and all its privileges and prerogatives as they have existed from his days to our own.

The lord great chamberlain of England ranks as the sixth great officer of state. Whenever the sovereign attends the palace of Westminster the keys are delivered to him, and he is for the time in command of the building. At the opening or closing of the session of parliament by the sovereign in person he disposes of the sword of state to be carried by any peer he may select, and walks himself in the procession on the right of the sword of state, a little before it and next to the sovereign. He assists at the introduction of all peers into the House of Lords on their creation, and at the homage of all bishops after their consecration. At a coronation he receives the regalia from the dean and chapter of Westminster, and distributes them to the personages who are to bear them in the ceremony. On that day it is his duty to carry the sovereign in his shirt and wearing apparel before he rises and to serve him with water to wash his hands before and after dinner. The chamberlain was originally a financial officer, his work, Stubbs says, was rather that of auditor or accountant than that of treasurer, he held a more definite position in the household than most of the other great officers, "and in the judicial work of the country he was only less important than the *justiciar*." The office was hereditary in the Veres, earls of Oxford, from the reign of Henry I to the reign of Charles I, when it passed through an heiress to the Berties, Lords Willoughby de Eresby, and afterwards earls of Lindsey and dukes of Ancaster, and from the Berties it was transmitted through coheiresses to the present inheritors of the dignity. The Stuarts, dukes of Lennox, were hereditary great chamberlains of Scotland in the 16th and 17th centuries. The office on their extinction was granted by Charles II to James, duke of Monmouth and Buccleuch, on whose attainder it passed to Charles, duke of Richmond and Lennox, by whom it was surrendered to the crown in 1703.

The lord high constable of England ranks as the seventh of the great officers of state. His office is called out of abeyance for coronations alone, when it is his duty to assist in the reception of the regalia from the dean and chapter of Westminster, and during the coronation banquet to ride into Westminster Hall on the right hand of the champion. The constable was originally the commander of the royal armies and the master of the horse. He was also one of the judges of the court of chivalry or court of honour. The constablership was granted as a grand serjeanty with the earldom of Hereford by the empress Maud to Milo of Gloucester, and was carried by his heiress to the Bohuns, earls of Hereford and Essex. Through a coheiress of the Bohuns it descended to the Staffords, dukes of Buckingham, and on the attainder of Edward Stafford, third duke of Buckingham, in the reign of Henry VIII it became merged in the crown. The Laeys and Verduns were hereditary constables of Ireland from the 12th to the 14th century, and the Hays, earls of Erroll, have been hereditary constables of Scotland from early in the 14th century until the present time.

The earl marshal of England ranks as the eighth of the great officers of state. He is the head of the college of arms, and has the appointment of the kings-of-arms, heralds, and pursuivants at his discretion. He attends the sovereign in opening and closing the session of parliament, walking opposite to the lord great chamberlain on his or her right hand. It is his duty to make arrangements for the order of all state processions and ceremonies, especially for coronations and royal marriages and funerals. Like the lord high constable he rides into Westminster Hall with the champion after a coronation, taking his place on the left hand, and with the lord great chamberlain he assists at the introduction of all newly-created peers into the House of Lords. The marshal appears in the feudal

armies to have been in command of the cavalry under the constable, and to have in some measure superseded him as master of the horse in the royal palace. He exercised joint and co-ordinate jurisdiction with the constable in the court of Chivalry, and afterwards became the sole judge of that tribunal. The marshalship of England was made hereditary in the Clares and Marshals, earls of Pembroke, in the reign of Stephen or Henry II., and through a co-heiress passed to the Bigots, earls of Norfolk, and by Roger Bigot, fifth earl of Norfolk, it was surrendered with his other dignities to Edward I. It was granted by Edward II to his brother Thomas of Brotherton, earl of Norfolk, and, after it had been variously disposed of by Edward III, was by Richard II erected into an earldom and conferred on Thomas Mowbray, duke of Norfolk, who was the great-grandson and heir of Thomas of Brotherton. One of the co-heiresses of the Mowbrays was the mother of John Howard, duke of Norfolk, who was created earl marshal by Richard III. After several attainders and partial restorations in the reigns of the Tudors and the Stuarts, the earl marshalship was finally entailed by Charles II. on the male line of the Howards, with many specific remainders and limitations, under which settlement it has regularly descended to the present duke of Norfolk. The Clares and Marshals, earls of Pembroke, and the Lords Morley appear to have been hereditary marshals of Ireland from the invasion of the island until the end of the 15th century. The Keiths were Earls Marischal of Scotland from the institution of the office by James II in 1458 until the attainer of George, the tenth earl, in 1716.

On the subject of the great offices of state generally, see Stubbs, *Constitutional History*, ch. vi. Freeman, *Norman Conquest*, ch. xxi, Gneist, *Constitution of England*, ch. xvi, xxv, and lvi, also Gibbon, *Decline and Fall*, ch. lvi, and Bryce, *Holy Roman Empire*, ch. xiv.

STATEN ISLAND, an island of New York State, forming, with some adjacent islands, Richmond county, with a population of 38,991 in 1880, is situated about 5 miles south of New York city, from which it is separated by New York Bay, while the Narrows, commanded by Forts Wadsworth and Tompkins and a line of water-batteries, separate it from Long Island on the north east, Staten Island Sound from New Jersey on the west, and Newark Bay and the Kill van Kull from the same State on the north. It is of an irregular triangular shape, its greatest length being about 13 miles, its greatest breadth about 8, and the total area 58½ square miles. The surface is gently undulating, but a range of hills attaining 310 feet in height extends across the northern portion. Iron ore is found. The island contains many detached villa residences of persons in business in New York. On an artificial island off the east shore is the New York quarantine establishment, and Staten Island is the seat of the "Sailors' Snug Harbour," a retreat for superannuated seamen. Steam ferries ply half-hourly to New York, and on the island there is a railway line from Tompkinsville to Tottenville.

STATE PAPERS See **RECORDS, PUBLIC**

STATES OF THE CHURCH, or **PAPAL STATES** (Ital. *Stato della Chiesa*, *Stato Pontificio*, *Stato Romano*, *Stato Ecclesiastico*, Fr. *États de l'Église*, *Pontificat Souverain de Rome*, &c. Germ. *Kirchenstaat*, in ecclesiastical Latin often *Patrimonium Sancti Petri*), that portion of central Italy which, previous to the unification of the kingdom, was under the direct government of the see of Rome. The territory stood at the close as in the annexed table.

With the exception of Benevento, surrounded by the Neapolitan province of Principato Ultrioro, and the small state of Pontecorvo, enclosed within the Terra di Lavoro, the States of the Church formed a compact territory, bounded on the N W by the Lombardo-Venetian kingdom

on the N E by the Adriatic, on the S E. by the kingdom of Naples, on the S W by the Mediterranean, and on the W by the grand-duchy of Tuscany and the duchy of

Modena. On the Adriatic the coast extended 140 miles, from the mouth of the Tronto (Truentus) to the southern mouth of the Po, and on the Tyrrhenian Sea 130 miles, from 41° 20' to 42° 22' N lat. See vol. xiii Plate VI.

The divisions shown above were adopted on December 21, 1827, the legations being ruled by a cardinal and the delegations by a prelate. Previously the several districts formally recognized were Latium, the Marittima (or seaboard) and Campagna, the Patrimony of Saint Peter, the duchy of Castro, the Orvietano, the Sabina, Umbria, the Perugino, the March of Ancona, Romagna, the Bolognese, the Ferrarese, and the duchies of Benevento and of Pontecorvo.

The question of the origin of the territorial jurisdiction of the pope has been treated under **POPEDOM** (vol. xix p. 495). With the moral and ecclesiastical decay of the papacy in the 9th and 10th centuries much of its territorial authority slipped from its grasp, and by the middle of the 11th century its rule was not recognized beyond Rome and the immediate vicinity. By the treaty of Sutri (February 1111) Paschal II. was compelled by the emperor Henry V to surrender all the possessions and royalties of the church, but this treaty was soon afterwards repudiated, and by the will of Matilda, countess of Tuscany, the papal see was enabled to lay claim to new territories of great value. By the capitulation of Neuss (1201) Otto IV. recognized the papal authority over the whole tract from Radicofani in Tuscany to the pass of Ceperano on the Neapolitan frontier—the exarchate of Ravenna, the Pentapolis, the March of Ancona, the bishopric of Spoletto, Matilda's personal estates, and the countship of Brittenoro, but a good deal of the territory thus described remained for centuries an object of ambition only on the part of the popes. The actual annexation of Ravenna, Ancona, Bologna, Ferrara, &c., dates from the 16th century. The States of the Church were of course sub merged for a time by the ground swell of the French Revolution, but they appeared again in 1814. In 1849 they received a constitution. On the formation of the kingdom of Italy in 1860 they were reduced to the Comarca of Rome, the legation of Velletri, and the three delegations of Viterbo, Civita Vecchia, and Frosinone, and in 1870 they disappeared from the political map of Europe.

STATICS See **MECHANICS**

STATIONERY Under the name of stationery are embraced all writing materials and implements, together with the numerous appliances of the desk and of mercantile and commercial offices. In addition to these, the term fancy stationery covers a miscellaneous assemblage of leather and other goods, such as pocket books, purses, bags, card-cases, and many kindred objects which cannot be classified. The principal articles and operations of the stationery trade are dealt with in detail under separate headings.

PAPER, PEN, PENCIL, SEALING-WAX, &c, but in connexion with the separate industry of a commercial stationer there are a number of special operations and machines to which brief allusion may be made.

Paper Ruling—The ruling of blue and other coloured lines is usually done on a self feeding machine provided with as many ruling pens as there are lines to be made, and these fixed in parallel order at intervals the width of the ruled spaces. The pens consist of grooved slips of sheet brass coming to a fine point, which in their upper part are covered by a sheet of felt saturated with a flowing ink, whence each pen obtains the supply required for tracing its line. The paper is carried forward by endless tapes or threads which pass around cylinders. In a recent form of machine the rulers consist of metal disks with thin edges, which take up printing ink from an india rubber cylinder, and print the lines on the paper as it passes around a revolving cylinder.

Paper Folding machinery is used for numerous purposes in the stationery trade, apart from its application to the folding of sheets for the bookbinder. Devices for folding come most prominently forward in connexion with the envelope manufacture, an industry which received an enormous development by the introduction of uniform postage rates. In envelope making the folding is commonly associated with gumming, and sometimes with embossing, in the same system of machinery. The first efficient automatic machine for envelope manufacture was devised by Edwin Hill and Warren de la Rue, and by them patented in 1845. Many forms of envelope folding and gumming machines now exist. In making envelopes the blanks are first cut out by shaped cutters or punches acting at one stroke on a thickness of from 200 to 300 sheets of paper. These blanks in the latest form of machine are gummed by a pad which takes gum from a roller and presses it on the edges of the paper, just as printing ink is received from cylinders and pressed on paper in printing. The gummed surface of the pad lifts each blank separately, places it under a plunger, which, descending, passes it to folders, whence it is delivered into a clip in an endless band of considerable length. The envelopes are delivered into the clips in the band at the rate of about 100 to 150 per minute.

Perforating and Punching give rise to a range of machines of varied form and complexity. The idea of perforating paper so as to allow of the ready detaching of portions by tearing was conceived and patented in 1848 by Mr Henry Archer. Of such utility was Mr Archer's conception deemed by the post office authorities as a convenience for detaching stamps from sheets that in 1853 he was awarded £4000 for his patent rights. The applications of perforation are now very numerous, but its value still remains most obvious in connexion with the detachment of adhesive stamps from sheets.

Numbering and Pacing constitute another series of stationery operations, for which ingenious machines have been devised. For consecutive numbering a series of printing disks are employed, on the periphery of which the series of digits 1 to 0 are raised. The outer disk moves a number after each impression, the second disk moves once in ten times, and so on, thus automatically imprinting consecutive numbers up to the limit of the disks on the machine. Such a machine prints only on one side of the paper, and where the numbering is required on both sides the disks must be geared to move in two places, numbering only odd or even numbers, two printings being thus required. For printing right and left consecutively an endless band machine is used, which prints alternately below and above for the two sides of the sheet.

STATISTICS The word "statistic" is derived from the Latin *status*, which, in the so-called Middle Ages, had come to mean a "state" in the political sense. "Statistic," therefore, originally denoted inquiries into the condition of a state. Since the beginning of the 18th century the denotation of the word has been extended so as to include subjects only indirectly connected with political organizations, while at the same time the scope of the investigations it implies has become more definite, and at the present day may be said, for practical purposes, to be fixed, though there are still controversies as to the position of statistical studies in relation to other departments of scientific procedure.

History—The origin of what is now known as "statistic" (See *Die Statistik*, Fr *La Statistique*, Ital *Statistica*) can only be referred to briefly here. As M. Maurice Block has observed in commencing his admirable treatise, "it is no exaggeration to say that statistic has existed ever since there were states." For the first administrative act of the first regular Government was probably to number its fighting men, and its next to ascertain with

some degree of accuracy what amount of taxation could be levied on the remainder of the community. As human societies became more and more highly organized, there can be no doubt that a very considerable body of official statistics must have come into existence, and been constantly used by statesmen, solely with a view to administration. The Romans, who may be described as the most business like people of antiquity, were careful to obtain accurate information regarding the resources of the state, and they appear to have carried on the practice of taking the census, a very comprehensive statistical operation, with a regularity which has hardly been surpassed in modern times. As to the efficiency of the work done we have unfortunately very little information, but those who are curious on the subject may be referred to an article by Dr Hildebrand, entitled "Die antike Bevölkerungsstatistik im alten Rom," printed in the *Jahrbuch für Nationalökonomie und Statistik*, 1866, p. 82.

Statistics, or rather the material for statistics, therefore existed at a very early period, but it was not until within the last three centuries that systematic use of the information available began to be made for purposes of investigation and not of mere administration. According to M. Block, the earliest work in which facts previously known only to Government officials were published to the world was a volume compiled by Francesco Sansovino, entitled *Del Governo et Amministrazione di Diversi Regni et Repubbliche*, which was printed in Venice and bears the date 1583. Other works of a similar kind were published towards the end of the 16th century in Italy and France. Regarding these and other early books on the subject reference may be made to Fallati's *Eintleitung in die Wissenschaft der Statistik*, Dr G. B. Salmson's preface and notes to his translation into Italian of Dr Mayr's work on statistics, and other authors mentioned at the close of this article.

Works on state administration and finance continued to be published during the first half of the 17th century, and the tendency to employ figures, which were hardly used at all by Sansovino, became more marked, especially in England, where the facts connected with "bills of mortality" had begun to attract attention.

In the year 1660 Hermann Conring, "professor of medicine and politics," a rather odd combination, in the university of Helmstedt, was in the habit of giving lectures in which he analysed and discussed the circumstances existing in various countries, in so far as they affected the happiness of the inhabitants. Conring's example was followed by other writers, in Germany and elsewhere, to whom reference is made by Block (*Praxis*, pp. 5, 6) and Haushofer (*Lehr- und Handbuch*, p. 10, note).

The best known member of the "descriptive" school was Achenwall (1719-1772), who is sometimes spoken of as "the father of modern statistics," but, as his procedure was essentially the same as that of Conring, though it was carried out more fully, the title has not been unanimously granted. It is generally admitted, however, that Achenwall's work gave a great impulse to the pursuit of the studies which are now included under the title of statistics. He called his book *Staatsbeschreibung der europäischen Reiche* in the first two editions (1749, 1752), meaning "Constitution of the States of Europe." Subsequently he added "Vornehmsten" and then "heutigen" before "europäischen," evidently with the desire of bringing his work, which may be regarded as the germ of such volumes as the *Statesman's Year-Book*, "up to date." Achenwall is usually credited with being the first writer who made use of the word "statistics," which he applied to his collection of "noteworthy matters regarding the state."

(*Staatsmerkwürdigkeiten*), but the claim has been disputed by M Block, who points out that the term *collegium statisticum* had been previously employed by Schmeitzel, a follower of Conring, whose lectures at Jena were no doubt attended by Achenwall.

In any case statistics, in the modern sense of the word, did not really come into existence until the publication by J P Sussmilch, a Prussian clergyman, of a work entitled *Die göttliche Ordnung in den Veränderungen des menschlichen Geschlechts aus dem Geburt, dem Tode, und der Fortpflanzung desselben erwiesen*. In this book a systematic attempt was made to make use of a class of facts which up to that time had been regarded as belonging to "political arithmetic," under which description some of the most important problems of what modern writers term "vital statistics" had been studied, especially in England. Sussmilch had arrived at a perception of the advantage of studying what Quetelet subsequently termed the "laws of large numbers." He combined the method employed by the Conring-Achenwall school of "descriptive statistics," whose works were not unlike modern school-books of geography, with that of the "political arithmeticians," who had confined themselves to investigations into the facts regarding mortality and a few other similar subjects, without much attempt at generalizing from them.

Political arithmetic had come into existence in England in the middle of the 17th century, or about the time when Conring was instructing the students of Helmstadt. The earliest example of this class of investigation is the work of Captain John Graunt of London, entitled *Natural and Political Annotations made upon the Bills of Mortality*, which was first published in 1666. This remarkable work, which dealt with mortality in London only, ran through many editions, and the line of inquiry it suggested was followed up by other writers, of whom the most distinguished was Sir William Petty, whose active mind was naturally attracted by the prospect of making use of a new scientific method in the class of speculations which occupied him. Sir William was the first writer to make use of the phrase which for nearly a century afterwards was employed to describe the use of figures in the investigation of the phenomena of human society. He called his book on the subject, which was published in 1683, *Five Essays in Political Arithmetick*. Other writers, of whom Halley, the celebrated mathematician and astronomer, was one, entered on similar investigations, and during the greater part of the 18th century the number of persons who devoted themselves to "arithmetical" inquiries into problems of the class now known as statistical was steadily increasing. Much attention was given to the construction of tables of mortality, a subject which had a great attraction for mathematicians, who were eager to employ the newly-discovered calculus of probabilities on concrete problems. Besides Halley, De Moivre, Laplace, and Euler busied themselves with this branch of study. Attempts were also made to deal with figures as the basis of political and fiscal discussion by Arthur Young, Hume, and other historical writers, as well as by the two Mirabeaus.

It is now necessary to return to Sussmilch, who, as already mentioned, endeavoured to form a general theory of society, based on what were then termed "arithmetical" premises, treated nearly on the lines laid down by Achenwall. In modern language, he made use of quantitative aggregate-observation as an instrument of social inquiry. It is true he did not enter on his investigation with an "open mind." He desired to support a foregone conclusion, as the title of his work already mentioned shows. But nevertheless his work was a most valuable one, since it pointed out a road which others who had no desire to

procure evidence in favour of a particular system of thought were not slow to follow. M Block makes the following remarks on the influence exercised on his contemporaries by the work of Sussmilch:—"If the author of the *Göttliche Ordnung* had been a professor his influence would have been much greater than it was. In maintaining that the movement of population is subject to law, that there is a regularity in the recurrence of such phenomena which allows of their being foreseen, he cast into the public mind a leaven which has evidently contributed to the progress of science." Although for many years after the appearance of Sussmilch's book there was a good deal of resistance to the introduction of "arithmetic" as the coadjutor of moral and political investigations, yet, practically there was a tacit admission of the usefulness of figures, even by the chiefs of the so-called "descriptive" school. On the other hand Sussmilch's success was the origin of a "mathematical" school of statisticians, some of whom carried their enthusiasm for figures so far that they refused to allow any place for mere "descriptions" at all. These two schools have now coalesced, each admitting the importance of the point of view urged by the other. They were, however, still perceptibly distinct even as late as 1850, and the ignorant hostility with which many people even among the cultivated classes still regard statistical inquiries into the nature of human society may be regarded as a survival of the much stronger feeling which showed itself among "orthodox" professors of law and economics on the publication of Sussmilch's treatise.

M Block is of opinion that the descriptive school, by whom figures are regarded merely as accessories to and illustrations of the text, would have maintained its position even now but for the establishment of official statistical offices and the influence of the great Belgian Quetelet. Quetelet's work was certainly "epoch-making" in a far higher degree than that of any of his predecessors. To the impulse created by him must be attributed the foundation in 1835 of the Statistical Society of London, a body which, though it has contributed little to the discussion of the theory of statistics, has had a considerable and very useful influence on the practical work of carrying out statistical investigations in the United Kingdom and elsewhere. Quetelet's works were numerous and multifarious, but his most important contribution to the growth of statistical inquiry was his investigation of the theory of probabilities as applied to the "physical and social" sciences, contained in a series of letters to the duke of Saxe-Coburg and Gotha, and published in 1846. Quetelet was above all things an exponent of the "laws of large numbers." He was especially fascinated with the tendency to relative constancy of magnitude displayed by the figures of moral statistics, especially those of crime, which inspired him with a certain degree of pessimism. His conception of an average man (*l'homme moyen*) and his disquisition on the "curve of possibility" were most important contributions to the technical development of the statistical method, though, as M Block observes, their value may have been somewhat exaggerated by subsequent writers (Block, ch. 1, p. 16, and ch. v, p. 112 sq.). It is not possible to enter at length into Quetelet's work in connexion with statistical science. At the close of this article will be found a list including those of his works which are likely to be of use to students of statistics.

The influence exercised by Quetelet on the development of statistics is clearly seen from the fact that, though there is still considerable controversy among statisticians, the old controversy between the "descriptive" and "arithmetical" schools has disappeared, or perhaps we should say has been transformed into a discussion of another kind, the question now at issue being whether there is a science

of statistics as well as a statistical method. It is true that a few books were published between 1880 and 1885 in which the politico-geographical description of a country is spoken of as "statistics," which is thus distinguished from "political arithmetic." The title of Kries's great work, *Die Statistik als selbständige Wissenschaft* (Cassel, 1885), is especially noteworthy as showing that the nature of the controversy was changing. The opponents of Süssmilch maintained that "political arithmetic" ought not to be spoken of as statistics at all. They clung to the conceptions of Conring and Achenwall, to whom "statistics" represented "Staatenkunde" or "Staatszustandskunde," or, as Herzberg, one of Achenwall's followers, called it, "die Kenntniss von der politischen Verfassung der Staaten." Kries claimed that the really "scientific" portion of statistics consisted of the figures employed. As Haushofer says, "his starting point is political arithmetic."

Some eminent statisticians of the latter half of the present century agree with Kries, but the majority of the modern writers on the theory of statistics have adopted a slightly different view, according to which statistics is at once a science relating to the social life of man and a method of investigation applicable to all sciences. This view is ably maintained by Mayr, Haushofer, Gabaglio, and Block, who may be taken to represent the opinions held by the majority of statisticians on the Continent.

Having dealt as far as was possible, within the limits of this article, with the history of statistics, we may here enter a little more minutely into the views of the existing Continental school. This is all the more necessary because, singular to say, there has been no systematic exposition of the subject in England. Isolated dicta have been furnished by high authorities, such as the late Dr W. A. Gny, Prof. Ingram, Sir Rawson W. Rawson, Mr Robert Giffen, and to some extent also by John Stuart Mill, Buckle, Sir George Cornewall Lewis, and other historical and economic writers. There are also monographs on particular points connected with the technique of statistical investigation, such as the contribution made by Mr F. Y. Edgeworth to the discussions at the jubilee of the Statistical Society in 1885, and some of the observations contained in a paper by Mr Patrick Geddes, entitled *An Analysis of the Principles of Economics*, read before the Royal Society of Edinburgh in 1884. Prof. Foxwell has also lectured on the subject of statistics in his capacity of Newmarch lecturer at University College, London. But there has been no attempt to deal with the subject in a systematic way. The practice of statistical inquiry, on the other hand, has been carried on in England with a high degree of success.

With regard to the few invasions of the domain of theory attempted by English writers, it may be observed that the authorities above mentioned are not unanimous. Dr Gny as well as Sir Rawson W. Rawson, who handled the subject with great ability at the jubilee meeting of the London Statistical Society in June 1885, both claim that statistics is to be regarded as an independent science, apart from sociology, while Prof. Ingram, who presided over Section F at the Dublin meeting of the British Association in 1878, maintained that statistics cannot occupy a position co-ordinate with that of sociology, and went on to say that they "constitute only one of the aids or adjuvants of science." Mr Giffen has also expressed himself adversely to the Continental doctrine that there is an independent science of statistics, and this opinion appears to be the correct one, but, as Dr Guy and Sir Rawson W. Rawson have the support of the great body of systematic teaching emanating from distinguished Continental statisticians in support of their view, while their opponents have so far only the *obiter dicta* of a few eminent men to rely upon, it appears needful to examine closely

the views held by the Continental authorities, and the grounds on which they are based.

The clearest and shortest definition of the science of statistics as thus conceived is that of M. Block, who describes it as "la science de l'homme vivant en société en tant qu'elle peut être exprimée par les chiffres." He proposes to give a new name to the branch of study thus defined, namely, "Demography." Mayr's definition is longer. He defines the statistical science as "die systematische Darlegung und Erörterung der thatsächlichen Vorgänge und der aus diesen sich ergebenden Gesetze des gesellschaftlichen menschlichen Lebens auf Grundlage quantitativer Massenbeobachtungen" (the systematic statement and explanation of actual events, and of the laws of man's social life that may be deduced from these, on the basis of the quantitative observation of aggregates). Gabaglio's view is practically identical with those adopted by Mayr and Block, though it is differently expressed. He says "statistics may be interpreted in an extended and in a restricted sense. In the former sense it is a method, in the latter a science. As a science it studies the actual social political order by means of mathematical induction."

This discussion regarding the nature of statistics is to a large extent a discussion about names. There is really no difference of opinion among statistical experts as to the subject-matter of statistics, the only question being—Shall statistics be termed a science as well as a method? That there are some investigations in which statistical procedure is employed which certainly do not belong to the domain of the supposed statistical science is generally admitted. But, as already shown, an attempt has been made to claim that the phenomena of human society, or some part of those phenomena, constitute the subject-matter of an independent statistical science. It is not easy to see why this claim should be admitted. There is no reason either of convenience or logic why the use of a certain scientific method should be held to have created a science in one department of inquiry, while in others the said method is regarded merely as an aid in investigation carried on under the superintendence of a science already in existence. It is impossible to get over the fact that in meteorology, medicine, and other physical sciences statistical inquiries are plainly and obviously examples of the employment of a method, like microscopy, spectrum analysis, or the use of the telescope. Why should the fact of their employment in sociology be considered as authorizing the classification of the phenomena thus dealt with to form a new science?

The most effective argument put forward by the advocates of this view is the assertion that statistics are merely a convenient aid to investigation in the majority of sciences, but are the sole method of inquiry in the case of sociology. Dr Mayr especially (*Gesetzmässigkeit*, &c., p. 14 sq.) makes use of this argument, and illustrates it with his usual ability, but his reasoning is very far from being conclusive. When, indeed, it is tested by reference to the important class of social facts which are named economics, it becomes obvious that the argument breaks down. Economics is a branch—the only scientifically organized branch—of sociology, and statistics are largely used in it, but no one, so far as we are aware, has proposed to call economics a department of statistical science. Sir Rawson W. Rawson, it is true, has boldly proposed to throw over the term "sociology" altogether, and to describe the study of man in the social state as "statistics," but common usage is too firmly fixed to make this alteration of nomenclature practicable even if it were desirable. The existence of the works of Mr Herbert Spencer and Dr Schaffle alone would render the attempted alteration abortive.

Although, however, the above considerations forbid the acceptance of the Continental opinion that the study of man in the social state is identical with statistics, it must be admitted that without statistics the nature of human society could never become known. For society is an aggregate, or rather a congeries of aggregates. Not only that, but the individuals composing these aggregates are not in juxtaposition, and what is, from the sociological point of view, the same aggregate or organ of the "body politic" is not always composed of the same individuals. Constancy of social form is maintained concurrently with the most extensive changes in the collocation and identity of the particles composing the form. A "nation" is really changed, so far as the individuals composing it are concerned, every moment of time by the operation of the laws of population. But the nation, considered sociologically, remains the same in spite of this slow change in the particles composing it, just as a human being is considered to be the same person year by year, although year by year the particles forming his or her body are constantly being destroyed and fresh particles substituted. Of course the analogy between the life of a human being and the life of a human community must not be pressed too far. Indeed, in several respects human communities more nearly resemble some of the lower forms of animal life than the more highly organized forms of animal existence. There are organisms which are fissiparous, and when cut in two form two fresh independent organisms, so diffused is the vitality of the original organism; and the same phenomenon may be observed in regard to human communities.

Now the only means whereby the grouping of the individuals forming a social organism can be ascertained, and the changes in the groups year by year observed, is the statistical method. Accordingly the correct view seems to be that it is the function of this method to make perceptible facts regarding the constitution of society on which sociology is to base its conclusions. It is not claimed, or ought not to be claimed, that statistical investigation can supply the whole of the facts a knowledge of which will enable sociologists to form a correct theory of the social life of man. The statistical method is essentially a mathematical procedure, attempting to give a quantitative expression to certain facts, and the resolution of differences of quality into differences of quantity has not yet been effected even in chemical science. In sociological science the importance of differences of quality is enormous, and the effect of these differences on the conclusions to be drawn from figures is sometimes neglected, or insufficiently recognized, even by men of unquestionable ability and good faith. The majority of politicians, social "reformers," and amateur handlers of statistics generally are in the habit of drawing the conclusions that seem good to them from such figures as they may obtain, merely by treating as homogeneous quantities which are heterogeneous, and as comparable quantities which are not comparable. Even to the conscientious and intelligent inquirer the difficulty of avoiding mistakes in using statistics prepared by other persons is very great. There are usually "pitfalls," even in the simplest statistical statement, the position and nature of which are known only to the persons who have actually handled what may be called the "raw material" of the statistics in question, and in regard to complex statistical statements the "outsider" cannot be too careful to ascertain from those who compiled them as far as possible what are the points requiring elucidation.

The Statistical Method.—This method is a scientific procedure (1) whereby certain phenomena of aggregation not perceptible to the senses are rendered perceptible to the intellect, and (2) furnishing rules for the correct perform-

ance of the quantitative observation of these phenomena. The class of phenomena of aggregation referred to includes only such phenomena as are too large to be perceptible to the senses. It does not, *e.g.*, include such phenomena as are the subject-matter of microscopy. Things which are very large are often quite as difficult to perceive as those which are very small. A familiar example of this is the difficulty which is sometimes experienced in finding the large names, as of countries or provinces, on a map. Of course the terms "large," "too large," "small," and "too small" must be used with great caution, and with a clear comprehension on the part of the person using them of the standard of measurement implied by the terms in each particular case. A careful study of the first few pages of De Morgan's *Differential and Integral Calculus* will materially assist the student of statistics in attaining a grasp of the principles on which standards of measurement should be formed. It is not necessary that he should become acquainted with the calculus itself, or even possess anything more than an elementary knowledge of mathematical science, but it is essential that he should be fully conscious of the fact that "large" and "small" quantities can only be so designated with propriety by reference to a common standard.

Sources whence Statistics are Derived.—The term "statistics" in the concrete sense means systematic arrangements of figures representing "primary statistical quantities." A primary statistical quantity is a number obtained from numbers representing phenomena, with a view to enable an observer to perceive a certain other phenomenon related to the former as whole to parts. They represent either a phenomenon of existence at a given point of time or a phenomenon of accretion during a given period. As examples may be mentioned the number of deaths in a given district during a given time, the number of pounds sterling received by the London and North Western Railway during a given time, and the number of "inches of rain" that fell at Greenwich during a given time. Other examples are the number of tons of pig iron lying in a particular store at a given date, the number of persons residing (the term "residing" to be specially defined) in a given territory at a given date, and the number of pounds sterling representing the "private deposits" of the Bank of England at a given date.

Primary Statistical Quantities are the result of labours carried on either (A) by Governments or (B) by individuals or public or private corporations.

A. Government Statistics.—(1) A vast mass of statistical material of more or less value comes into existence automatically in modern states in consequence of the ordinary administrative routine of departments. To this class belong the highly important statistical information published in England by the registrar general, the returns of pauperism issued by the Local Government Board, the reports of inspectors of prisons, factories, schools, and those of sanitary inspectors, as well as the reports of the commissioners of the customs, and the annual statements of trade and navigation prepared by the same officials. There are also the various returns compiled and issued by the Board of Trade, which is the body most nearly resembling the statistical bureaux with which most foreign Governments are furnished. Most of the Government departments publish some statistics for which they are solely responsible as regards both matter and form, and there are very jealous of their right to do so, a fact which is to some extent detrimental to that uniformity as to dates and periods which should be the ideal of a well-organized system of statistics. Finally may be mentioned the very important set of statistical quantities known as the budget, and the statistics prepared and published by the commissioners of inland revenue, by the post office, and by the national debt commissioners. All these sets of primary statistical quantities arise out of the ordinary work of departments of the public service. Many of them have been in existence, in some form or other, ever since a settled Government existed in the country. There are records of customs receipts at London and other ports of the time of Edward III., covering a period of many years, which leave nothing to be desired in point of precision and uniformity. It may be added that many of these sets of figures are obtained in much the same form by all civilized Governments, and that it is often possible to compare the figures relating to different countries, and thus obtain evidence as to the sociological phenomena of each, but in regard to others there are differences which make comparison difficult.

(2) Besides being responsible for the issue of what may be called administration statistics, all Governments are in the habit of ordering from time to time special inquiries into special subjects.

of interest, either to obtain additional information needful for administrative purposes, or, in countries possessed of representative institutions, to supply statistics asked for by parliaments or congresses. It is not necessary to refer particularly to this class of statistical information, except in the case of the census. This is an inquiry of such great importance that it may be regarded as one of the regular administrative duties of Governments, though as the census is only taken once in a series of years it must be mentioned under the head of occasional or special inquiries undertaken by Governments. In the United Kingdom the work is done by the registrars general who are in office when the period for taking the census comes round. On the Continent the work is carried out by the statistical bureaux of each country,—except France, where it is under the supervision of the minister of the interior. For further information on this subject reference may be made to the excellent chapter in M. Maurice Block's *Traité* entitled "Recensement." See also "Instructions to the Superintendent Registrar of Births and Deaths as to his duties in taking the Census," 1871, also *Census*, vol. 1, p. 334.

B. The primary statistical quantities for which individuals or corporations are responsible may be divided into three categories.

(1) Among those which are compiled in obedience to the law of the land are the accounts furnished by municipal corporations, by railway, gas, water, banking, insurance, and other public companies making returns to the Board of Trade, by trades unions, and by other bodies which are obliged to make returns to the registrar of friendly societies. The information thus obtained is published in full by the departments receiving it, and is also furnished by the companies themselves to their proprietors or members.

(2) An enormous mass of statistical information is furnished voluntarily by public companies in the reports and accounts which, in accordance with their articles of association, are presented to their proprietors at stated intervals. With these statistics may be classed the figures furnished by the various trade associations, some of them of great importance, such as Lloyd's, the London Stock Exchange, the British Iron Trade Association, the London Corn Exchange, the Institute of Bankers, the Institute of Actuaries, and other such bodies too numerous to mention.

(3) There are cases in which individuals have devoted themselves with more or less success to obtaining original statistics on special points. The great work done by Messrs. Behm and Wagner in arriving at an approximate estimate of the population of the earth does not belong to this category, though its results are really primary statistical quantities. Many of these results have not been arrived at by a direct process of enumeration at all, but by ingenious processes of inference. It need hardly be said that it is not easy for individuals to obtain the materials for any primary statistical quantity of importance, but it has been done in some cases with success.

Operations Performed on Primary Statistical Quantities—Only a brief description of matters connected with the technique of the statistical method can be given in this article. In order to form statistics properly, so called the primary statistical quantities must be formed into tables, and in the formation of these tables lies the art of the statistician. It is not a very difficult art when the principles relating to it have been properly grasped, but those who are unfamiliar with the subject are apt to underrate the difficulty of correctly practising it.

Simple Tables—The first thing to be done in the construction of a table is to form a clear idea of what the table is to show, and to express that idea in accurate language. This is a matter which is often neglected, and it is a source of much waste of time and occasionally of misapprehension to those who have to study the figures thus presented. No table ought to be considered complete without a "heading" accurately describing its contents, and it is frequently necessary that such headings should be rather long. It has been said that "you can prove anything by statistics." This statement is of course absurd, taken absolutely, but, like most assertions which are widely believed, it has a grain of truth in it. If this popular saying ran "you can prove anything by tables with slovenly and ambiguous headings," it might be assented to without hesitation. The false "statistical" facts which obtain a hold of the public mind may often be traced to some widely circulated table, to which either from stupidity or carelessness an erroneous or inaccurate "heading" has been affixed.

A statistical table in its simplest form consists of "primaries" representing phenomena of the same class, but existing at different points of time, or coming into existence during different portions of time. This is all that is essential to a table, though other things are usually added to it as an aid to its comprehension. A table stating the number of persons residing in each county of England on a given day of a given year, and also, in another column, the corresponding numbers for the same counties on the corresponding day of the tenth year subsequently, would be a simple tabular statement of the general facts regarding the total population of those counties supplied by two successive censuses. Various figures might, however, be added to it which would greatly add to

its clearness. There might be columns showing the increase or decrease for each county and for the whole kingdom during the ten years, and another column showing what *proportion*, expressed in percentages, these increases or decreases bore to the figures for the earlier of the two years. Then there might be two columns showing what proportions, also expressed as percentages, the figures for each county bore in each year to the figures for the whole kingdom. The nine column table thus resulting would still be simple, all the figures being merely explicit assertions of facts which are contained implicitly in the original "primaries."

Complex Tables—Suppose now we have another table precisely similar in form to the first, and also relating to the counties of England, but giving the number of houses existing in each of them at the same two dates. A combination of the two would form a complex table, and an application of the processes of arithmetic would make evident a number of fresh facts, all of which would be implied in the table, but would not be obvious to most people until explicitly stated.

The technical work of the statistician consists largely in operations of which the processes just referred to are types.

Proportions—The most usual and the best mode of expressing the proportion borne by one statistical quantity to another is to state it as a percentage. In some cases another method is adopted—namely, that of stating the proportion in the form "one in so many." This method is generally a bad one, and its use should be discouraged as much as possible, the chief reason being that the changing portion of this kind of proportional figure becomes greater or less inversely, and not directly, as the phenomenon it represents increases or diminishes.

Averages—Averages or means are for statistical purposes divided into two classes, the *geometrical* and *arithmetical*. An arithmetical mean is the sum of all the members forming the series of figures under consideration divided by their number, without reference to their weight or relative importance among themselves. A geometrical mean is the sum of such figures divided by their number, with due allowance made for their weight. An example will make this clear, and the simplest example is taken from a class of statistical quantities of a peculiar kind—namely, *prices*. The price of a given article is the approximate mathematical expression of the rates, in terms of money, at which exchanges of the article for money were actually made at or about a given hour on a given day. A *quotation of price* such as appears in a daily price list is, if there has been much fluctuation, only a very rough guide to the actual rates of exchange that have been the basis of the successive bargains making up the day's business. But let us suppose that the closing price each day may be accepted as a fair representative of the day's transactions, and let us further suppose that we desire to obtain the *average price* for thirty days. Now the sum of the prices in question divided by thirty would be the arithmetical mean, and its weak point would be that it made no allowance for the fact that the business done on some days is much larger than that done on others, in other words, it treats them as being all of equal weight. Now if, as is actually the case in some markets, we have a daily account of the *total quantities* sold we can weight the members accurately, and can then obtain their geometrical mean. There are cases in which the careless use of arithmetical means misleads the student of the social organism seriously. It is often comparatively easy to obtain arithmetical means, but difficult to obtain geometrical means. Inferences based on the former class of average should be subjected to the most rigid investigation.

Before closing this short survey of the very important subject of averages or means, it is needful to discuss briefly the nature of the phenomena which they may safely be regarded as indicating, when they have been properly obtained. Given a geometric mean of a series of numbers referring to no matter what phenomenon, it is obvious that the value of the mean as a *type* of the whole series will depend entirely on the extent of divergence from it of the members of the series as a body. If we are told that there are in a certain district 1000 men, and that their average height is 5 feet 8 inches, and are told nothing further about them, we can make various hypotheses as to the structure of this body from the point of view of height. It is possible that they may consist of a rather large number of men about 6 feet high, and a great many about 5 feet 5 inches. Or the proportions of relatively tall and short men may be reversed. It is also possible that there may be very few men whose height is exactly 5 feet 8 inches, and that the bulk of the whole body consists of two large groups—one of giants and the other of dwarfs. Lastly, it is possible that 5 feet 8 inches may really give a fair idea of the height of the majority of the men, which it would do if (say) 660 of them were within an inch of that height, either by excess or deficiency, while of the remainder one half were all above 5 feet 9 inches and the other half all below 5 feet 7 inches. This latter supposition would most likely be found to be approximately correct if the men belonged to a race whose average height was 5 feet 8

[illegible]

Part of the exchange has already been made to the point that a certain quantity known as money. Prices in that market are then stated in figures expressing the exchange. In modern times, the terms of exchange are always expressed in money, and the range for the money is established as a certain extent of the general national stock of money. (2) money is always stated in terms of money—being a measure of value, of the exchange, the money or money exchange is only one of the many, and it begins relative to the foreign exchange, the exchange rate of these money in terms of money. All these terms of exchange belong to the same system, which are first made a certain limit by law, as in the case of the money market, are left to be determined by the "law of the market". All these cases of price are connected with the operation of the national market, and the market operation, and for which it is necessary to refer to the law of the market.

These Numbers.—The need for these became conspicuous during the investigations of Toole, Newman, and others into the general statistical movements of the prices of commodities, and to construct a good system of mass may be said to be one of the major statistical aims of the statistical method. In comparing the prices of different years, it was soon observed that, though whole groups of articles moved upwards or downwards simultaneously, they did not all move in the same proportion, and that there were many almost cases in which isolated articles or groups of articles moved in the opposite direction to the majority of articles. The great problem presented to statisticians therefore was and is to devise a statistical expression of the general movement of prices, in which all cases could be adequately represented. The first rough approximation to the desired result was attained by setting down the percentages representing the movements, with their proper algebraic signs before them, and adding them "arithmetically." The total was the proper sign was then divided by the number of articles, and the quotient represented the movement in the prices of the whole body of articles during the period under consideration. It was so soon seen, however, that this procedure was fairly defective, inasmuch as it treated all prices as of equal weight. Certain weights no more than pounds, and none no more than millions. A weighting or improvement was made in the procedure first of giving the prices of several different articles unequal weights, and, next, and other important modifications entered, and only one price came in the case of the number articles and secondly by giving the price of the one commodity representing iron or cotton, and many times that of some number selected for the sake of assigning to these articles their proper relative weights to each other and to the rest. The object was to bring the prices to the same basis—that the numbers attached to the various articles or groups of articles are purely arbitrary, and of like value amounts have been made to obtain what may be called natural index numbers, the most successful so far being that of Mr. Bowley-Giffen, whose index numbers are obtained from the desired value of the unit by an expression into or from the United Kingdom of the articles whose values are desired. In the case of commodities and exports Mr. Giffen worked out the proportion of the value of each article to the value of the whole series of years. During the "manufactured" articles the number of times was then obtained by dividing the value of each article by the proportion of its value to the value of the whole series of years. This procedure is a correct statistical procedure, and is the reason for its being adopted in the statistical systems of most nations employed in the world.

[illegible]

were calculated in the Jan. number of the J. and the Statistical
Section in 1951 as well as the total consumption

The International Use of Statistics.—The absence of uniformity in statistics—that is to say in England and in so-called civilized countries where the quality of the enumeration in every part of a political division is more or less uniform—has been a great obstacle to the progress of statistics. In several Continental countries and in the United States there are statistical bureaus with definite courses to perform. In the United Kingdom, as already remarked, the matter entrusted to a central statistical office is the Commercial and Statistical Department of the Board of Trade, on which the work of furnishing such statistics as are not definitely recognized as being the province of some other state department rests. There are attempts here to be made to introduce more uniformity into the statistics of all countries. It was with this object that statistical congresses have met from time to time since 1852. An endeavor was made at the congress held in 1876 at Budapest to arrange for the publication of a system of international statistics, each statistical bureau undertaking a special branch of the subject. The experiment was, however, found to be only a very partial success, first because all countries were not then and are not yet furnished with central statistical offices and secondly because the work which fell on the offices in existence could only be performed slowly, as the ordinary business of the offices necessarily left them little leisure for extra work. In 1886, at the justice of the London Statistical Society, a number of eminent statistical officials from all parts of the world except Germany were present and the organization was taken to organize an International Institute of Statistics with a view to removing the defects already ascribed to exist in the arrangements made by the congress. The only obstacle to securing a proper representation of all countries was the absence of any German congress, none of the official heads of the German statistical offices being allowed to attend,—apparently on political grounds. Since then assurances of a satisfactory kind have been given to the German Government that their servants would be in no way connected to any course disapproved by their Government if they gave their assistance to the institute from the formation of which it is hoped that much advantage may result. For information as to the constitution and reports of the institute reference may be made to a paper by Dr. F. A. von Neumann-Schlosser in vol. I. (1895) of the *Bulletin of the International Institute of Statistics* (Rome, 1895).

STATIUS, PUBLIUS PAPINUS, Roman poet, lived from about 45 to 95 A.D. so far as can be judged from indications afforded by his poems. He was, to a great extent, born and trained to the profession of a poet. The Statii were of Græco-Campanian origin and were gentle though impoverished and the family records were not without political distinctions. The elder Statius our poet's father was the Orator of his time and taught with distinguished success at Naples and Roma. From boyhood to age he proved himself a champion in the poetic tournaments which formed an important part of the amusements of the early empire. The younger Statius declares that his father was in his time equal to any literary task, whether in prose or verse. Probably our poet inherited a modest competence and was not under the necessity of begging his bread from wealthy patrons. So far as appears he never pursued any occupation but that of poet as poet an occupation in those days as in ours, if we may believe Juvenal and Martial. Statius certainly wrote poems to order (as *Silva* = 1. 2. 11. 1. and 11. 4) but there is no indication that the material return for them was important to him. In his seventh satire Juvenal speaks of the immense public enthusiasm which attended the recitation of the *Phædra* when the benches "were breaking" with applause but the poet he says might have starved had not Pansa the favourite comedian of the day bought from him the libretto of a comic opera. This reference

of Juvenal deserves, however, as little to be accepted literally as his misleading allusions to Quintilian in the same satire. Of events in the life of Statius we know little. He married early a young widow, for whom he expresses tender affection in some of the few obviously sincere verses he ever wrote. From his boyhood he was victorious in poetic contests,—many times at his native city Naples, three at Alba, where he received the golden crown from the hand of the emperor. But at the great Capitoline competition (probably on its third celebration in 94 A.D.) Statius failed to win the coveted chaplet of oak leaves. No doubt the extraordinary popularity of his *Thebais* had led him to regard himself as the supreme poet of the age, and when he could not sustain this reputation in the face of rivals from all parts of the empire he accepted the judges' verdict as a sign that his day was past, and retired to Naples, the home of his ancestors and of his own young days. We still possess the poem he addressed to his wife on this occasion (*Silv.*, in 5). It was a hard task to overcome her objections to turning her back upon the great capital. Chief among them was that which arose from a fear lest it should prove difficult to find in Naples a husband for her daughter (by her first marriage, she had no children by Statius). There are hints in this poem which naturally lead to the surmise that Statius was suffering from a loss of the emperor's favour, he may have felt that a word from Domitian would have won for him the coveted garland, and that the word ought to have been given. In the preface to book iv of the *Silvae* there is mention of detractors who hated our poet's style, and these may have succeeded in inducing a new fashion in poetry at court. Such an eclipse, if it happened, must have cut Statius to the heart. He appears to have relished thoroughly the rôle of court-poet. The statement sometimes made that the elder Statius had been the emperor's teacher, and had bestowed many favours on him, so that the son inherited a debt of gratitude, seems to have no solid foundation. Statius lauds the emperor, not to discharge a debt, but rather to create an obligation. His flattery is as far removed from the gentle propitiatory tone of Quintilian as it is from the coarse and crawling humiliation of Martial. It is in the large extravagant style of a nature in itself healthy and generous, which has accepted the theme and left scruples behind. In one of his prefatory epistles Statius declares that he never allowed any work of his to go forth without invoking the godhead of the divine emperor. The poem on the equestrian statue of Domitian set up on the Capitol (*Silv.*, i 1) is such colossal rodomontade that if the emperor had had a grain of humour in his composition he must have died of merriment on receiving it. Statius had taken the full measure of Domitian's gross taste, and carefully puts conscience and sincerity out of view, lest some uneasy twinge should mar his master's enjoyment. But in one poem, that in which the poet pays his due for an invitation to the imperial table, we have sincerity enough. Statius clearly feels all the raptures he expresses. He longs for the power of him who told the tale of Dido's banquet, and for the voice of him who sang the feast of Alcinous, that he may give forth utterance worthy of the lofty theme. The poet seemed, he says, to dine with great Jove himself and to receive nectar from Ganymede the cup-bearer (an odious reference to the imperial favourite Eearnus). All his life hitherto has been barren and profitless. Now only has he begun to live in truth. "O ruler over all the lands, and mighty father of the world which thou hast conquered, do I, recumbent, see thee, thou hope of all mankind, and nursing of all the gods? Is it mine to gaze from near at hand on thy features, with the wine-cup and the feast

beside me, while I am forbidden to rise?" The palace struck on the poet's fancy like the very hall of heaven, nay, Jove himself marvels at its beauty, but is glad that the emperor should possess such an earthly habitation, he will thus feel less desire to seek his destined abode among the immortals in the skies. Yet even so gorgeous a palace is all too mean for his greatness and too small for his vast presence. "But it is himself, himself, that my eager eye has alone time to scan. He is like a resting Mars or Bacchus or Alcides." Martial too swore that, were Jove and Domitian both to invite him to dinner for the same day, he would prefer to dine with the greater potentate on the earth. Pliny, however, has sketched for us the state dinners of Domitian, where the coarse contempt of the tyrant overclouded the guests, and where a man who still respected himself had torments to endure. Martial and Statius were no doubt supreme among the imperial flatterers. Each was the other's only serious rival. It is therefore not surprising that neither should breathe the other's name. Even if we could by any stretch excuse the bearing of Statius towards Domitian, he could never be forgiven the poem entitled "The Hair of Flavius Eearnus," Domitian's Ganymede (*Silv.*, in 4), a poem than which it would be hard to find a more repulsive example of real poetical talent defiled for personal ends. Well for Statius that he did not, like Martial, live on into the days of Nerva to write sorry palmodes! Every thing points to the conclusion that he did not survive his emperor—that he died, in fact, a short time after leaving Rome to settle in Naples. Apart from the emperor and his minions, the friendships of Statius with men of high station seem to have been maintained on fairly equal terms. He was clearly the poet of society in his day as well as the poet of the court.

As poet, Statius unquestionably shines in many respects when compared with the other post-Augustans. He was born with exceptional talent, and his poetic expression is, with all its faults, richer on the whole and less forced, more buoyant and more felicitous, than is to be found elsewhere in the Silver Age of Latin poetry. Statius is at his best in his occasional verses, the "*Silvae*," which have a character of their own, and in their best parts a charm of their own. The title was proper to verses of rapid workmanship, on everyday themes. Statius prided himself on his powers of improvisation, and he seems to have been quite equal to the Horatian feat of dictating two hundred lines in an hour, while standing on one leg. The improvisatore was in high honour among the later Greeks, as Cicero's speech for the poet Archias indicates, and the poetic contests common in the early empire did much to stimulate ability of the kind. Statius speaks of his "*Silvae*" (preface to book i) as having "streamed from him under the influence of sudden inspiration, and with a certain pleasure due to their rapidity." No one poem occupied more than two days, some came to birth at the dinner table, many while the poet's friend Pollus sat by his side, and shuddered at the audacity of his pen (preface to book iii.) It is to this velocity that the poems owe their comparative freshness and freedom, along with their loose texture and their inequality. There are thirty-two poems, divided into five books, each with a dedicatory epistle. Of nearly four thousand lines which the books contain, more than five-sixths are hexameters. Four of the pieces (containing about 450 lines) are written in the hendecasyllabic metre, the "tragic metre of Catullus," and there is one Alcian and one Sapphic ode. But the poems in these metres are merely the experiments of a poet who knows well that his strength lies in the hexameter, which in his hands shows greater freedom, variety, and music than it exhibits when handled by other poets of the Silver Latin Age. The subjects of the "*Silvae*" are very various. Five poems are devoted to flattery of the emperor and his favourites, but of these enough has already been said. Six are lamentations for deaths, or consolations to survivors. Statius seems to have felt a special pride in this class of his productions, and certainly, notwithstanding the excessive and conventional employment of pretty mythological pictures, with other affectations, he sounds notes of pathos such as only come from the true poet. There are oftentimes traits of an almost modern domesticity in these verses, and Statius the childless, has here and there touched on the charm of childhood in lines for a parallel to which, among the ancients, we must go, strange to say, to his rival Martial. One of the *epicidia*, that on Priscilla the wife of Abascantus, Domitian's freedman (*Silv.*, v 1), is full of interest for the picture it presents of the official activity of a high

officer of state. Another group of the "*Silvae*" give picturesque descriptions of the villas and gardens of the poet's friends. In these we have a more vivid representation than elsewhere of the surroundings amid which the grandees of the early empire lived when they took up their abode in the country. It was of these pieces that Niebuhr thought when he said that the poems of Statius are charming to read in Italy. They exhibit, better even than Pliny's well-known letters, the passion of the rich Roman for so constructing his country house that light, air, sun, and leafage should subserve his luxury to the utmost, while scope was left for displaying all the resources of art which his wealth enabled him to command. As to the rest of the "*Silvae*," the congratulatory addresses to friends are graceful but commonplace, nor do the jocosse pieces call for special mention here. In the "*Kalendae Decembres*" we have a striking description of the gifts and amusements provided by the emperor for the Roman population on the occasion of the Saturnalia. In his attempt at an epithalamium (*Silv.*, 1. 2) Statius is forced and unhappy. But the birthday ode in Lucan's honour (*Silv.*, 11. 7) has, along with the accustomed exaggeration, many powerful lines, and shows high appreciation of preceding Latin poets. Some phrases, such as "the untaught muse of high sonled Ennius" and "the lofty passion of sage Lucretius," are familiar words with all scholars. The ode ends with a great picture of Lucan's spirit rising after death on wings of fame to regions whither only powerful souls can ascend, scornfully surveying earth and smiling at the tomb, or reclining in Elysium and singing a noble strain to the Pompeys and the Catos and all the "Pharsalian host," or with proud tread exploring Tartarus and listening to the wailings of the guilty, and gazing at Nero, pale with agony as his mother's avenging torch glitters before his eyes. It is singular to observe how thoroughly Nero had been struck out of the imperial succession as recognized at court, so that the "bald Nero" took no umbrage when his flatterer in chief profanely dealt with his predecessor's name.

The epic poems of Statius are less interesting because cast in a commoner mould, but they deserve study in many respects. They are the product of long elaboration. The "*Thebais*," which the poet says took twelve years to compose, is in twelve books, and has for its theme the old "tale of Thebes"—the deadly strife of the Theban brothers. There is also preserved a fragment of an "*Achilleis*," consisting of one book and part of another. In the weary length of these epics there are many flowers of pathos and many little finished gem pictures, but the trammels of tradition, the fashionable taste, and the narrow bars of education check continually the poet's flight. The public idea of what an epic poem should be was firmly fixed, and Statius would not have towered above the thousand poets of his day in the estimation of his countrymen had he not given full embodiment to the idea. Not merely were the materials for his epics prescribed to him by rigid custom, but also to a great extent the method by which they were to be treated. All he could do was to sound the old notes with a distinctive timbre of his own. The gods must needs wage their wonted epic strife, and the men, their puppets, must dance at their nod, there must needs be heavenly messengers, portents, dreams, miracles, single combats, smiles, Homeric and Virgilian echoes, and all the other paraphernalia of the conventional epic. But Statius treats his subjects with a boldness and freedom which contrast pleasingly with the timid traditionalism of Silius Italicus and the stiff scholasticism of Valerius Flaccus. The vocabulary of Statius is conspicuously rich, and he shows audacity, often successful, in the use of words and metaphors. At the same time he carried certain literary tricks to an aggravating pitch, in particular the excessive use of alliteration, and the misuse of mythological allusion. The most well-known persons and places are described by epithets or periphrases derived from some very remote connexion with mythology, so that many passages are as dark as Horacutus. The "*Thebais*" is badly constructed. The action of the epic is hindered and stopped by enormous episodes, one of which fills one-sixth of the poem. Nor had Statius a firm grasp or clear imagination of character. So trying are the late ancient epics to a modern reader that he who has read any one of the three—Statius, Silius, and Valerius (Lucan stands apart)—will with difficulty be persuaded to enter on the other two. Yet, if he honestly reads them all, he can hardly fail to rank Statius the highest of the three by a whole sphere.

The *editio princeps* of the epics is dated 1470, of the *Silvae* 1472. Notable editions since have been those of Bernartius (*Antwerp*, 1695), Gronovius (1662), Kohnmann, the *Silvae* by Baehrens. Among editions of portions of Statius's works, that of the *Silvae* by Jeremiah Markland, fellow of Peterhouse in Cambridge (1729), deserves special attention. The brilliance and erudition of the work of the *Thebais* and *Achilleis* was begun by O. Müller (1870) but not completed. The condition of the text of the *Silvae* is one of the most curious facts in the history of ancient literature. Poggio discovered a MS at St Gall and brought it into Italy. This MS has disappeared, but from it are derived all our existing MSS., except one of the birthday ode to Lucan, now at Florence and of the 10th has come down to us, and is the principal basis of the text. The MSS. of the epics are numerous, as was to be expected from their great popularity in the Middle Ages to which Dante is witness (see *Purg.*, xxi., where an interview with the shade of Statius is described at some length) (J. S. R.)

STATUTE, or Act of Parliament, is a law made by the sovereign power in the state, that is, the king, by and with the advice and consent of the lords spiritual and temporal and commons in parliament assembled. It forms a part of the *lex scripta*, or written law, which by English legal authorities is used solely for statutory law, a sense much narrower than it bore in Roman law. To make a statute the concurrence of the crown and the three estates of the realm is necessary. Thus a so-called statute of 5 Ric II c 5, directed against the Lollards, was afterwards repudiated by the Commons as passed without their assent. The validity of a statute was indeed at times claimed for ordinances such as that just mentioned, not framed in accordance with constitutional rule, and was actually given to royal proclamations by 31 Hen VIII c 8. But this Act was repealed by 1 Edw VI c 12, and since that time nothing but a statute has possessed the force of a statute, unless indeed certain rules or orders depending ultimately for their sanction upon a statute may be said to have such force. Examples of what may be called indirect legislation of this kind are orders in council (see PRIVY COUNCIL), by-laws made under the powers of the Public Health Act, and rules of court such as those made under the powers of the Judicature Acts and Acts of Sederunt of the Court of Session.

The history of statutory legislation and the modern procedure by which bills become statutes are sufficiently treated under ACT OF PARLIAMENT and PARLIAMENT. It is proposed in this place to deal with the legal rather than the political aspect of the subject, and to give a short list of some of the more important statutes which have been passed by the legislature.

The list of statutes as at present existing begins with the Statute of Merton, 1235¹. Many of the earlier statutes are known by the names of the places at which they were passed, e.g., the Statutes of Merton, Marlbridge, Gloucester, Westminster, or by their initial words, e.g., *Quia Emptores*, *Circumspecte agatis*. The earliest existing statute roll is 6 Edw I (the Statute of Gloucester). After 4 Hen VII. the statute roll ceased to be made up, and enrolments in Chancery (first made in 1485) take its place. Some of the Acts prior to the Statute of Gloucester are of questionable authority, but have gained recognition by a kind of prescription.

All statutes were originally public, irrespectively of their subject matter. The division into public and private dates from the reign of Richard III. At present statutes are of four kinds—public general Acts, public local and personal Acts, private Acts printed by the queen's printers, and private Acts not so printed. The division into public general and public local and personal rests upon a resolution of both Houses of Parliament in 1798. In 1815 a resolution was passed in accordance with which private Acts are printed, with the exception of name, estate, naturalization, and divorce Acts. The last two are now practically superseded by the provisions of the Divorce Act, 1857, and the Naturalization Act, 1870. Since 1815 it has been usual to refer to public general Acts by Arabic numerals, e.g., 5 and 6 Vict c 21, public local and personal Acts by small Roman numerals, e.g., 5 and 6 Vict. c. xxi. Each Act is strictly but a chapter of the legislation of the session, which is regarded as composing a single Act divided into chapters for convenience, the chapters themselves being also called Acts. The citation of previous Acts is provided for by 13 and 14 Vict c 21, § 3. It is now usual for each chapter or Act to contain

¹ Ruffhead's edition of the statutes begins with the Magna Carta of 1225. But in the *Revised Statutes* that form of Magna Carta which is now law appears as a statute of the year 1297. It is often known as *Confirmatio Cartarum*, and is a recital and confirmation by Edward I of the chief provisions of John's charter.

a short title by which it may be cited, *e.g.*, the Elementary Education Act, 1870. Sometimes a series of Acts is grouped under a generic title, *e.g.*, the Merchant Shipping Acts, 1854 to 1883.¹ 8 and 9 Viet. c. 113, § 3, makes evidence the queen's printers' copies of private and local and personal Acts. A private Act not printed by the queen's printers is proved by an examined copy of the parliament roll. A public Act binds all subjects of the realm, and need not be pleaded (except where the law from motives of policy specially provides for pleading certain Acts, as in the defences of not guilty by statute, the Statute of Frauds, and the Statute of Limitations). A private Act must generally be pleaded, and does not as a rule bind strangers to its provisions. Formerly an Act took effect from the first day of the session in which it was passed. The hardship caused by this technical rule has been obviated by 33 Geo. III. c. 13, by which an Act takes effect from the day on which it receives the royal assent, where no other date is named. This has been held to mean the beginning of the day, so as to govern all matters occurring on that day. An Act cannot in the strict theory of English law become obsolete by disuse. Nothing short of repeal can limit its operation. The law has, however, been interpreted in some recent cases with somewhat less rigour. In the case of a prosecution for blasphemy in 1883 (*Reg. v. Ramsay*) Lord Coleridge said, "though the principles of law remain unchanged, yet (and it is one of the advantages of the common law) their application is to be changed with the changing circumstances of the times."² This would be applicable as much to the interpretation of statutes as to other parts of the common law. The title, preamble, and marginal notes are strictly no part of a statute, though they may at times aid in its interpretation.

Besides the fourfold division above mentioned, statutes are often classed according to their subject-matter, as perpetual and temporary, penal and beneficial, imperative and directory, enabling and disabling. Temporary Acts are those which expire at a date fixed in the Act itself. Thus the Army Act is passed annually and continues for a year, the Ballot Act, 1872, expired at the end of 1880, and the Regulation of Railways Act, 1873, at the end of five years. By means of these temporary Acts experimental legislation is rendered possible in many cases where the success of a new departure in legislation is doubtful. In every session an Expiring Laws Continuance Act is passed for the purpose of continuing (generally for a year) a considerable number of these temporary Acts. By 48 Geo. III. c. 106 a continuing Act is to take effect from the date of the expiration of a temporary Act, where a bill for continuing the temporary Act is in parliament, even though it be not actually passed before the date of the expiration.

Penal Acts are those which impose a new disability, beneficial those which confer a new favour. An imperative statute (often negative or prohibitory in its terms) makes a certain act or omission absolutely necessary, and subjects a contravention of its provisions to a penalty. A directory statute (generally affirmative in its terms) recommends a certain act or omission, but imposes no

penalty on non-observance of its provisions. To determine whether an Act is imperative or directory the Act itself must be looked at, and many nice questions have arisen on the application of the rule of law to a particular case.

Enabling statutes are those which enlarge the common law, while disabling statutes restrict it. This division is to some extent coincident with that into beneficial and penal. Declaratory statutes, or those simply in affirmance of the common law, were at one period not uncommon, but they are now practically unknown. The Statute of Treasons of Edward III. is an example of such a statute. Statutes are sometimes passed in order to overrule specific decisions of the courts. Examples are the Factors Act, 1877, the Territorial Waters Jurisdiction Act, 1878, the Sale of Food and Drugs Act, 1879.

The construction or interpretation of statutes depends partly on the common law, partly on statute. The main rules of the common law, as gathered from the best authorities, are these: (1) Statutes are to be construed, not according to their mere letter, but according to the intent and object with which they were made. (2) The relation of the statute to the common law is to be considered. In the words of the resolution of the Court of Exchequer in *Heydon's Case*, 3 *Coke's Rep.* 7, the points for consideration are—"1, What was the common law before the making of the Act? 2, What was the mischief and defect against which the common law did not provide? 3, What remedy the parliament hath resolved and appointed to cure the disease of the Commonwealth? 4, The true reason of the remedy." (3) Beneficial or remedial statutes are to be liberally, penal more strictly, construed. (4) Other statutes *in pari materia* are to be taken into consideration. (5) A statute which treats of persons of inferior rank cannot by general words be extended to those of superior rank. (6) A statute does not bind the crown, unless it be named therein. (7) Where the provision of a statute is general, everything necessary to make such provision effectual is implied. (8) A later statute repeals an earlier, as far as the two are repugnant, but, if they may stand together, repeal will not be presumed. (9) There is a presumption against creation of new or ousting of existing jurisdictions, against impairing obligations, against retrospective effect, against violation of international law, against monopolies, and in general against what is inconvenient or unreasonable. (10) If a statute inflicts a penalty, the penalty implies a prohibition of the act or omission for which the penalty is imposed. Whether the remedy given by statute is the only one depends on the words of the particular Act. In some cases an action or an indictment will lie, in others the statutory remedy, generally summary, takes the place of the common law remedy. In some few instances the courts have construed the imposition of a penalty as operating not to invalidate a contract but to create a tax upon non-compliance with the terms of the statute. What may be called the statutory rules of construction provide, *inter alia*, that any Act referring to England includes Wales and Berwick-upon-Tweed (20 Geo. II. c. 42), and that all words importing the masculine gender shall be taken to include females, and the singular to include the plural and the plural the singular (13 & 14 Viet. c. 21, § 4). The same Act further provides that, where any Act repealing in whole or in part any former Act is itself repealed, such last repeal shall not revive the Act or provisions before repealed unless words be added to that effect (§ 5), and that, wherever any Act shall be made repealing in whole or in part any former Act and substituting some provision or provisions instead of the provision or provisions repealed, such provision or pro-

¹ A short title has been occasionally given by retrospection to an Act which did not originally possess it. For instance, the Conveyancing Act, 1881, enacts that the Act of 5 and 6 Will. IV. c. 62, the original title of which is of unwieldy length, may be cited for the future as the Statutory Declarations Act, 1835. In some cases the title has been changed. Thus the name of the Summary Procedure (Scotland) Act, 1864, was changed in 1881 to that of the Summary Jurisdiction Act, 1864.

² This opinion carries out to a certain extent the view of Locke, who in Article 79 of his Carolina Code recommended the determination of Acts of the legislature by effluxion of time after a hundred years from their enactment.

visions so repealed shall remain in force until the substituted provision or provisions shall come into operation by force of the last Act (§ 6). Numerous interpretations of particular words are contained in Acts of Parliament, either general, as "month," "county," "land," and other words in 13 and 14 Vict. c. 21, § 4, or for the purposes of the Act, as "settlement" for the purposes of the Settled Land Act, 1882.

The earlier Acts are generally simple in character and language, and comparatively few in number. At present the number passed every session is enormous, in the session of 1885 it was 80 general and 190 local and personal Acts. Without going as far as to concede with an eminent legal authority that of such legislation three-fourths is unnecessary and the other fourth mischievous, it may be admitted that the immense library of the statutes would be but a trackless desert without trust worthy guides. Revision of the statutes was evidently regarded by the legislature as desirable as early as 1563 (see the preamble to 5 Eliz. c. 4). It was demanded by a petition of the Commons in 1610. Both Coke and Bacon were employed for some time on a commission for revision. At times Consolidation Acts in the nature of digests of law (generally amending as well as consolidating) were passed, such as the Merchant Shipping Act, 1854, and the Criminal Law Consolidation Acts of 1861. The most important action, however, was the nomination of a revision committee by Lord Chancellor Cairns in 1868, the practical result of which has been the issue of an edition of the *Revised Statutes* in eighteen volumes, bringing the revision of statute law down to 1878. This edition is of course subject to the disadvantage that it becomes less accurate every year as new legislation appears. An index to the statutes which are still law is published about every three years by the Council of Law Reporting.

The principal statutes may be classified under various heads according to the matter with which they deal. It should be remembered at the same time that many of them—Magna Carta, for example—might fall with equal correctness under more than one head. A division, convenient, if not exhaustive, would be into historical constitutional, legal, and social.

Historical—Under this head would come those Acts which to a greater or less extent mark important epochs in the national history, such as the Statute of Rhuddlan, the Acts of Union defining the relations of Wales, Scotland, and Ireland to England, the Act of Settlement, the Stamp Act of 1765—the proximate cause of the revolt of the American colonies,—the Acts abolishing the slave trade and the corn laws, and those defining the position of dependencies, such as the Act for the Better Government of India, 1858, and the British North America Act, 1867.

Constitutional—The principal Acts of this class would be Magna Carta, the statutes *De Tallagio non Concedendo* and *De Privilegiis Regis* and those dealing with mortmain and treason, the Petition of Right, the Bill of Rights, the Septennial Act, the Royal Marriage Act, the Mutiny, Militia, Naval Discipline, and Foreign Enlistment Acts, and the Acts affecting the parliamentary franchise from the time of Henry VI. to the Redistribution of Seats Act, 1885. Under this head too might be placed the numerous Acts dealing with the question of religion. Some of the more interesting of these are the *Articuli Cleri*, the Statutes of Provisors, the Acts of Henry VIII. abolishing monasteries, the Acts of Supremacy and Uniformity of Henry VIII., Elizabeth, and Charles II., the Toleration, Catholic Emancipation, Tithe Commutation, Church Discipline, Public Worship Regulation, Irish Church, and Scottish Patronage Abolition Acts.

Legal—The most important of this class are perhaps

the Statutes of *Quia Emptores* and *De Donis*, the Statutes of Uses and of Wills, the Statutes of Limitation, the Statute of Frauds and its amendments, the Fines and Recoveries Act, the Conveyancing, Settled Land and Settled Estates, and Married Women's Property Acts, and the Acts for the amendment of procedure, *e.g.*, the Chancery Amendment, Common Law Procedure, Judicature, and Appellate Jurisdiction Acts.

Social—Social legislation (other than mere sumptuary laws) is of comparatively modern introduction. Among earlier instances are the Statute of Labourers of Edward III. and the Poor Law of Elizabeth. More modern examples are the Factory, Public Health, and Artisans' Dwellings Act, and, perhaps greatest of all, the Education Acts. Besides these there are the Acts dealing with patent, copyright, summary jurisdiction, friendly and building societies, trades unions, savings banks, theatres, commons preservation, and agricultural holdings. Acts which have trade for their special object are the Bank Charter, Merchant Shipping, Bills of Lading, Bills of Exchange, Crossed Cheques, Factors, Stamp, Licensing, Bankruptcy, and Trade Marks Acts.

The chief editions of the statutes are the *Statutes of the Realm* printed by the queen's printers, Ruffhead's, and the fine edition issued from 1810 to 1824 in pursuance of an address from the House of Commons to George III. The safest authority is of course the *Revised Statutes*. Chitty's collection of statutes of practical utility is a useful compilation. Among the earlier works on statute law may be mentioned the readings on statutes by great lawyers, such as the second volume of Coke's *Institutes*, Bacon's *Reading on the Statute of Uses*, Barrington's *Observations on the more Ancient Statutes from Magna Carta to the 21 Jac. I. c. 27* (5th ed. 1796), and the Introduction to Blackstone's *Commentaries*. Among the later works are the treatises of Dwarria (2d ed. 1848) and Sir P. B. Maxwell (2d ed. 1883) on the interpretation of statutes, and Sir H. Thring's *Practical Legislation, on the Composition and Language of Acts of Parliament*.

Scotland—The statutes of the Scottish parliament before the Union differed from the English statutes in two important respects,—they were passed by the estates of the kingdom sitting together and not in separate Houses, and from 1367 to 1690 they were discussed only after preliminary consideration by the Lords of Articles. An Act of the Scottish parliament may in certain cases cease to be binding by desuetude. "To bring an Act of Parliament like those we are dealing with" (*i.e.*, the Sabbath Profanation Acts) "into what is called in Scotch law the condition of desuetude, it must be shown that the offence prohibited is not only practised without being checked, but is no longer considered or dealt with in this country as an offence against law" (Lord Justice General Inghs in *Bates Case*, 1 *Couper's Rep.*, 495). Acts of the imperial parliament passed since the Union extend in general to Scotland, unless that country be excluded from their operation by express terms or necessary implication.

Ireland—Originally the lord deputy appears to have held parliaments at his option, and their Acts were the only statutory law which applied to Ireland, except as far as judicial decisions had from motives of policy extended to that country the obligation of English statutes. In 1495 the Act of the Irish parliament known as Poyning's Law or the Statute of Drogheda enacted that all statutes lately made in England be deemed good and effectual in Ireland. This was construed to mean that all statutes made in England prior to the 18 Hen. VII. were valid in Ireland, but none of later date were to have any operation unless Ireland were specially named therein or unless adopted by the Irish parliament (as was done, for instance, by Yelverton's Act, 21 and 22 Geo. III. c. 48, 1.). Another article of Poyning's Law secured an initiative of legislation to the English privy council, the Irish parliament having simply a power of acceptance or rejection of proposed legislation. The power of the parliament of Great Britain to make laws to bind the people of Ireland was declared by 6 Geo. I. c. 5. This Act and the article of Poyning's Law were repealed in 1782, and the short lived independence of the parliament of Ireland was recognized by 23 Geo. III. c. 28. The application of Acts passed since the Union is the same as in the case of Scotland.

Colonies and Dependencies—Acts of the imperial parliament do not extend to the Isle of Man, the Channel Islands, or the colonies, unless they are specially named therein. By 28 and 29 Viet c 63 any colonial law repugnant to the provisions of any Act of Parliament extending to the colony is void to the extent of such repugnance, and no colonial law is to be void by repugnance to the law of England unless it be repugnant to such an Act of Parliament. For colonies without representative legislatures the crown usually legislates, subject to the consent of parliament in particular cases. For instance, it was the opinion of the judicial committee of the privy council in 1876 that a cession of British territory in India to a native state would probably need the concurrence of the imperial parliament (*Damodhar Gordhan v Deoram Kanji Law Rep., 1 Appeal Cases, 332*).

United States—By the constitutions of many States English statute law, as it existed at the time of the separation from England, and as far as it is applicable, has been adopted as part of the law of the States. The United States and the State are not bound by an Act of Congress or a State law unless specially named. The States legislate for themselves within the limits of their own constitution and that of the United States. Here appears the striking difference between the binding force of a statute of the United Kingdom and an Act passed by congress or a State legislature. In the United Kingdom parliament is supreme, in the United States an Act is only of authority if it is in accordance with the constitution. The courts may declare an Act void if it contravene the constitution of the United States or of a State, so that practically the Supreme Court of the United States is the ultimate legislative authority. Examples of recent cases where the constitutionality of an Act has been contested will be found under *PAYMENT* and *PUNISHMENT*. The restrictions upon legislation contained in the constitution of the United States provide against the suspension of the writ of habeas corpus, except in case of rebellion or invasion, the passing of a bill of attainder or *ex post facto* law, the imposition of capitation or other direct tax, unless in accordance with a previous article of the constitution, or of a tax or duty on exports, the preference of the ports of one State over those of another, the drawing of money from the treasury except by appropriations made by law, and the grant of a title of nobility. The amended constitution contains further limitations, e.g., the taking of private property for public use without just compensation, and the abridging of the right of citizens on account of race, colour, or previous condition of servitude. State legislation is limited by § 10—"No State shall make anything but gold and silver coin a tender in payment of debts, pass any bill of attainder, *ex post facto* law, or law impairing the obligation of contracts, or grant any title of nobility." The section further forbids imposition of duties on imports or exports or any duty of tonnage without consent of congress. State constitutions often contain further restrictions, among the more usual are provisions against laws with a retrospective operation, or impairing the obligation of contracts, or dealing with more than one subject to be expressed in the title. The time when a statute is to take effect after its passing is often fixed by State constitutions. The statutes of the United States were revised under the powers of an Act of Congress passed in 1874 (sess. 1 c 333), and the volume of *Revised Statutes* (frequently amended since) was issued on February 22, 1875. Many of the States have also issued revised editions of their statutes. The rules of construction are in general agreement with those adopted in England. See *Sedgwick, Statutory Law*.

International Law—The term statute is used by international jurists and civilians to denote the whole body of the municipal law of the state. In this sense statutes are either real, personal, or mixed. A real statute is that part of the law which deals directly with property, whether movable or immovable. A personal statute has for its object a person, and deals with questions of status, such as marriage, legitimacy, or infancy. A mixed statute affects both property and person, or, according to some authorities, it deals with acts and obligations. Personal statutes are of universal validity, real statutes have no extra territorial authority. The determination of the class under which a particular law ought to fall is one of great difficulty, and one in which there is often a conflict of legal opinion. On the whole the division appears to have created more difficulties than it has solved, and it is rejected by Savigny as unsatisfactory. See *Story, Conflict of Laws*, §§ 12-16, Phillimore, *International Law*, vol. iv ch. xvi. (J Wt.)

STATUTE MERCHANT AND STATUTE STAPLE were two old forms of security, long obsolete in practice, though references to them still occur in some modern statutes. They were originally permitted only among traders, for the benefit of commerce, but afterwards extended by 23 Hen VIII c 6 to all subjects, whether traders or not. The creditor under either form of security was allowed to seize the goods and hold the lands of a

defaulting debtor until satisfaction of his debt. While he held the lands he was termed tenant by statute merchant or by statute staple. In addition to the loss of his goods and lands the debtor was liable to be imprisoned.

STAUNTON, a city of the United States, the county-seat of Augusta county, Virginia, lies at the foot of the Blue Ridge Mountains, on the Lewis Creek (a tributary of the Shenandoah), 136 miles west-north-west of Richmond. It is the seat of the State lunatic asylum and of the State institution for the deaf and dumb and blind, and has besides an unusual number of important educational establishments. Iron-works, planing-mills, and flour mills represent the manufacturing interest. The population was 5120 in 1870 and 6664 in 1880.

STAUNTON, HOWARD (1810-1874), Shakespearean scholar and writer on chess, was born about 1810. He was educated at Eton and Oxford, but left the university without taking a degree and settled in London, devoting much of his attention to the study of the English dramatists of the Elizabethan age. In conjunction with this he also took a great interest in the stage, and as an amateur once played Lorenzo to the Shylock of Edmund Kean. Between 1857 and 1860 he edited in monthly parts an edition of Shakespeare published by Routledge, which has been several times reissued, and must be ranked as superior, as regards both text and notes, to any previously published. His skill as a Shakespearean commentator, combining in a remarkable degree the acuteness and caution which qualified him to excel in chess, and disciplined to rare perfection by a thorough mastery of the literature of the period, is still more strikingly shown in his papers in the *Athenæum* on "Unsuspected Corruptions of Shakespeare's Text," commenced in October 1872. These formed part of the materials intended to be made use of in an improved edition of Shakespeare's works which he proposed to prepare, but which for a variety of reasons was never published. In 1864 he published a facsimile of the Shakespeare folio of 1623, and a finely illustrated work entitled *Memorials of Shakespeare*. He was also the author of the *Great Schools of England*,—an *Account of the Foundation, Endowments, and Discipline of the Chief Seminaries of Learning in England*, 1865. An account of his career as a chess player, and a notice of his chief publications on the game, will be found under the heading *CHESS* (vol. i pp 601, 603). He died in London 22d June 1874.

STAVANGER, a seaport town of Norway, the administrative centre of an "amt" of the same name (population 114,164 in 1876), is situated on the west coast, on the south side of a beautiful fjord, about 127 miles north west of Christiansand. A railway to connect Stavanger with Christiania has been planned, but as yet only the terminal portions have been constructed, the Stavanger portion, which runs south to Ekersund for 47 miles, being opened in 1878. The town is for the most part a collection of narrow and irregular streets, but signs of the wealth acquired by its shipping trade and herring fishery appear in the well-built stone houses erected since the great fire of 1860. In 1884 314 vessels (70,006 tons) entered the harbour and 267 (57,479 tons) cleared. Though the bishop's see was removed from Stavanger to Christiansand in 1685, the old cathedral of St Swithun's, founded by the English bishop Reinald in the end of the 11th century, and rebuilt after being burned down in 1272, still remains, and, next to the cathedral of Trondhjem, is the most interesting piece of Gothic architecture in Norway. The old episcopal palace of Kongsgaard is now a Latin school. The communal hospital is an important institution. The town dates from the 8th or 9th century and became the seat of a bishopric in the 13th. In 1801 the population of

Stavanger was only 2500, by 1855 it was 12,000, and by 1875 20,350

STAVROPOL, a government of Northern Caucasasia, Russia, having an area of 26,530 square miles, and a population (rapidly increasing by Russian immigration) last returned at 637,893. It is bounded by Astrakhan and the province of the Don Cossacks on the N, Kubañ on the W, Terek on the S, and the Caspian Sea on the E, occupying the eastern part of the broad plains and steppes which fringe the main chain of CAUCASUS (qv) on the north. In the western part of the government a broad undulating swelling, ranging from 1500 to 2000 feet above sea level, extends northwards from the central mountain chain, in the southern part of this swelling, in the vicinity of Pyatigorsk, there is a group of sixteen mountains, 2800 to 4600 feet in height—the Beshtau,—which, as shown by Abich, ought to be considered as a porphyritic upheaval which took place at a point where the two predominant directions in Caucasus (south-west to north-east and south-east to north-west) meet. Northward and eastward of the above plateau are extensive steppes, from 400 to 200 feet above the sea, having gentle slopes both to the north (to the depression of the Manytch) and to the east (towards the low and dry steppes of the Caspian littoral). The geological structure of Stavropol is most interesting. The mountains in the southern parts of Pyatigorsk consist of trachytic porphyries and volcanic rocks. Numberless hot mineral springs (see PYATIGORSK) occur in this group, and earthquakes are most common in the region. A broad belt of Miocene deposits, represented by the "steppe limestone" with *Macta podolica*, girdles the hilly tracts, attaining a breadth of 40 miles or rather more, while the remainder of the steppes, which gently slope towards the Manytch and the Caspian, are occupied by the Post-Tertiary Caspian formation (loess).

Stavropol is chiefly watered by the Kuma and its tributaries (Podkumok, Karamyk, Burvola, &c.), its basin being the most fertile part of the province, but the evaporation is so great that the Kuma never reaches the Caspian except in spring. The Manytch is less a river than a series of lakes occupying a depression which formerly was a connecting channel between the Black Sea and the Caspian. This channel has two slopes, the eastern sometimes discharging its scanty water-supply into the Kuma, while on the western slope the elongated lakes which fill up the depression drain into the Don, reaching it, however, only during spring. Two Yegorlyks (Great and Middle), the Kalas, and the Tchogra (temporary tributaries of the Manytch) water the west part of Stavropol, while the Yeya and the Barsukly—a tributary of the Kubañ—rise in the district of Pyatigorsk. On the whole, irrigation is scanty, and in the eastern steppes water is supplied only by cisterns. Besides the few lakes of the Manytch depression, there are many smaller salt lakes around the Caspian. Timber is scarce, even in the hilly tracts.

The climate is severe. Although Stavropol and Pyatigorsk both have an average yearly temperature of 48° Fahr, frosts of -22° Fahr are not uncommon, and the average winter temperature is only 28° 7 at Stavropol (January, 25°, July, 71°). Yellow and other endemic fevers, sometimes very severe, are common on the low banks of the Kuma and Manytch.

The region is traversed by both the great highways along the western shore of the Caspian (the Vladikavkaz and the Derbent routes), and accordingly several nations in their migrations have left stragglers on the steppes of Stavropol. Thus we now find in these steppes Lamate Kalmucks (about 10,000), Mohammedan Turcomans and Nogais (together about 60,000), as well as less considerable remains of several other tribes. On the other

hand, immigrants from Great and Little Russia, Poles, Germans, Esthonians, Greeks, and even a few Scots (in a colony close to Pyatigorsk) have settled in the most fertile and best watered parts of Stavropol in the course of the present century. The Russian population is growing very rapidly, and already numbers upwards of 500,000.

There are three administrative districts, and the chief towns are Stavropol (35,470 inhabitants in 1884) and Alexandrovskaya (8710). There is also a territory of nomad natives which occupies more than two fifths of the entire area of the government.

The educational returns for 1883 show 7 gymnasiums and "real schools," with 1081 boys and 491 girls, and 139 elementary schools, with only 5310 boys and 1034 girls.

Agriculture is the chief occupation of the settled population, and so large is the harvest that no less than 16,000 labourers, attracted by high wages, come annually from European Russia to assist in gathering in the crops. Large amounts of corn are exported both to the mountainous districts of Caucasus and to Russia (Rostoff-on-the-Don). Cattle breeding is engaged in very largely, not only by the Kalmucks, Turcomans, and Nogais, but also by the Russians. In 1884 Stavropol had 151,000 horses, 808,500 cattle, 2,540,000 sheep, 45,000 goats, 75,000 pigs, and 7500 camels. Cattle and horses, as also wool, hair, hides, and sheepskins, are exported in considerable quantities. A remarkable feature of Stavropol is the rapid growth among the Russian peasant population of a great variety of domestic trades both for local supply and for exportation. Silk wares are now woven in the villages to such an extent as to become an important article of export to Russia. Many other petty trades have also grown up of late, such as various kinds of cotton-weaving, the manufacture of leather wares, small metallic wares, and so on. Manufactures proper (chiefly distillation) employed some 1000 persons in 1870, and their produce was estimated at about £140,000 per annum. Since that time they have slowly expanded. A brisk trade is carried on in the above mentioned articles of export, and twenty-nine village fairs show an aggregate annual return of nearly £300,000.

History—The northern slopes of Caucasus began to be colonized by Russians at a very early period, and as early as the 11th century part of the territory now occupied by Stavropol was known to Russian annalists as the Tmutarakani principality, which had Russian princes. A new attempt to colonize North Caucasus was made in the 16th century, under Ivan the Terrible, who married a Kabardian princess. This was again unsuccessful, and it was not till 1711 that Russia began regularly to colonize the territory by Cossack settlements. The military colonization was continued during the whole of last century, Kizlar was founded in 1736, Stavropol in 1776 or 1777. Immense tracts were given by Catherine II to her courtiers, who began to people them with serfs brought from Russia. The flow of immigrants rapidly increased as soon as peace was firmly established, and it is still on the increase, especially since the emancipation of the serfs, so that Stavropol is rapidly becoming a Russian province, with a comparatively limited number of natives in the steppes of its eastern part.

STAVROPOL, capital of the above province, is situated on a plateau 2000 feet above the sea, on the northern slope of the Caucasus, 360 miles to the north-west of Tiflis and 914 miles from Moscow. It is connected by rail with Rostoff-on-the-Don. Although founded only in 1776 for military purposes, it has rapidly grown, and has now a population of 35,500, while it is one of the best built provincial towns of the Russian empire. It has wide streets, and its houses are mostly of stone, large gardens surround the houses, and numerous farms and gardens occupy the territory (nearly 50,000 acres) belonging to the town. It is well provided with educational institutions, there being four gymnasia for boys and girls and several primary schools. Nearly all the manufactures of the province are concentrated in Stavropol. The trade is considerable, large numbers of cattle (more than 35,000 head annually) being sent to Moscow and St Petersburg, while tallow and more than 15,000 sheepskins are exported via Rostoff to Russia. Corn is also exported to the value of nearly £300,000, while manufactured wares are imported to the value of nearly £150,000. Armenian, Georgian, and Persian merchants carry on a lively trade in local wares.

STEAM-ENGINES AND OTHER HEAT-ENGINES

Definition of heat engines

1 A HEAT-ENGINE is a machine in which heat is employed to do mechanical work. In all practical heat-engines, work is done through the expansion by heat of a fluid which overcomes resistance as it expands—in steam engines by the expansion of water and water-vapour, in air-engines by the expansion of hot air, in gas engines by the expansion of a burnt mixture of air and gas. One of the most simple and historically one of the oldest types of heat-engines are guns, in which heat, generated by the combustion of an explosive, does work in giving energy of motion to a projectile. But guns differ so widely from all other types, both in their purpose and in their development, that it is convenient to leave them out of account in treating of engines which may serve as prime movers to other mechanism.

I EARLY HISTORY OF THE STEAM-ENGINE

Hero,
130 B.C.

2 The earliest notices of heat-engines are found in the *Pneumatica* of Hero of Alexandria (c 130 B.C.). Two contrivances described there deserve mention. One is the æolipile, a steam reaction-turbine consisting of a spherical vessel pivoted on a central axis and supplied with steam through one of the pivots. The steam escapes by bent pipes facing tangentially in opposite directions, at opposite ends of a diameter perpendicular to the axis. The globe revolves by reaction from the escaping steam, just as a Barker's mill is driven by escaping water. Another apparatus described by Hero (fig 1)¹ is interesting as the prototype of a class of engines which long afterwards became practically important.

A hollow altar containing air is heated by a fire kindled on it, the air in expanding drives some of the water contained in a spherical vessel beneath the altar into a bucket, which descends and opens the temple doors above by pulling round a pair of vertical posts to which the doors are fixed. When the fire is extinguished the air cools, the water leaves the bucket, and the doors close. In another device a jet of water driven out by expanding air is turned to account as a fountain.

3 From the time of Hero to the 17th century there is no progress to record, though here and there we find evidence that appliances like those described by Hero were used for trivial purposes, such as organ blowing and the turning of spits. The next distinct step was the publication in 1601 of a treatise on pneumatics by Giovanni Battista della Porta, in which he shows an apparatus similar to Hero's fountain, but with steam instead of air as the displacing fluid. Steam generated in a separate vessel passes into a closed chamber containing water, from which a pipe (open under the water) leads out. He also points out that the condensation of steam in the closed chamber may be used to produce a vacuum and suck up water from a lower level. In fact, his suggestions anticipate very fully the engine which a century later became in the hands of Savery the earliest commercially successful steam engine.

Della
Porta,
1601

FIG 1—Hero's Apparatus, 130 B.C.

In 1615 Solomon de Caus gives a plan of forcing up water by a steam fountain which differs from Della Porta's only in having one vessel serve both as boiler and as displacement-chamber, the hot water being itself raised.

4 Another line of invention was taken by Giovanni Branca (1629), who designed an engine shaped like a water-wheel, to be driven by the impact of a jet of steam on its vanes, and, in its turn, to drive other mechanism for various useful purposes. But Branca's suggestion was unproductive, and we find the course of invention revert to the line followed by Della Porta and De Caus.

5 The next contributor is one whose place is not easily assigned. To Edward Somerset, second marquis of Worcester, appears to be due the credit of making the first useful steam engine. Its object was to raise water, and it worked probably like Della Porta's model, but with a pair of displacement-chambers, from each of which alternately water was forced by steam from an independent boiler, or perhaps by applying heat to the chamber itself, while the other vessel was allowed to refill. Lord Worcester's description of the engine in his *Century of Inventions* (1663) is obscure, and no drawings are extant. It is therefore difficult to say whether there were any distinctly novel features except the double action, in particular it is not clear whether the suction of a vacuum was used to raise water as well as the direct pressure of steam. An engine of about two horse power was in use at Vauxhall in 1656, and the walls of Raglan Castle contain traces of another, but neither Worcester's efforts nor those of his widow were successful in securing the commercial success of his engine.

6 This success was reserved for Thomas Savery, who in 1698 obtained a patent for a water-raising engine, shown in fig 2. Steam is admitted to one of the oval vessels A, displacing water, which it drives up through the check-valve B. When the vessel A is emptied of water, the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel. This produces a vacuum and causes water to be sucked up through the pipe C and the valve D. Meanwhile, steam has been displacing water from the other vessel, and is ready to be condensed there. The valves B and D open only upwards. The supplementary boiler and furnace E are for feeding water to the main boiler, E is filled while cold and a fire is lighted under it, it then acts like the vessel of De Caus in forcing a supply of feed water into the main boiler F. The gauge cocks G, G are an interesting feature of detail. Another form of Savery's engine had only one displacement-chamber and worked intermittently. In the use of artificial means to condense the steam, and in the application

Stavanger was only 2500, by 1855 it was 12,000, and by 1875 20,350

STAVROPOL, a government of Northern Caucasus, Russia, having an area of 26,530 square miles, and a population (rapidly increasing by Russian immigration) last returned at 637,893. It is bounded by Astrakhan and the province of the Don Cossacks on the N, Kubañ on the W, Terek on the S, and the Caspian Sea on the E., occupying the eastern part of the broad plains and steppes which fringe the main chain of CAUCASUS (*qv*) on the north. In the western part of the government a broad undulating swelling, ranging from 1500 to 2000 feet above sea level, extends northwards from the central mountain chain, in the southern part of this swelling, in the vicinity of Pyatigorsk, there is a group of sixteen mountains, 2800 to 4600 feet in height—the Beshtau,—which, as shown by Abich, ought to be considered as a porphyritic upheaval which took place at a point where the two predominant directions in Caucasus (south west to north-east and south-east to north-west) meet. Northward and eastward of the above plateau are extensive steppes, from 400 to 200 feet above the sea, having gentle slopes both to the north (to the depression of the Manytch) and to the east (towards the low and dry steppes of the Caspian littoral). The geological structure of Stavropol is most interesting. The mountains in the southern parts of Pyatigorsk consist of trachytic porphyries and volcanic rocks. Numberless hot mineral springs (see PYATIGORSK) occur in this group, and earthquakes are most common in the region. A broad belt of Miocene deposits, represented by the "steppe limestone" with *Mastra podolica*, girdles the hilly tracts, attaining a breadth of 40 miles or rather more, while the remainder of the steppes, which gently slope towards the Manytch and the Caspian, are occupied by the Post-Tertiary Caspian formation (loess).

Stavropol is chiefly watered by the Kuma and its tributaries (Podkumok, Karamyk, Buivola, &c.), its basin being the most fertile part of the province, but the evaporation is so great that the Kuma never reaches the Caspian except in spring. The Manytch is less a river than a series of lakes occupying a depression which formerly was a connecting channel between the Black Sea and the Caspian. This channel has two slopes, the eastern sometimes discharging its scanty water supply into the Kuma, while on the western slope the elongated lakes which fill up the depression drain into the Don, reaching it, however, only during spring. Two Yegorlyks (Great and Middle), the Kalais, and the Tehogra (temporary tributaries of the Manytch) water the west part of Stavropol, while the Yeya and the Barsnkly—a tributary of the Kubañ—rise in the district of Pyatigorsk. On the whole, irrigation is scanty, and in the eastern steppes water is supplied only by cisterns. Besides the few lakes of the Manytch depression, there are many smaller salt lakes around the Caspian. Timber is scarce, even in the hilly tracts.

The climate is severe. Although Stavropol and Pyatigorsk both have an average yearly temperature of 48° Fahr, frosts of -22° Fahr are not uncommon, and the average winter temperature is only 28° 7 at Stavropol (January, 25°, July, 71°). Yellow and other endemic fevers, sometimes very severe, are common on the low banks of the Kuma and Manytch.

The region is traversed by both the great highways along the western shore of the Caspian (the Vladikavkaz and the Derbent routes), and accordingly several nations in their migrations have left stragglers on the steppes of Stavropol. Thus we now find in these steppes Lamaite Kalmucks (about 10,000), Mohammedan Turcomans and Nogais (together about 60,000), as well as less considerable remains of several other tribes. On the other

hand, immigrants from Great and Little Russia, Poles, Germans, Esthomans, Greeks, and even a few Scots (in a colony close to Pyatigorsk) have settled in the most fertile and best watered parts of Stavropol in the course of the present century. The Russian population is growing very rapidly, and already numbers upwards of 500,000.

There are three administrative districts, and the chief towns are Stavropol (35,470 inhabitants in 1884) and Alexandrovskaya (8710). There is also a territory of nomad natives which occupies more than two fifths of the entire area of the government.

The educational returns for 1883 show 7 gymnasiums and "real schools," with 1081 boys and 491 girls, and 139 elementary schools, with only 5310 boys and 1034 girls.

Agriculture is the chief occupation of the settled population, and so large is the harvest that no less than 16,000 labourers, attracted by high wages, come annually from European Russia to assist in gathering in the crops. Large amounts of corn are exported both to the mountainous districts of Caucasus and to Russia (Rostoff-on-the-Don). Cattle breeding is engaged in very largely, not only by the Kalmucks, Turcomans, and Nogais, but also by the Russians. In 1884 Stavropol had 154,000 horses, 808,500 cattle, 2,540,000 sheep, 45,000 goats, 75,000 pigs, and 7500 camels. Cattle and horses, as also wool, hair, hides, and sheepskins, are exported in considerable quantities. A remarkable feature of Stavropol is the rapid growth among the Russian peasant population of a great variety of domestic trades both for local supply and for exportation. Silk wares are now woven in the villages to such an extent as to become an important article of export to Russia. Many other petty trades have also grown up of late, such as various kinds of cotton weaving, the manufacture of leather wares, small metallic wares, and so on. Manufactures proper (chiefly distillation) employed some 1000 persons in 1870, and their produce was estimated at about £140,000 per annum. Since that time they have slowly expanded. A brisk trade is carried on in the above mentioned articles of export, and twenty nine village fairs show an aggregate annual return of nearly £300,000.

History—The northern slopes of Caucasus began to be colonized by Russians at a very early period, and as early as the 11th century part of the territory now occupied by Stavropol was known to Russian annals as the Tmutarakañ principality, which had Russian princes. A new attempt to colonize North Caucasus was made in the 16th century, under Ivan the Terrible, who married a Kabardian princess. This was again unsuccessful, and it was not till 1711 that Russia began regularly to colonize the territory by Cossack settlements. The military colonization was continued during the whole of last century, Kizlar was founded in 1736, Stavropol in 1776 or 1777. Immense tracts were given by Catherine II to her courtiers, who began to people them with serfs brought from Russia. The flow of immigrants rapidly increased as soon as peace was firmly established, and it is still on the increase, especially since the emancipation of the serfs, so that Stavropol is rapidly becoming a Russian province, with a comparatively limited number of natives in the steppes of its eastern part.

STAVROPOL, capital of the above province, is situated on a plateau 2000 feet above the sea, on the northern slope of the Caucasus, 360 miles to the north-west of Tiflis and 914 miles from Moscow. It is connected by rail with Rostoff-on-the-Don. Although founded only in 1776 for military purposes, it has rapidly grown, and has now a population of 35,500, while it is one of the best built provincial towns of the Russian empire. It has wide streets, and its houses are mostly of stone, large gardens surround the houses, and numerous farms and gardens occupy the territory (nearly 50,000 acres) belonging to the town. It is well provided with educational institutions, there being four gymnasia for boys and girls and several primary schools. Nearly all the manufactures of the province are concentrated in Stavropol. The trade is considerable, large numbers of cattle (more than 35,000 head annually) being sent to Moscow and St Petersburg, while tallow and more than 15,000 sheepskins are exported *via Rostoff to Russia*. Corn is also exported to the value of nearly £300,000, while manufactured wares are imported to the value of nearly £150,000. Armenian, Georgian, and Persian merchants carry on a lively trade in local wares.

STEAM-ENGINES AND OTHER HEAT-ENGINES

Defini-
tion of
heat
engines

1 A HEAT ENGINE is a machine in which heat is employed to do mechanical work. In all practical heat-engines, work is done through the expansion by heat of a fluid which overcomes resistance as it expands—in steam-engines by the expansion of water and water-vapour, in air-engines by the expansion of hot air, in gas engines by the expansion of a burnt mixture of air and gas. One of the most simple and historically one of the oldest types of heat-engines are guns, in which heat, generated by the combustion of an explosive, does work in giving energy of motion to a projectile. But guns differ so widely from all other types, both in their purpose and in their development, that it is convenient to leave them out of account in treating of engines which may serve as prime movers to other mechanism.

I EARLY HISTORY OF THE STEAM-ENGINE

Hero,
130 B.C.

2 The earliest notices of heat-engines are found in the *Pneumatica* of Hero of Alexandria (c. 130 B.C.). Two contrivances described there deserve mention. One is the æolipile, a steam reaction turbine consisting of a spherical vessel pivoted on a central axis and supplied with steam through one of the pivots. The steam escapes by bent pipes facing tangentially in opposite directions, at opposite ends of a diameter perpendicular to the axis. The globe revolves by reaction from the escaping steam, just as a Barker's mill is driven by escaping water. Another apparatus described by Hero (fig. 1)¹ is interesting as the prototype of a class of engines which long afterwards became practically important. A hollow altar containing air is heated by a fire kindled on it, the air in expanding drives some of the water contained in a spherical vessel beneath the altar into a bucket, which descends and opens the temple doors above by pulling round a pair of vertical posts to which the doors are fixed. When the fire is

FIG 1—Hero's Apparatus, 130 B.C.

extinguished the air cools, the water leaves the bucket, and the doors close. In another device a jet of water driven out by expanding air is turned to account as a fountain.

3 From the time of Hero to the 17th century there is no progress to record, though here and there we find evidence that appliances like those described by Hero were used for trivial purposes, such as organ-blowing and the turning of spits. The next distinct step was the publication in 1601 of a treatise on pneumatics by Giovanni Battista della Porta, in which he shows an apparatus similar to Hero's fountain, but with steam instead of air as the displacing fluid. Steam generated in a separate vessel passes into a closed chamber containing water, from which a pipe (open under the water) leads out. He also points out that the condensation of steam in the closed vessel may be used to produce a vacuum and suck up water from a lower level. In fact, his suggestions anticipate very fully the engine which a century later became in the hands of Savery the earliest commercially successful steam engine.

Della
Porta,
1601

In 1615 Solomon de Caus gives a plan of forcing up water by a steam fountain which differs from Della Porta's only in having one vessel serve both as boiler and as displacement-chamber, the hot water being itself raised.

4 Another line of invention was taken by Giovanni Branca (1629), who designed an engine shaped like a water-wheel, to be driven by the impact of a jet of steam on its vanes, and, in its turn, to drive other mechanism for various useful purposes. But Branca's suggestion was unproductive, and we find the course of invention revert to the line followed by Della Porta and De Caus.

5 The next contributor is one whose place is not easily assigned. To Edward Somerset, second marquis of Worcester, appears to be due the credit of making the first useful steam engine. Its object was to raise water, and it worked probably like Della Porta's model, but with a pair of displacement-chambers, from each of which alternately water was forced by steam from an independent boiler, or perhaps by applying heat to the chamber itself, while the other vessel was allowed to refill. Lord Worcester's description of the engine in his *Century of Inventions* (1663) is obscure, and no drawings are extant. It is therefore difficult to say whether there were any distinctly novel features except the double action, in particular it is not clear whether the suction of a vacuum was used to raise water as well as the direct pressure of steam. An engine of about two horse power was in use at Vauxhall in 1656, and the walls of Raglan Castle contain traces of another, but neither Worcester's efforts nor those of his widow were successful in securing the commercial success of his engine.

6 This success was reserved for Thomas Savery, who in 1698 obtained a patent for a water-raising engine, shown in fig. 2. Steam is admitted to one of the oval vessels A, displacing water, which it drives up through the check-valve B. When the vessel A is emptied of water, the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel. This produces a vacuum and causes water to be sucked up through the pipe C and the valve D. Meanwhile, steam has been displacing water from the other vessel, and is ready to be condensed there. The valves B and D open only upwards. The supplementary boiler and furnace E are for feeding water to the main boiler, E is filled while cold and a fire is lighted under it, it then acts like the vessel of De Caus in forcing a supply of feed water into the main boiler F. The gauge cocks G, G are an interesting feature of detail. Another form of Savery's engine had only one displacement-chamber and worked intermittently. In the use of artificial means to condense the steam, and in the application

FIG 2—Savery's Pumping Engine, 1698

XXII — 60

¹ From Greenwood's translation of Hero's *Pneumatica*

of the vacuum so formed to raise water by suction from a level lower than that of the engine, Savery's engine was probably an improvement on Worcester's, in any case it found what Worcester's engine had failed to find,—considerable employment in pumping mines and in raising water to supply houses and towns, and even to drive water-wheels. A serious difficulty which prevented its general use in mines was the fact that the height through which it would lift water was limited by the pressure the boiler and vessels could bear. Pressures as high as 8 or 10 atmospheres were employed—and that, too, without a safety valve—but Savery found it no easy matter to deal with high pressure steam, he complains that it melted his common solder, and forced him, as Desaguliers tells us, "to be at the pains and charge to have all us joints soldered with spelter." Apart from this drawback the waste of fuel was enormous, from the condensation of steam which took place on the surface of the water and on the sides of the displacement-chamber at each stroke, the consumption of coal, was, in proportion to the work done, some twenty times greater than in a good modern steam-engine. In a tract called *The Miner's Friend*, Savery alludes thus to the alternate heating and cooling of the water vessel: "On the outside of the vessel you may see how the water goes out as well as if the vessel were transparent, for so far as the steam continues within the vessel so far is the vessel dry without, and so very hot as scarce to endure the least touch of the hand. But as far as the water is, the said vessel will be cold and wet where any water has fallen on it, which cold and moisture vanishes as fast as the steam in its descent takes place of the water." Before Savery's engine was entirely displaced by its successor, Newcomen's, it was improved by Desaguliers, who applied to it the safety valve (invented by Papin), and substituted condensation by a jet of cold water within the vessel for the surface condensation used by Savery.

cylinder
in
stone
mine.

7 So early as 1678 the use of a piston and cylinder (long before known as applied to pumps) in a heat-engine had been suggested by Jean Heautefeuille, who proposed to use the explosion of gunpowder either to raise a piston or to force up water, or to produce, by the subsequent cooling of the gases, a partial vacuum into which water might be sucked up. Two years later Huygens described an engine in which the explosion of gunpowder in a cylinder expelled part of the gaseous contents, after which the cooling of the remainder caused a piston to descend under atmospheric pressure, and the piston in descending did work by raising a weight.

papin

8 In 1690 Denis Papin, who ten years before had invented the safety-valve as an adjunct to his "digester," suggested that the condensation of steam should be employed to make a vacuum under a piston previously raised by the expansion of the steam. Papin's was the earliest cylinder and piston steam engine, and his plan of using steam was that which afterwards took practical shape in the atmospheric engine of Newcomen. But

Fig 3—Papin, 1705.

his scheme was made unworkable by the fact that he proposed to use but one vessel as both boiler and cylinder

A small quantity of water was placed at the bottom of a cylinder and heat was applied. When the piston had risen the fire was removed, the steam was allowed to cool, and the piston did work in its down-stroke under the pressure of the atmosphere. After hearing of Savery's engine in 1705 Papin turned his attention to improving it, and devised a modified form, shown in fig 3, in which the displacement-chamber A was a cylinder, with a floating diaphragm or piston on the top of the water to keep the water and steam from direct contact with one another. The water was delivered into a closed air vessel B, from which it issued in a continuous stream against the vanes of a water-wheel. After the steam had done its work in the displacement-chamber it was allowed to escape by the stop-cock C instead of being condensed. Papin's engine was in fact a non-condensing single acting steam-pump, with steam cylinder and pump-cylinder in one. A curious feature of it was the heater D, a hot mass of metal placed in the diaphragm for the purpose of keeping the steam dry. Among the many inventions of Papin was a boiler with an internal fire box,—the earliest example of a construction that is now almost universal.¹

9 While Papin was thus going back from his first Newcomen's notion of a piston engine to Savery's cruder type, a new inventor had appeared who made the piston engine a practical success by separating the boiler from the cylinder and by using (as Savery had done) artificial means to condense the steam. This was Newcomen, who in 1705, with his assistant Cawley, gave the steam engine the form shown in fig 4. Steam admitted from the boiler to the cylinder allowed the piston to be raised by a heavy counterpoise on the other side of the beam.

Then the steam-valve was shut and a jet of cold water entered the cylinder and condensed the steam. The piston was consequently forced down by the pressure of the atmosphere and did work on the pump. The next entry of steam expelled the condensed water from the cylinder through an escape valve.

Fig 4—Newcomen's Atmospheric Engine, 1705

The piston was kept tight by a layer of water on its upper surface. Condensation was at first effected by cooling the outside of the cylinder, but the accidental leakage of the packing water past the piston showed the advantage of condensing by a jet of injection water, and this plan took the place of surface condensation. The engine used steam whose pressure was little if at all greater than that of the atmosphere, sometimes indeed it was worked with the manhole lid off the boiler.

10 About 1711 Newcomen's engine began to be introduced for pumping mines, and in 1713 a boy named Humphrey Potter, whose duty it was to open and shut the valves of an engine he attended, made the engine self-acting by causing the beam itself to open and close the valves by suitable cords and catches. Potter's rude device was simplified in 1718 by Henry Beighton, who suspended from the beam a rod called the plug-tree, which worked the valves by means of tappets. By 1725 the engine was in common use in collieries, and it held its place without material change for about three-quarters of a century in

¹ For an account of Papin's inventions, see his *Life and Letters*, by Dr E. Gerland, Berlin, 1881.

all Near the close of its career the atmospheric engine was much improved in its mechanical details by Smeaton, who built many large engines of this type about the year 1770, just after the great step which was to make Newcomen's engine obsolete had been taken by James Watt

Compared with Savery's engine, Newcomen's had (as a pumping-engine) the great advantage that the intensity of pressure in the pumps was not in any way limited by the pressure of the steam. It shared with Savery's, in a scarcely less degree, the defect already pointed out, that steam was wasted by the alternate heating and cooling of the vessel into which it was led. Though obviously capable of more extended uses, it was in fact almost exclusively employed to raise water,—in some instances for the purpose of turning water-wheels to drive other machinery. Even contemporary writers complain of its "vast consumption of fuel," which appears to have been scarcely smaller than that of the engine of Savery.

Watt,
1763

11 In 1763 James Watt, an instrument maker in Glasgow, while engaged by the university in repairing a model of Newcomen's engine, was struck with the waste of steam to which the alternate chilling and heating of the cylinder gave rise. He saw that the remedy, in his own words, would lie in keeping the cylinder as hot as the steam that entered it. With this view he added to the engine a new organ—an empty vessel separate from the cylinder, into which the steam should be allowed to escape from the cylinder, to be condensed there by the application of cold water either outside or as a jet. To preserve the vacuum in his condenser he added a pump called the air-pump, whose function was to pump from it the condensed steam and water of condensation, as well as the air which would otherwise accumulate by leakage or by being brought in with the steam or with the injection water. Then as the cylinder was no longer used as a condenser he was able to keep it hot by clothing it with non-conducting bodies, and in particular by the use of a *steam-jacket*, or layer of hot steam between the cylinder and an external casing. Further, and still with the same object, he covered in the top of the cylinder, taking the piston rod out through a steam-tight stuffing box, and allowed steam instead of air to press upon the piston's upper surface. The idea of using a separate condenser had no sooner occurred to Watt than he put it to the test by constructing the apparatus shown in fig 5. There A is the cylinder, B a surface condenser, and C the air-pump. The cylinder was filled with steam above the piston, and a vacuum was formed in the surface condenser B. On opening the stop-cock D the steam rushed over from the cylinder and was condensed, while the piston rose and lifted a weight. After several trials Watt patented his improvements in 1769, they are described in his specification in the following words, which, apart from their immense historical interest, deserve careful study as a statement of principles which to this day guide the scientific development of the steam engine—

FIG 5—Watt's Experimental Apparatus

Watt's
specification,
1769

"My method of lessening the consumption of steam, and consequently fuel, in fire engines, consists of the following principles—
"First, That vessel in which the powers of steam are to be employed to work the engine, which is called the cylinder in common fire engines, and which I call the steam vessel, must, during the whole time the engine is at work, be kept as hot as the steam that enters it, first by enclosing it in a case of wood, or any other materials that transmit heat slowly, secondly, by surrounding it with steam or other heated bodies, and, thirdly, by suffering neither water nor any other substance colder than the steam to enter or touch it during that time

"Secondly, In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensed in vessels distinct from the steam vessels or cylinders, although occasionally communicating with them, these vessels I call condensers, and, whilst the engines are working, these condensers ought at least to be kept as cold as the air in the neighbourhood of the engines, by application of water or other cold bodies

"Thirdly, Whatever air or other elastic vapour is not condensed by the cold of the condenser, and may impede the working of the engine, is to be drawn out of the steam vessels or condensers by means of pumps, wrought by the engines themselves, or otherwise

"Fourthly, I intend in many cases to employ the expansive force of steam to press on the pistons, or whatever may be used instead of them, in the same manner in which the pressure of the atmosphere is now employed in common fire engines. In cases where cold water cannot be had in plenty, the engines may be wrought by this force of steam only, by discharging the steam into the air after it has done its office

"Fifthly, I intend in some cases to apply a degree of cold not capable of reducing the steam to water, but of contracting it considerably, so that the engines shall be worked by the alternate expansion and contraction of the steam

"Lastly, Instead of using water to render the pistons and other parts of the engine air and steam tight, I employ oils, waxes, resinous bodies, fat of animals, quicksilver and other metals in their fluid state"

The fifth claim was for a rotary engine, and need not be quoted here

The "common fire engine" alluded to was the steam-engine, or, as it was more generally called, the "atmospheric" engine of Newcomen. Enormously important as Watt's first patent was, it resulted for a time in the production of nothing more than a greatly improved engine of the Newcomen type, much less wasteful of fuel, able to make faster strokes, but still only suitable for pumping, still single acting, with steam admitted during the whole stroke, the piston, as before, pulling the beam by a chain working on a circular arc. The condenser was generally worked by injection, but Watt has left a model of a surface condenser made up of small tubes, in every essential respect like the condensers now used in marine engines

12 Fig 6 is an example of the Watt pumping engine of this period. It should be noticed that, although the top of the cylinder is closed and steam has access to the upper side of the piston, this is done only to keep the cylinder and piston warm. The engine is still single-acting, the steam in the upper side merely plays the part which was played in Newcomen's engine by the atmosphere, and it is the lower end of the cylinder alone that is ever put in communication with the condenser.

There are three valves,—the "steam" valve *a*, the "equilibrium" valve *b*, and the "exhaust" valve *c*. At the beginning of the down stroke *c* is opened to produce a vacuum below the piston and *a* is

FIG 6—Watt's Single-Acting Engine, 1769

opened to produce a vacuum below the piston and *a* is

opened to admit steam above it. At the end of the down-stroke *a* and *c* are shut and *b* is opened. This puts the two sides in equilibrium, and allows the piston to be pulled up by the pump-rod *P*, which is heavy enough to serve as a counterpoise. *C* is the condenser, and *A* the air-pump, which discharges into the hot well *H*, whence the supply of the feed-pump *F* is drawn.

13 In a second patent (1781) Watt describes the "sun-and-planet" wheels and other methods of making the engine give continuous revolving motion to a shaft provided with a fly wheel. He had invented the crank and connecting rod for this purpose, but it had meanwhile been patented by one Pickard, and Watt, rather than make terms with Pickard, whom he regarded as a plagiarist of his own ideas, made use of his sun-and-planet motion until the patent on the crank expired. The reciprocating motion of earlier forms had served only for pumping, by this invention Watt opened up for the steam-engine a thousand other channels of usefulness. The engine was still single acting, the connecting rod was attached to the far end of the beam, and that carried a counterpoise which served to raise the piston when steam was admitted below it.

14 In 1782 Watt patented two further improvements of the first importance, both of which he had invented some years before. One was the use of double action, that is to say, the application of steam and vacuum to each side of the piston alternately. The other (invented as early as 1769) was the use of steam expansively, in other words the plan (now used in all engines that aim at economy of fuel) of stopping the admission of steam when the piston had made only a part of its stroke, and allowing the rest of the stroke to be performed by the expansion of the steam already in the cylinder. To let the piston push as well as pull the end of the beam Watt devised his so-called parallel motion, an arrangement of links connecting the piston rod head with the beam in

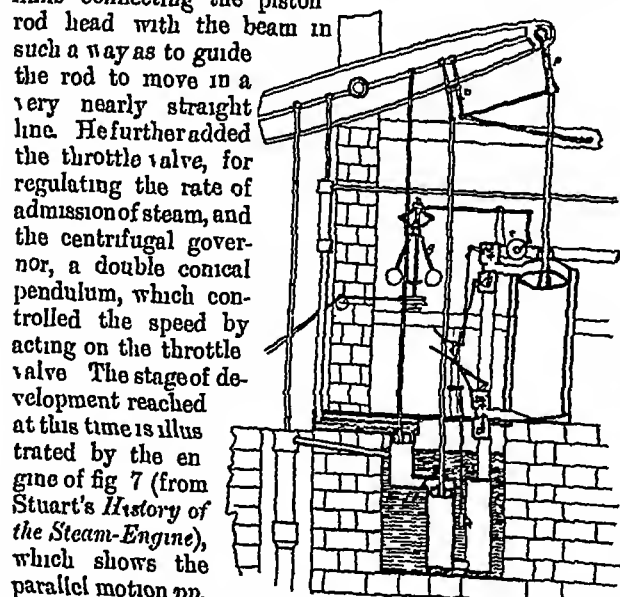

Fig 7 - Watt's Double Acting Engine, 1782.

such a way as to guide the rod to move in a very nearly straight line. He further added the throttle valve, for regulating the rate of admission of steam, and the centrifugal governor, a double conical pendulum, which controlled the speed by acting on the throttle valve. The stage of development reached at this time is illustrated by the engine of fig 7 (from Stuart's *History of the Steam-Engine*), which shows the parallel motion *pp*, the governor *g*, the throttle-valve *t*, and a pair of steam and exhaust valves at each end of the cylinder. Among other inventions of Watt were the "indicator," by which diagrams showing the relation of the steam pressure in the cylinder to the movement of the piston are automatically drawn, a steam tilt-hammer, and also a steam locomotive for ordinary roads,—but this invention was not prosecuted.

In partnership with Matthew Boulton, Watt carried on in Birmingham the manufacture and sale of his engines with the utmost success, and held the field against all

rivals in spite of severe assaults on the validity of his patents. Notwithstanding his accurate knowledge of the advantage to be gained by using steam expansively he continued to employ only low pressures—seldom more than 7 lb per square inch over that of the atmosphere. His boilers were fed, as Newcomen's had been, through an open pipe which rose high enough to let the column of water in it balance the pressure of the steam. He introduced the term "horse power" as a mode of rating engines, defining one horse power as the rate at which work is done when 33,000 lb are raised one foot in one minute. This estimate was based on trials of the work done by horses, it is excessive as a statement of what an average horse can do, but Watt purposely made it so in order that his customers might have no reason to complain on this score.

15 In the fourth claim in Watt's first patent, the second sentence describes a non condensing engine, which would have required steam of a higher pressure. This, however, was a line of invention which Watt did not follow up, perhaps because so early as 1725 a non condensing engine had been described by Leupold in his *Theatrum Machinarum*. Leupold's proposed engine is shown in fig 8, which makes its action sufficiently clear.

Watt's aversion to high-pressure steam was strong, and its influence on steam-engine practice long survived the expiry of his patents. So much indeed was this the case that the terms "high-pressure" and "non-condensing" were for many years synonymous, in contradistinction to the "low-pressure" or condensing engines of Watt. This nomenclature no longer holds, in modern practice many condensing engines use as high pressures as non-condensing engines, and by doing so are able to take advantage of Watt's great invention of expansive working to a degree which was impossible in his own practice.

Fig 8 - Leupold's Non Condensing Engine, 1725.

16 The introduction of the non condensing and, at that time, relatively high-pressure engine, was effected in England by Trevithick and in America by Oliver Evans about 1800. Both Evans and Trevithick applied their engines to propel carriages on roads, and both used for a boiler a cylindrical vessel with a cylindrical flue inside—the construction now known as the Cornish boiler. In partnership with Bull, Trevithick had previously made direct-acting pumping-engines, with an inverted cylinder set over and in line with the pump rod, thus dispensing with the beam that had been a feature in all earlier forms. But in these "Bull" engines, as they were called, a condenser was used, or, rather, the steam was condensed by a jet of cold water in the exhaust-pipe, and Boulton and Watt successfully opposed them as infringing Watt's patents. To Trevithick belongs the distinguished honour of being the first to use a steam carriage on a railway, in 1804 he built a locomotive in the modern sense, to run on what had formerly been a horse tramway in Wales, and it is noteworthy that the exhaust steam was discharged into the funnel to force the furnace draught, a device which, 25 years later, in the hands of George Stephenson, went far to make the locomotive what it is to-day. In this connection it may be added that as early as 1769 a steam-

Cugnot, 1769, carriage for roads had been built by Cugnot in France, who used a pair of single acting high-pressure cylinders to turn a driving axle step by step by means of pawls and ratchet-wheels. To the initiative of Evans may be ascribed the early general use of high pressure steam in the United States, a feature which for many years distinguished American from English practice.

Compound engine Hornblower, 1781. 17 Amongst the contemporaries of Watt one name deserves special mention. In 1781 Jonathan Hornblower constructed and patented what would now be called a compound engine, with two cylinders of different sizes. Steam was first admitted into the smaller cylinder, and then passed over into the larger, doing work against a piston in each. In Hornblower's engine the two cylinders were placed side by side, and both pistons worked on the same end of a beam overhead. This was an instance of the use of steam expansively, and as such was earlier than the patent, though not earlier than the invention, of expansive working by Watt. Hornblower was crushed by the Birmingham firm for infringing their patent in the use of a separate condenser and air-pump. The compound engine

Woolf, 1804, was revived in 1801 by Woolf, with whose name it is often associated. Using steam of fairly high pressure, and cutting off the supply before the end of the stroke in the small cylinder, Woolf expanded the steam to several times its original volume. Mechanically the double-cylinder compound engine has this advantage over an engine in which the same amount of expansion is performed in a single cylinder, that the sum of the forces exerted by the two pistons in the compound engine varies less throughout the action than the force exerted by the piston of the single cylinder engine. This advantage may have been clear to Hornblower and Woolf, and to other early users of compound expansion. But another and probably a more important merit of the system lies in a fact of which neither they nor for many years their followers in the use of compound engines were aware—the fact that by dividing the whole range of expansion into two parts the cylinders in which these are separately performed are subject to a reduced range of fluctuation in their temperature. This, as will be afterwards pointed out, limits to a great extent a source of waste which is present in all steam engines, the waste which results from the heating and cooling of the metal by its alternate contact with hot and cooler steam. The system of compound expansion is now used in nearly all large engines that pretend to economy. Its introduction forms the only great improvement which the steam engine has undergone since the time of Watt, and we are able to recognize it as a very important step in the direction set forth in his "first principle," that the cylinder should be kept as hot as the steam that enters it.

Cornish engine. 18 Woolf introduced the compound engine somewhat widely about 1814, as a pumping engine in the mines of Cornwall. But here it met a strong competitor in the high-pressure single-cylinder engine of Trevithick, which had the advantage of greater simplicity in construction. Woolf's engine fell into comparative disuse, and the single-cylinder type took a form which, under the name of the Cornish pumping engine, was for many years famous for its great economy of fuel. In this engine the cylinder was set under one end of a beam, from the other end of which hung a heavy rod which operated a pump at the foot of the shaft. Steam was admitted above the piston for a short portion of the stroke, thereby raising the pump-rod, and was allowed to expand for the remainder. Then an equilibrium valve, connecting the space above and below the piston, as in fig 6, was opened, and the pump-rod descended, doing work in the pump and raising the engine piston. The large mass which had to be started

and stopped at each stroke served by its inertia to counter-balance the unequal pressure of the steam, for the ascending rods stored up energy of motion in the early part of the stroke, when the steam pressure was greatest, and gave out energy in the later part, when expansion had greatly lowered the pressure. The frequency of the stroke was controlled by a device called a cataract, consisting of a small plunger pump, in which the plunger, raised at each stroke by the engine, was allowed to descend more or less slowly by the escape of fluid below it through an adjustable orifice, and in its descent liberated catches which held the steam and exhaust valves from opening. A similar device controlled the equilibrium valve, and could be set to give a pause at the end of the piston's down stroke, so that the pump cylinder might have time to become completely filled. The Cornish engine is interesting as the earliest form which achieved an efficiency comparable with that of good modern engines. For many years monthly reports were published of the "duty" of these engines, the "duty" being the number of foot-pounds of work done per bushel or (in some cases) per cwt of coal. The average duty of engines in the Cornwall district rose from about 18 millions of foot-pounds per cwt of coal in 1813 to 68 millions in 1844, after which less effort seems to have been made to maintain a high efficiency.¹ In individual cases much higher results were reported, as in the Fowey Consols engine, which in 1835 was stated to have a duty of 125 millions. This (to use a more modern mode of reckoning) is equivalent to the consumption of only a little more than 1½ lb of coal per horse power per hour—a result surpassed by very few engines in even the best recent practice. It is difficult to credit figures which, even in exceptional instances, place the Cornish engine of that period on a level with the most efficient modern engines—in which compound expansion and higher pressure combine to make a much more perfect thermodynamic machine, and apart from this there is room to question the accuracy of the Cornish reports. They played, however, a useful part in the process of steam engine development by directing attention to the question of efficiency, and by demonstrating the advantage to be gained by high pressure and expansive working, at a time when the theory of the steam engine had not yet taken shape.

19 The final revival of the compound engine did not occur until about the middle of the century, and then several agencies combined to effect it. In 1845 M'Naught introduced a plan of improving beam engines of the original Watt type, by adding a high pressure cylinder whose piston acted on the beam between the centre and the fly-wheel end. Steam of higher pressure than had formerly been used, after doing work in the low cylinder, passed into the old or low-pressure cylinder, where it was further expanded. Many engines whose power was proving insufficient for the extended machinery they had to drive were "M'Naughted" in this way, and after conversion were found not only to yield more power but to show a marked economy of fuel. The compound form was selected by Mr Pole for the pumping engines of Lambeth and other waterworks about 1850, in 1854 John Elder began to use it in marine engines, in 1857 Mr Cowper added a steam jacketed intermediate reservoir for steam between the high and low pressure cylinders, which made it unnecessary for the low pressure piston to be just beginning when the other piston was just ending its stroke. As facilities increased for the use of high pressure steam, compound expansion became more and more general, its advantage becoming more conspicuous with every

¹ *Min Proc Inst C E*, vol xxiii, 1863

increase in boiler pressure—until now there are few large land engines and scarcely any marine engines that do not employ it. In marine practice, where economy of fuel is a much more important factor in determining the design than it is on land, the principle of compound expansion has lately been greatly extended by the introduction of triple and even quadruple expansion engines, in which the steam is made to expand successively in three or in four cylinders. Even in the building of locomotive engines, where other considerations are of more moment than the saving of coal, the system of compound expansion is beginning to find a place.

The growth of compound expansion has been referred to at some length, because it forms the most distinctive improvement which the steam-engine has undergone since the time of Watt. For the rest, the progress of the steam-engine has consisted in its adaptation to particular uses, in the invention of features of mechanical detail, in the recognition and application of thermodynamical principles, and in improved methods of engineering construction by which it has profited in common with all other machines. These have in particular made possible the use of steam of eight or ten times the pressure of that employed by Watt.

motives.

20 The adaptation of the steam engine to railways, begun by Trevithick, became a success in the hands of George Stephenson, whose engine the "Rocket," when tried along with others on the Stockton and Darlington road in 1829, not only distanced its competitors but settled once and for all the question whether horse traction or steam traction was to be used on railways. The principal features of the "Rocket" were an improved steam-blast for urging the combustion of coal and a boiler (suggested by Booth, the secretary of the railway) in which a large heating surface was given by the use of many small tubes through which the hot gases passed. Further, the cylinders, instead of being vertical as in earlier locomotives, were set in at a slope, which was afterwards altered to a position more nearly horizontal. To these features there was added later the "link motion," a contrivance which enabled the engine to be easily reversed and the amount of expansion to be readily varied. In the hands of George Stephenson and his son Robert the locomotive took a form which has been in all essentials maintained by the far heavier locomotives of to-day.

boats.

21 The first practical steamboat was the tug "Charlotte Dundas," built by William Symmington, and tried in the Forth and Clyde Canal in 1802. A Watt double-acting condensing engine, placed horizontally, acted directly by a connecting rod on the crank of a shaft at the stern, which carried a revolving paddle wheel. The trial was successful, but steam towing was abandoned for fear of injuring the banks of the canal. Ten years later Henry Bell built the "Comet," with side paddle wheels, which ran as a passenger steamer on the Clyde, but an earlier inventor to follow up Symmington's success was the American Robert Fulton, who, after unsuccessful experiments on the Seine, fitted a steamer on the Hudson in 1807 with engines made to his designs by Boulton and Watt, and brought steam navigation for the first time to commercial success.

use

22 The early inventors had little in the way of theory to guide them. Watt had the advantage, which he acknowledges, of a knowledge of Black's doctrine of latent heat, but there was no philosophy of the relation of work to heat until long after the inventions of Watt were complete. The theory of the steam-engine as a heat-engine dates from 1824, when Carnot published his *Reflexions sur la Puissance Motrice du Feu*, and showed

that heat does work only by being let down from a higher to a lower temperature. But Carnot had no idea that any of the heat disappears in the process, and it was not until the doctrine of the conservation of energy was established in 1843 by the experiments of Joule that the Joule theory of heat engines began a vigorous growth. From 1849 onwards the science of thermodynamics was developed with extraordinary rapidity by Clausius, Rankine, Thomson, and was applied, especially by Rankine, to practical problems in the use of steam. The publication in 1859 of Rankine's *Manual of the Steam Engine* formed an epoch in the history of the subject by giving inventors a new basis, outside of mere empiricism, from which they could push on the development of the steam engine. Unfortunately, however, for its bearing on practice, the theory of the steam engine was to a great extent founded on certain simplifying assumptions which experience has now shown to be far from correct. It was assumed that the cylinder and piston might be treated as behaving to the steam like non-conducting bodies,—that the transfer of heat between the steam and the metal was negligibly small. Rankine's calculations of steam-consumption, work, and thermodynamic efficiency involve this assumption, except in the case of steam-jacketed cylinders, where he estimates that the steam in its passage through the cylinder takes just enough heat from the jacket to prevent a small amount of condensation which would otherwise occur as the process of expansion goes on. If the transfer of heat from steam to metal could be overlooked, the steam which enters the cylinder would remain during admission as dry as it was before it entered, and the volume of steam consumed per stroke would correspond with the volume of the cylinder up to the point of cut-off. It is here that the actual behaviour of steam in the cylinder diverges most widely from the behaviour which the theory assumes. When steam enters the cylinder it finds the metal chilled by the previous exhaust, and a portion of it is at once condensed. This has the effect of increasing, often very largely, the volume of boiler steam required per stroke. As expansion goes on the water that was condensed during admission begins to be re-evaporated from the sides of the cylinder, and this action is often prolonged into the exhaust. In a later chapter the effect which this exchange of heat between the metal of the cylinder and the working fluid produces on the economy of the engine will be discussed, and an account will be given of experimental means by which we may examine the amount of steam that is initially condensed and trace its subsequent re-evaporation. It is now recognized that any theory which fails to take account of these exchanges of heat fails also to yield even comparatively correct results in calculating the relative efficiency of various steam pressures or various ranges of expansion. But the exchanges of heat are so complex that there seems little prospect of submitting them to any comprehensive theoretical treatment, and we must rather look for help in the future development of engines to the scientific analysis of experiments with actual machines. Much careful work of this kind has already been done by Hirn and others, and there is room for much more. Questions relating to the influence (on heat-engine economy) of speed, of pressure, of ratio of expansion, of jacketing, of compound expansion, or of superheating must in the main be settled by an appeal to experiment,—experiment guided and interpreted at every step by reference to the principles of thermodynamics and the theory of steam.

II THEORY OF HEAT-ENGINES

Laws of thermo dynamics 23 A heat engine acts by taking in heat, converting a part of the heat received into mechanical energy, which appears as the work done by the engine, and rejecting the remainder, still in the form of heat. The theory of heat engines comprises the study of the amount of work done, in its relation to the heat supplied and to the heat rejected. The theory is based on the two laws of thermodynamics, which may be stated here as follows —

LAW 1 *When mechanical energy is produced from heat, 1 thermal unit of heat goes out of existence for every 772 foot pounds of work done, and, conversely, when heat is produced by the expenditure of mechanical energy, 1 thermal unit of heat comes into existence for every 772 foot pounds of work spent*

The "thermal unit" is the heat required to raise the temperature of 1 lb of water 1 degree Fahr when at its temperature of maximum density. The equivalent quantity of work, 772 foot-pounds, was determined by the experiments of Joule, and is called Joule's equivalent. Later researches by Joule and others have indicated that this number is probably too small, it should perhaps be as much as 774 foot-pounds. Joule's original value is still generally used by engineers, and as it enters into many published tables it may conveniently be adhered to until its accuracy is more definitely disproved. Since a definite number of foot pounds are equivalent to 1 thermal unit, we may, if we please, express quantities of work in thermal units, or quantities of heat in foot pounds, the latter practice will frequently be found useful.

LAW 2 *It is impossible for a self acting machine, unaided by any external agency, to convey heat from one body to another at a higher temperature*

This is the form in which the second law has been stated by Clausius. Another statement of it, different in form but similar in effect, has been given by Thomson. Its force may not be immediately obvious, but it will be shown below that it introduces a most important limitation of the power which any engine has of converting heat into work. So far as the first law shows, there is nothing to prevent the whole heat taken in by the engine from changing into mechanical energy. In consequence of the second law, however, no heat engine converts, or can convert, more than a small fraction of the heat supplied to it into work, a large part is necessarily rejected as heat. The ratio

Heat converted into work
Heat taken in by the engine

is a fraction always much less than unity. This ratio is called the *efficiency* of the engine considered as a heat engine.

Working substance 24 In every heat engine there is a *working substance* which takes in and rejects heat, thereby suffering changes of form, or more commonly of volume, and does work by overcoming resistance to these changes of form or volume. The working substance may be gaseous, liquid, or solid. We can, for example, imagine a heat engine in which the working substance is a long metallic rod, arranged to act as the pawl of a ratchet wheel with fine teeth. Let the rod be heated so that it elongates sufficiently to drive the wheel forward through the space of one tooth. Then let the rod be cooled (say by applying cold water), the wheel being meanwhile held from returning by a separate click or detent. The rod, on cooling, will retract so as to engage itself with the next succeeding tooth, which may then be driven forward by heating the rod again, and so on. To make it evident that such an engine would do work, we have only to suppose that the ratchet-wheel carries round with it a drum by which a weight is wound up. We have, then, a complete heat engine, in which the working substance is a solid rod, which receives heat by being brought into contact with some source of heat at a comparatively high temperature, transforms a small part of this heat into work, and rejects the remainder to what we may call a receiver of heat, at a comparatively low temperature.

Degradation of temperature The greater part of the heat may be said simply to pass through the engine, from the source to the receiver, becoming degraded as regards temperature as it goes. We shall see presently that this is typical of the action of all heat engines, when they are doing work, the heat which they reject is rejected at a temperature lower than that at which it is taken in. They convert some heat into work only by letting down a much larger quantity of heat from a high to a relatively low temperature. The action is analogous to that of a water wheel, which does work by letting down water from a high to a lower level, but with this important difference that in the transfer which occurs in heat engines an amount of heat disappears which is equivalent to the work done.

Kind of working substance 25 In almost all actual heat engines the working substance is a fluid. In some it is air, in some a mixture of several gases. In the steam engine the working fluid is a mixture (in varying proportions) of water and steam. With a fluid for working substance, work is done by changes of volume only, its amount depends solely on the relation of pressure to volume during the change, and not at all on the form of the vessels in which the change takes place. Let a diagram be drawn (fig 9) in which the relation of the intensity of pressure

to the volume of any supposed working substance is graphically exhibited by the line ABC, where AM, CN are pressures and AP, CQ are volumes, then the work done by the substance in expanding from A to C is the area of the figure MABCN. And similarly, if the substance be compressed from C back to its original volume in such a manner that the line CDA represents the relation of pressure and volume during compression, the work done upon the substance is the figure NCDAM. Taking the two operations together, we find that the substance has done a net amount of work equal to the area of the shaded figure ABCDA, or $\int P dV$. This is an example and a generalization of the method of representing work which Watt introduced by his invention of the indicator, the figure ABCDA may be called the indicator diagram of the supposed action.

Fig 9

sample and a generalization of the method of representing work which Watt introduced by his invention of the indicator, the figure ABCDA may be called the indicator diagram of the supposed action.

26 Generally in heat engines the working substance returns cyclically periodically to the same state of temperature, pressure, volume, and physical condition. When this has occurred the substance is of the same state to have passed through a complete cycle of operations. For example, in a condensing steam engine, water taken from the hot steam well is pumped into the boiler, it then passes into the cylinder as steam, passes thence into the condenser, and thence again into the hot well, it completes the cycle by returning to the same condition as at first. In other less obvious cases, as in that of the non-condensing steam engine, a little consideration will show that the cycle is completed, not indeed by the same portion of working substance being returned to the boiler, but by an equal quantity of water being fed to it, while the steam which has been discharged into the atmosphere cools to the temperature of the feed. In the theory of heat engines it is of the first importance to consider (as was first done by Carnot in 1824) the cycle of operations performed by the working substance as a complete whole. If we stop short of the completion of a cycle matters are complicated by the fact that the substance is in a state different from its initial state, and may therefore have changed its stock of internal energy. After a complete cycle, on the other hand, we know at once that, since the condition is the same, the internal energy of the substance is the same as at first, and therefore—

Heat taken in = work done + heat rejected

27 It will serve our purpose best to approach the theory of Engine heat engines by considering, in the first instance, the action of working an engine in which the working substance is any one of the with a so called permanent gases, or a mixture of them, such as air. The perfect word permanent, as applied to a gas, can now be understood only as meaning that the gas is liquefied with difficulty—either by the use of extremely low temperature or extremely high pressure or both. So long as gases are under conditions of pressure and temperature widely different from those which produce liquefaction, they conform very approximately to certain simple laws—laws which may be regarded as rigorously applicable to ideal substances called perfect gases. After stating these laws briefly we shall examine the efficiency of a heat-engine using a gas in a certain manner as working substance, and then show that the conclusion so derived has a general application to all heat engines whatsoever. In this procedure there is no sacrifice of generality, and a part of the process is of independent service in the discussion of actual air engines.

28 The laws of the permanent gases are the following — **LAW 1 (Boyle)** *The volume of a given mass of gas varies inversely as the pressure, the temperature being kept constant*. Thus, if V be the volume of 1 lb of a gas in cubic feet, and P the pressure in pounds per square foot, so long as the temperature is unchanged—

$$P \propto V^{-1}, \text{ or } PV = \text{constant}$$

For air the value of the constant is 26.220 when the temperature is 32° F .

29 **LAW 2 (Charles)** *Under constant pressure equal volumes of different gases increase equally for the same increment of temperature. Also, if a gas be heated under constant pressure, equal increments of its volume correspond very nearly to equal intervals of temperature as determined by the scale of a mercury thermometer.*

Thus, let us take, say, 493 cubic inches of hydrogen, also of oxygen, of air, &c., all at 32° F , and, keeping each at a constant pressure (not necessarily the same for all), heat all so that their temperature rises 1° F . We shall find that each has expanded by sensibly the same amount and now occupies 494 cubic inches. And further, if we heat any one through another 1° F to 33° F , we shall find that its volume is now 495 cubic inches, and so on. Thus for any gas, kept at constant pressure, if the volume was

¹ Since the liquefaction of hydrogen and other gases by J. V. Cailletet and Pictet.

increase in boiler pressure—until now there are few large land engines and scarcely any marine engines that do not employ it. In marine practice, where economy of fuel is a much more important factor in determining the design than it is on land, the principle of compound expansion has lately been greatly extended by the introduction of triple and even quadruple expansion engines, in which the steam is made to expand successively in three or in four cylinders. Even in the building of locomotive engines, where other considerations are of more moment than the saving of coal, the system of compound expansion is beginning to find a place.

The growth of compound expansion has been referred to at some length, because it forms the most distinctive improvement which the steam engine has undergone since the time of Watt. II THEORY OF HEAT-ENGINES

Laws of
thermo-
dyna-
mics

23 A heat engine acts by taking in heat, converting a part of the heat received into mechanical energy, which appears as the work done by the engine, and rejecting the remainder, still in the form of heat. The theory of heat-engines comprises the study of the amount of work done, in its relation to the heat supplied and to the heat rejected. The theory is based on the two laws of thermodynamics, which may be stated here as follows—

LAW 1 *When mechanical energy is produced from heat, 1 thermal unit of heat goes out of existence for every 772 foot pounds of work done, and, conversely, when heat is produced by the expenditure of mechanical energy, 1 thermal unit of heat comes into existence for every 772 foot pounds of work spent.*

The "thermal unit" is the heat required to raise the temperature of 1 lb of water 1 degree Fahr when at its temperature of maximum density. The equivalent quantity of work, 772 foot pounds, was determined by the experiments of Joule, and is called Joule's equivalent. Later researches by Joule and others have indicated that this number is probably too small, it should perhaps be as much as 774 foot-pounds. Joule's original value is still generally used by engineers, and as it enters into many published tables it may conveniently be adhered to until its accuracy is more definitely disproved. Since a definite number of foot pounds are equivalent to 1 thermal unit, we may, if we please, express quantities of work in thermal units, or quantities of heat in foot pounds, the latter practice will frequently be found useful.

LAW 2 *It is impossible for a self acting machine, unaided by any external agency, to convey heat from one body to another at a higher temperature.*

This is the form in which the second law has been stated by Clausius. Another statement of it, different in form but similar in effect, has been given by Thomson. Its force may not be immediately obvious, but it will be shown below that it introduces a most important limitation of the power which any engine has of converting heat into work. So far as the first law shows, there is nothing to prevent the whole heat taken in by the engine from changing into mechanical energy. In consequence of the second law, however, no heat engine converts, or can convert, more than a small fraction of the heat supplied to it into work, a large part is necessarily rejected as heat. The ratio

Heat converted into work
Heat taken in by the engine

is a fraction always much less than unity. This ratio is called the *efficiency* of the engine considered as a heat engine.

Working
sub-
stance

24 In every heat engine there is a *working substance* which takes in and rejects heat, thereby suffering changes of form, or more commonly of volume, and does work by overcoming resistance to these changes of form or volume. The working substance may be gaseous, liquid, or solid. We can, for example, imagine a heat engine in which the working substance is a long metallic rod, arranged to act as the pawl of a ratchet-wheel with fine teeth. Let the rod be heated so that it elongates sufficiently to drive the wheel forward through the space of one tooth. Then let the rod be cooled (say by applying cold water), the wheel being meanwhile held from returning by a separate click or detent. The rod, on cooling, will retract so as to engage itself with the next succeeding tooth, which may then be driven forward by heating the rod again, and so on. To make it evident that such an engine would do work, we have only to suppose that the ratchet-wheel carries round with it a drum by which a weight is wound up. We have, then, a complete heat engine, in which the working substance is a solid rod, which receives heat by being brought into contact with some source of heat at a comparatively high temperature, transforms a small part of this heat into work, and rejects the remainder to what we may call a receiver of heat, at a comparatively low temperature.

Degrada-
tion of
tempera-
ture

The greater part of the heat may be said simply to pass through the engine, from the source to the receiver, becoming degraded as regards temperature as it goes. We shall see presently that this is typical of the action of all heat engines, when they are doing work, the heat which they reject is rejected at a temperature lower than that at which it is taken in. They convert some heat into work only by letting down a much larger quantity of heat from a high to a relatively low temperature. The action is analogous to that of a water wheel, which does work by letting down water from a high to a lower level, but with this important difference that in the transfer which occurs in heat engines an amount of heat disappears which is equivalent to the work done.

fluid
working
sub-
stance
Work by
changes
of vol-
ume

25 In almost all actual heat engines the working substance is a fluid. In some it is air, in some a mixture of several gases. In the steam engine the working fluid is a mixture (in varying proportions) of water and steam. With a fluid for working substance, work is done by changes of volume only, its amount depends solely on the relation of pressure to volume during the change, and not at all on the form of the vessels in which the change takes place. Let a diagram be drawn (fig 9) in which the relation of the intensity of pressure

to the volume of any supposed working substance is graphically exhibited by the line ABC, where AM, CN are pressures and AP, CQ are volumes, then the work done by the substance in expanding from A to C is the area of the figure MABCN. And similarly, if the substance be compressed from C back to its original volume in such a manner that the line CDA represents the relation of pressure and volume during compression, the work done upon the substance is the figure NCDAM. Taking the two operations together, we find that the substance has done a net amount of work equal to the area of the shaded figure ABCDA, or $\int P dV$. This is an example and a generalization of the method of representing work which Watt introduced by his invention of the indicator, the figure ABCDA may be called the indicator diagram of the supposed action.

Fig 9

26 Generally in heat engines the working substance returns cyclically to the same state of temperature, pressure, volume, operation and physical condition. When this has occurred the substance is said to have passed through a complete cycle of operations. For example, in a condensing steam engine, water taken from the hot well is pumped into the boiler, it then passes into the cylinder as steam, passes thence into the condenser, and thence again into the hot well, it completes the cycle by returning to the same condition as at first. In other less obvious cases, as in that of the non condensing steam engine, a little consideration will show that the cycle is completed, not indeed by the same portion of working substance being returned to the boiler, but by an equal quantity of water being fed to it, while the steam which has been discharged into the atmosphere cools to the temperature of the feed. In the theory of heat engines it is of the first importance to consider (as was first done by Carnot in 1824) the cycle of operations performed by the working substance as a complete whole. If we stop short of the completion of a cycle matters are complicated by the fact that the substance is in a state different from its initial state, and may therefore have changed its stock of internal energy. After a complete cycle, on the other hand, we know at once that, since the condition is the same, the internal energy of the substance is the same as at first, and therefore—

Heat taken in = work done + heat rejected

27 It will serve our purpose best to approach the theory of Engine heat engines by considering, in the first instance, the action of working an engine in which the working substance is any one of the with a so called permanent gases, or a mixture of them, such as air. The perfect word permanent, as applied to a gas, can now be understood only as meaning that the gas is liquefied with difficulty—either by the use of extremely low temperature or extremely high pressure or both. So long as gases are under conditions of pressure and temperature widely different from those which produce liquefaction, they conform very approximately to certain simple laws—laws which may be regarded as rigorously applicable to ideal substances called *perfect gases*. After stating these laws briefly we shall examine the efficiency of a heat-engine using a gas in a certain manner as working substance, and then show that the conclusion so derived has a general application to all heat engines whatsoever. In this procedure there is no sacrifice of generality, and a part of the process is of independent service in the discussion of actual air engines.

28 The laws of the permanent gases are the following—
LAW 1 (Boyle) *The volume of a given mass of gas varies inversely as the pressure, the temperature being kept constant.*
Thus, if V be the volume of 1 lb of a gas in cubic feet, and P the pressure in pounds per square foot, so long as the temperature is unchanged—

$$P \propto V^{-1}, \text{ or } PV = \text{constant}$$

For an the value of the constant is 26220 when the temperature is 32° F.

29 **LAW 2 (Charles)** *Under constant pressure equal volumes of different gases increase equally for the same increment of temperature. Also, if a gas be heated under constant pressure, equal increments of its volume correspond very nearly to equal intervals of temperature as determined by the scale of a mercury thermometer.*

Thus, let us take, say, 493 cubic inches of hydrogen, also of oxygen, of air, &c., all at 32° F, and, keeping each at a constant pressure (not necessarily the same for all), heat all so that their temperature rises 1° F. We shall find that each has expanded by sensibly the same amount and now occupies 494 cubic inches. And further, if we heat any one through another 1° F to 34° F, we shall find that its volume is now 495 cubic inches, and so on. Thus for any gas, kept at constant pressure, if the volume was

¹ Since the liquefaction of hydrogen and other gases by MM. Cailletet and Pictet.

it would be

493 at 32° F,
492 at 31° F,
461 at 0° F,

and finally 0 at -461° F, provided the same law were to hold at indefinitely low temperatures. This we may assume to be the case with a perfect gas, although any actual gas would change its physical state long before so low a temperature were reached.

Absolute temperature. This result may be concisely expressed by saying that if we reckon temperature, not from the ordinary zero but from a point 461° below the zero of Fahrenheit's scale, the volume of a given quantity of a gas, kept at constant pressure, is proportional to the temperature reckoned from that zero. Temperatures so reckoned are called absolute temperatures, and the point -461° F is called the absolute zero of temperature. Denoting any temperature according to the ordinary scale by t , and the corresponding absolute temperature by τ , we have

$$\tau = t + 461 \text{ on the Fahrenheit scale,}$$

$$\tau = t + 273 \text{ on the Centigrade scale}$$

and Charles's law shows that if temperatures be measured by thermometers in which the expanding substance is air, hydrogen, oxygen, or any other permanent gas, and, if those intervals of temperature be called equal which correspond to equal amounts of expansion, then the indications of these thermometers always agree very closely with each other, and also agree, though less closely, with the indications of a mercury thermometer. We shall see later that the theory of heat engines affords a means of forming a thermometric scale which is independent of the properties, as to expansion, of any substance, and that this scale coincides with the scale of a perfect gas thermometer, a fact which justifies the use of the term absolute, as applied to temperatures measured by the expansion of a gas.

30 Combining laws 1 and 2, we have, for a given mass of any gas,

$$PV = c\tau,$$

where c is a constant depending on the specific density of the gas and on the units in which P and V are measured. In what follows we shall assume that P is measured in pounds per square foot, that V is the volume of 1 lb in cubic feet, and that τ is the absolute temperature in Fahrenheit degrees. In air, with these units,

$$PV = 53.18\tau$$

Regnault's law. 31 LAW 3 (Regnault) The specific heat at constant pressure is constant for any gas.

By specific heat at constant pressure is meant the heat taken in by 1 lb of a substance when its temperature rises 1° F, while the pressure remains unchanged—the volume of course increasing. The law states that this quantity is the same for any one gas, no matter what be the temperature, or what the constant pressure, at which the process of heating takes place.

Specific heat at constant volume. 32 Another important quantity in the theory of heat engines is the specific heat at constant volume, that is, the heat taken in by 1 lb of the substance when its temperature rises 1° F while the volume remains unchanged—the pressure of course increasing. We shall denote specific heat at constant pressure by K_p and specific heat at constant volume by K_v . Let 1 lb of a gas be heated at constant pressure P from temperature τ_1 to temperature τ_2 (absolute). Let V_1 be the volume at τ_1 and V_2 the volume at τ_2 . Heat is taken in, and external work is done by the expansion of the gas, namely—

$$\text{Heat taken in} = K_p(\tau_2 - \tau_1)$$

$$\text{Work done} = P(V_2 - V_1) = c(\tau_2 - \tau_1)$$

The difference between these quantities, or $(K_p - c)(\tau_2 - \tau_1)$, is the amount by which the stock of internal energy possessed by the gas has increased during the process. We shall see presently that this gain of internal energy would have been the same had the gas passed in any other manner from τ_1 to τ_2 .

Joule's law. 33 LAW 4 (Joule) When a gas expands without doing external work, and without taking in or giving out heat, its temperature does not change.

To prove this, Joule connected a vessel containing compressed gas with another vessel that was empty, by means of a pipe with a closed stop-cock. Both vessels were immersed in a tub of water and were allowed to assume a uniform temperature. Then the stop-cock was opened, the gas expanded without doing external work, and finally the temperature of the water in the tub was found to have undergone no change. The temperature of the gas was unaltered, and no heat had been taken in or given out by it.

Internal energy of a gas depends only on temperature. 34 Since the gas had neither gained nor lost heat, and had done no work, its internal energy was the same at the end as at the beginning of the experiment. The pressure and volume had changed, but the temperature had not. We must therefore conclude that the internal energy of a given mass of a gas depends only on its temperature, and not upon its pressure or volume, in other words, a change of pressure and volume not associated with a change of temperature does not alter the internal energy. Hence

in any change of temperature the change of internal energy is independent of the relation of pressure to volume throughout the operation. Now we have seen above that the quantity

$$(K_p - c)(\tau_2 - \tau_1)$$

measures the gain of internal energy when 1 lb of a gas has its temperature changed from τ_1 to τ_2 in one particular way, namely, at constant pressure. Hence this same quantity also measures the gain of internal energy when 1 lb of a gas has its temperature changed from τ_1 to τ_2 in any manner whatsoever.

35 Next consider the case of 1 lb of a gas heated from τ_1 to τ_2 at constant volume. The heat taken in is

$$K_v(\tau_2 - \tau_1)$$

Since no work is done, this is all gain of internal energy, and is therefore (§ 34) equal to

$$(K_p - c)(\tau_2 - \tau_1)$$

Hence in any gas

$$K_p - c = K_v$$

The ratio K_p/K_v will be denoted by γ , obviously $K_v = c/(\gamma - 1)$. The following table of values of K_p , K_v , c , and γ will be found useful in dealing with air and gas engines.

TABLE I — Properties of Gases

	K_p	K_v	c	γ
	Foot lbs	Foot lbs	Foot lbs	
Dry air	183.1	130.2	53.2	1.409
Oxygen	167.9	119.8	48.1	1.402
Nitrogen	183.2	133.4	54.8	1.411
Hydrogen	2632	1864	768	1.412
Carbonic oxide	189.1	133.4	55.7	1.418
Carbonic acid	167.4	132.6	34.8	1.263
Marsh gas	457.7	363.1	94.6	1.261
Olefiant gas	311.9	257.7	54.2	1.213
Steam gas, or highly superheated steam	371	235.5	85.5	1.30

36 We shall now return to the consideration of diagrams like that of § 25, which exhibit the action of a working substance by curves showing the relation of P to V during expansion or compression. In most of the instances which occur in the theory of heat engines such curves may be exactly or approximately represented by equations of the form

$$PV^n = \text{constant},$$

where the index n has various numerical values. Let AB , fig 10, be a curve of expansion (of any substance) in which PV^n is constant, from pressure P_1 and volume V_1 at A to pressure P_2 and volume V_2 at B . We have, by assumption,

$$P_1 V_1^n = P_2 V_2^n$$

The work done is

$$\int_{V_1}^{V_2} P dV = P_1 V_1^n \int_{V_1}^{V_2} \frac{dV}{V^n} = \frac{P_1 V_1^n (V_2^{1-n} - V_1^{1-n})}{1-n}$$

This may also be written

$$\frac{P_1 V_1 (1 - r^{1-n})}{n-1},$$

where r is the ratio V_2/V_1 , which may be called the ratio of expansion.

Still another form of the above expression for the work done is

$$\frac{P_1 V_1 - P_2 V_2}{n-1}$$

37 Applying this result to the case of an expanding gas, we have

$$\text{Work done} = c(\tau_1 - \tau_2)/(n-1)$$

The loss of internal energy during expansion is, by § 34,

$$K_v(\tau_1 - \tau_2), \text{ or } c(\tau_1 - \tau_2)/(\gamma - 1), \text{ by § 35}$$

Suppose now that the mode of expansion is such that the loss of internal energy is equal to the external work done, then

$$\frac{c(\tau_1 - \tau_2)}{n-1} = \frac{c(\tau_1 - \tau_2)}{\gamma-1}, \text{ or } n = \gamma,$$

and the law of expansion is

$$PV\gamma = \text{constant}$$

The same formula applies when a gas is being compressed in such a manner that the work spent upon the gas is equal to the gain of internal energy by the gas.

38 This mode of expansion (or compression) is termed *adiabatic*. It occurs when the working substance is neither gaining nor losing heat by conduction or radiation or internal chemical action. It would be realized if we had a substance expanding or being compressed, without chemical change, in a cylinder which (with the piston) was a perfect non conductor of heat. In adiabatic

Fig 10

expansion the external work is done entirely at the expense of the substance's stock of internal energy. Hence in the adiabatic expansion of a gas the temperature falls, and in adiabatic compression it rises. To find the change of temperature in a gas when expanded or compressed adiabatically we have only to combine the equations

$$P_1 V_1^\gamma = P_2 V_2^\gamma \text{ and } \frac{P_2 V_2}{P_1 V_1} = \frac{\tau_2}{\tau_1},$$

and we find

$$\tau_2 = \tau_1 (V_1/V_2)^{\gamma-1}$$

It is clear from the above that if, during expansion, n is less than γ the fluid is taking in heat, and if n is greater than γ the fluid is rejecting heat.

Iso-
thermal
expan-
sion.

39 Another very important mode of expansion or compression is that called *isothermal*, in which the temperature of the working substance is kept constant during the process.

In the case of a gas the curve of isothermal expansion is a rectangular hyperbola, having the equation

$$PV = \text{constant} = cr$$

When a gas expands (or is compressed) isothermally at temperature τ from V_1 to V_2 the work done by (or upon) it (per lb) is

$$\int_{V_1}^{V_2} P dV = P_1 \int_{V_1}^{V_2} \frac{dV}{V} = PV \log_e r = cr \log_e r,$$

where r is the ratio V_2/V_1 as before.¹

During isothermal expansion or compression a gas suffers no change of internal energy (by § 34, since τ is constant). Hence during isothermal expansion a gas must take in an amount of heat just equal to the work it does, and during isothermal compression it must reject an amount of heat just equal to the work spent upon it. The expression $cr \log_e r$ consequently measures, not only the work done by or upon the gas, but also the heat taken in during isothermal expansion or given out during isothermal compression. In the diagram, fig 11,

FIG 11.

the line AB is an example of a curve of isothermal expansion for a perfect gas, called for brevity an *isothermal line*, while AC is an adiabatic line starting from the same point A.

Carnot's
cycle of
opera-
tions

40 We shall now consider the action of an ideal engine in which the working substance is a perfect gas, and is caused to pass through a cycle of changes each of which is either isothermal or adiabatic. The cycle to be described was first examined by Carnot, and is spoken of as *Carnot's cycle of operations*. Imagine a cylinder and piston composed of a perfectly non-conducting material, except as regards the bottom of the cylinder, which is a conductor. Imagine also a hot body or indefinitely capacious source of heat A, kept always at a temperature τ_1 , a perfectly non-conducting cover B, and a cold body or indefinitely capacious receiver of heat C, kept always at a temperature τ_2 , which is lower than τ_1 . It is supposed that A, B, or C can be applied to the bottom of the cylinder. Let the cylinder contain 1 lb of a perfect gas, at temperature τ_1 , volume V_a , and pressure P_a to begin with. The suffixes refer to the points on the indicator diagram, fig 12.

FIG 12.—Carnot's Cycle, with a gas for working substance.

(1) Apply A, and allow the piston to rise. The gas expands isothermally at τ_1 , taking heat from A and doing work. The pressure changes to P_b and the volume to V_b .

(2) Remove A and apply B. Allow the piston to go on rising. The gas expands adiabatically, doing work at the expense of its internal energy, and the temperature falls. Let this go on until the temperature is τ_2 . The pressure is then P_c , and the volume V_c .

(3) Remove B and apply C. Force the piston down. The gas is compressed isothermally at τ_2 , since the smallest increase of temperature above τ_2 causes heat to pass into C. Work is spent upon the gas, and heat is rejected to C. Let this be continued until a certain point d (fig 12) is reached, such that the fourth operation will complete the cycle.

(4) Remove C and apply B. Continue the compression, which is now adiabatic. The pressure and temperature rise, and if the point d has been properly chosen, when the pressure is restored to its original value P_a , the temperature will also have risen to its

¹ In calculations where this expression is involved it is convenient to remember that \log_e , the hyperbolic logarithm, of any number is 2.3026 times the common logarithm of the number.

original value τ_1 . [In other words, the third operation must be stopped when a point d is reached such that an adiabatic line drawn through d will pass through a .] This completes the cycle.

To find the proper place at which to stop the third operation, we have, by § 38, $\tau_1/\tau_2 = (V_c/V_b)^{\gamma-1}$ in the second operation, and again $\tau_1/\tau_2 = (V_d/V_a)^{\gamma-1}$ in the fourth operation. Hence $V_c/V_b = V_d/V_a$, and V_b/V_c , the ratio of isothermal expansion, is equal to V_c/V_d , the ratio of isothermal compression. For brevity we shall denote either of these last ratios by r .

41 The following are the transfers of heat to and from the working fluid, in successive stages of the cycle —

- (1) Heat taken in from A = $cr_1 \log_e r$ (by § 39)
- (2) No heat taken in or rejected
- (3) Heat rejected to C = $cr_2 \log_e r$ (by § 39)
- (4) No heat taken in or rejected.

Hence, by the first law of thermodynamics, the net external work done by the gas is

$$c(\tau_1 - \tau_2) \log_e r,$$

and the efficiency of the engine (§ 23) is

$$\frac{c(\tau_1 - \tau_2) \log_e r}{cr_1 \log_e r} = \frac{\tau_1 - \tau_2}{\tau_1}$$

This is the fraction of the whole heat given to it which an engine following Carnot's cycle converts into work. The engine takes in an amount of heat, at the temperature of the source, proportional to τ_1 , it rejects an amount of heat, at the temperature of the receiver, proportional to τ_2 . It works within a range of temperature extending from τ_1 to τ_2 , by letting down heat from τ_1 to τ_2 (§ 24), and in the process it converts into work a fraction of that heat, which fraction will be greater the lower the temperature τ_2 at which heat is rejected is below the temperature τ_1 at which heat is received.

42 Next let us consider what will happen if we reverse Carnot's cycle, that is to say, if we force this engine to act so that the same cycle indicator diagram as before is traced out, but in the direction reversed, opposite to that followed in § 40. Starting as before from the point a and with the gas at τ_1 , we shall require the following four operations —

- (1) Apply B and allow the piston to rise. The gas expands adiabatically, the curve traced is ad , and when d is reached the temperature has fallen to τ_2 .
- (2) Remove B and apply C. Allow the piston to go on rising. The gas expands isothermally at τ_2 , taking heat from C, and the curve dc is traced.
- (3) Remove C and apply B. Compress the gas. The process is adiabatic. The curve traced is cb , and when b is reached the temperature has risen to τ_1 .
- (4) Remove B and apply A. Continue the compression, which is now isothermal, at τ_1 . Heat is now rejected to A, and the cycle is completed by the curve ba .

In this process the engine is not doing work, on the contrary, work is spent upon it equal to the area of the diagram, or $c(\tau_1 - \tau_2) \log_e r$. Heat is taken in from C in the first operation, to the amount $cr_2 \log_e r$. Heat is rejected to A in the fourth operation, to the amount $cr_1 \log_e r$. In the first and third operations there is no transfer of heat.

The action is now in every respect the reverse of what it was before. The same work is now spent upon the engine as was formerly done by it. The same amount of heat is now given to the hot body A as was formerly taken from it. The same amount of heat is now taken from the cold body C as was formerly given to it, as will be seen by the following scheme —

Carnot's Cycle, Direct

Work done by the engine = $c(\tau_1 - \tau_2) \log_e r$,
Heat taken from A = $cr_1 \log_e r$,
Heat rejected to C = $cr_2 \log_e r$

Carnot's Cycle, Reversed

Work spent upon the engine = $c(\tau_1 - \tau_2) \log_e r$,
Heat rejected to A = $cr_1 \log_e r$,
Heat taken from C = $cr_2 \log_e r$

The reversal of the work has been accompanied by an exact reversal of each of the transfers of heat.

43 An engine in which this is possible is called, from the Reversible thermodynamic point of view, a *reversible engine*. In other words, it is a reversible heat engine is one which, if forced to trace out its engine indicator diagram reversed in direction, so that the work which would be done by the engine, when running direct, is actually spent upon it, will reject to the source of heat the same quantity of heat as, when running direct, it would take from the source, and will take from the receiver of heat the same quantity as, when running direct, it would reject to the receiver. By "the source of heat" is meant the hot body which acts as source, and by "the receiver" is meant the cold body which acts as receiver, when the

engine is running direct. Carnot's engine is one example of a reversible engine. The idea of thermodynamic reversibility is highly important, for the reason that no heat-engine can be more efficient than a reversible engine, if both take in and reject heat at the same pair of temperatures.

Reversibility the test of per sec 102 in a heat engine

44 To prove this, let it be supposed that we have two engines M and N , of which N is reversible in the above sense, and that we have a hot body A capable of acting as a source of heat, and a cold body C capable of acting as a receiver of heat. The engine M is set to work as a heat-engine, taking heat from A and rejecting heat to C . To prove that M cannot be more efficient than the reversible engine N , we shall assume that it is more efficient, and trace the consequences of that assumption.

Let M , working direct, be coupled so as to work N reversed, if we suppose that the engines are without mechanical friction, and can be coupled up without loss of power, the work represented by the indicator diagram of M is spent on N , and N will therefore reject to A an amount of heat which we will call Q_A and take from B an amount of heat which we will call Q_B . Now since N is reversible, if it worked direct, taking Q_A from A , it would do the same amount of work as in the supposed circumstances, is spent upon it. Hence, if M is more efficient than N it is taking from A an amount of heat less than Q_A , and consequently also is giving to B an amount of heat correspondingly less than Q_B . The joint effect, therefore, of M working direct and N working reversed is that the heat taken from A by M is less than the heat given to A by N , while the heat given to B by M is less (to an equal extent) than the heat taken from B by N . The consequence is that the hot body A is gaining heat on the whole, and the cold body B is losing an equal amount of heat, in other words, with the continued action of the double system heat passes, in indefinitely large quantity, from a cold body to a hot body, by means of an agency which, it is to be observed, is purely self-acting, for if we suppose there is no mechanical friction the system requires no help from without. Now this result is, by the second law of thermodynamics (§ 23), contrary to all experience, and we are forced to conclude that the assumption that M is more efficient than the reversible engine N , when both take in and reject heat at the same two temperatures, is false. Hence, with given temperatures of source and receiver of heat no engine is more efficient than a reversible engine.

Next, let M and N both be reversible and both work between the same limits, but be different in any other respect. Then by the foregoing argument M cannot be more efficient than N , neither can N be more efficient than M . Hence all reversible heat-engines taking in and rejecting heat at the same temperatures are equally efficient.

45 These results imply that reversibility, in the thermodynamic sense, is the criterion of what may be called perfection in a heat-engine. A reversible engine is perfect in the sense that it cannot be improved on as regards efficiency: no other engine, taking in and rejecting heat at the same temperatures, will convert into work a greater fraction of the heat which it takes in. Moreover, if this criterion be satisfied, it is as regards efficiency a matter of complete indifference what is the nature of the working substance, or what, in other respects, is the mode of the engine's action.

Efficiency of a perfect heat engine.

46 Further, since all engines that are reversible are equally efficient, provided they work between the same temperatures, an expression for the efficiency of one will apply equally to all. Now, the engine whose efficiency we have found in § 41 is one example of a reversible engine. Hence its efficiency

$$(\tau_1 - \tau_2) / \tau_1$$

is the efficiency of any reversible heat-engine whatsoever taking in heat at τ_1 and rejecting heat at τ_2 . And, as no engine can be more efficient than one that is reversible, this expression is the measure of perfect efficiency. We have thus arrived at the immensely important conclusion that no heat-engine can convert into work a greater fraction of the heat which it receives than is expressed by the excess of the temperature of reception above that of rejection divided by the absolute temperature of reception.

can be reached

47 Briefly recapitulated, the steps of the argument by which this result has been reached are as follows. After stating the experimental laws to which gases conform, we examined the action of a heat-engine in which the working substance took in heat when at the temperature of the source and rejected heat when at the temperature of the receiver, the change of temperature from one to the other of these limits being accomplished by a diabatic expansion and adiabatic compression. Taking a special case in which this engine had for its working substance a perfect gas we found that its efficiency was $(\tau_1 - \tau_2) / \tau_1$ (§ 41). We also observed that it was, in the thermodynamic sense, a reversible engine (§ 43). Then we found, by an application of the second law of thermodynamics, that no heat-engine can have a higher efficiency than a reversible engine, when taking in and giving out heat at the same two temperatures τ_1 and τ_2 , this was shown by the fact that a contrary assumption leads to a violation of the second law (§ 44). Hence, we concluded that all reversible heat-engines receiving and rejecting heat at the same temperatures τ_1

and τ_2 respectively are equally efficient, and hence that the efficiency $(\tau_1 - \tau_2) / \tau_1$, already determined for one particular reversible engine, measures the efficiency of any reversible engine, and is a limit of efficiency which no engine whatever can exceed.

48 The second law of thermodynamics, on which (along with Second the first law) this conclusion rests has been given in many different law of forms. The statement of it in § 23 is that of Clausius, and is thermodynamically very similar to that of Sir W. Thomson. Rankine, to whom with Thomson and Clausius is due the development of the theory of heat-engines from the point at which Carnot left it, has stated the second law in a form which is neither easy to understand, nor obvious, as an experimental result, when understood. His statement runs —

"If the absolute temperature of any uniformly hot substance be divided into any number of equal parts, the effects of those parts in causing work to be performed are equal."

To make this intelligible we may suppose that any quantity q of heat from a source at temperature τ_1 is taken by the first of a series of perfect heat-engines, and that this engine rejects heat at a temperature τ_2 less than τ_1 by a certain interval $\Delta\tau$. Let the heat so rejected by the first engine form the heat supply of a second perfect engine working from τ_2 to τ_3 through an equal interval $\Delta\tau$, let the heat which it in turn rejects form the heat-supply of a third perfect engine working again through an equal interval from τ_3 to τ_4 , and so on. The efficiencies of the several engines

are (by § 46) $\frac{\Delta\tau}{\tau_1}, \frac{\Delta\tau}{\tau_2}, \frac{\Delta\tau}{\tau_3}$, &c. The amounts of heat supplied to them are $q, q \frac{\tau_2}{\tau_1}, q \frac{\tau_3}{\tau_2}$, &c. Hence the amount of work done by

each engine is the same, namely, $q \frac{\Delta\tau}{\tau_1}$. Thus Rankine's statement

is to be understood as meaning that each of the equal intervals into which any range of temperature may be divided is equally effective in allowing work to be produced from heat when heat is made to pass, doing work in the most efficient possible way, through all the intervals from the top to the bottom of the range.

49 A point of much theoretical interest may be noted in passing. Thermodynamic expansion of a perfect gas, as we have done, by the dynamical expansion of a perfect gas, a scale of temperature might be formed absolute thus. Starting from any one temperature, let a series of intervals measure be taken such that a series of reversible engines, each working between one of the intervals for its range, in the manner described in § 48 (so that the heat rejected by the first forms the heat supply of the second, and so on), will each do the same amount of work, then call these intervals equal. This gives a scale of temperature (originally suggested by Sir W. Thomson) which is truly absolute in the sense of being independent of the properties of any substance, it coincides, as is evident from § 48, with the scale we have been using, in which equal intervals of temperature are defined as those corresponding to equal amounts of expansion of a perfect gas under constant pressure, and it coincides approximately with the scale of a mercury thermometer when that is graduated to read from the absolute zero by the addition of a suitable constant (§ 29).

50 The availability of heat for transformation into work depends essentially on the range of temperature through which the heat is let down from the hot source to the cold body into which maximum heat is rejected, it is only in virtue of a difference of temperature between bodies that conversion of any part of their heat into work becomes possible. If τ_1 and τ_2 are the highest and lowest temperatures of the range through which a heat-engine works, it is clear that the maximum of efficiency can be reached only when the engine takes in all its heat at τ_1 and rejects at τ_2 all that is rejected. With respect to every portion of heat taken in and rejected the greatest ideal efficiency is

$$\frac{\text{Temperature of reception} - \text{temperature of rejection}}{\text{Temperature of reception}}$$

Any heat taken in at a temperature below τ_1 or rejected at a temperature above τ_2 will have less availability for conversion into work than if taken in at τ_1 and rejected at τ_2 , and hence, with a given pair of limiting temperatures, it is essential to maximum efficiency that no heat be taken in by the engine except at the top of the range, and no heat rejected except at the bottom of the range. Further, as we have seen in § 45, when the temperatures at which maximum efficiency is received and rejected are assigned, an engine attains the maximum of efficiency if it be reversible.

51 It is therefore important to inquire more particularly what kinds of action are reversible in the thermodynamic sense. A little consideration will show that a transfer of heat from the source or to the receiver is reversible only when the working substance is at bilaterally the same temperature as the source or the receiver, as the case may be, and an expansion is reversible only when it occurs by the gradual displacement of some part of the containing envelope in such a manner that the expanding fluid does external work on the envelope, and does not waste energy to any sensible extent in setting itself in motion. This excludes what may be termed free expansion,

such as that of the gas in Joule's experiment, § 38, and it excludes also what may be called imperfectly-resisted expansion, such as would occur if the fluid were allowed to expand into a closed chamber in which the pressure was less than that of the fluid, or if the piston in a cylinder rose so fast as to cause, through the inertia of the expanding fluid, local variations of pressure throughout the cylinder.

To make a heat engine, working within given limits of temperature, as efficient as possible we must therefore strive—(1) to take in no heat except at the highest temperature, and to reject no heat except at the lowest temperature, (2) to secure that the working substance shall, when receiving heat, be at the temperature of the body from which the heat comes, and that it shall, when giving up heat, be at the temperature of the body to which heat is given up, (3) to avoid free or imperfectly resisted expansion. If these conditions are fulfilled the engine is a perfect heat engine.

Temper-
ature of
working
substance
changed
by adia-
batic ex-
pansion
or com-
pression

The first and second of these conditions are satisfied if in the action of the engine the working substance changes its temperature from τ_1 to τ_2 by adiabatic expansion, and from τ_2 to τ_1 by adiabatic compression, thereby being enabled to take in and reject heat at the ends of the range without taking in or rejecting any by the way. This is the action in Carnot's engine (§ 40).

Regen-
erative
prin-
ciple

52 But if we can cause the working substance to deposit heat in some body within the engine while passing from τ_1 to τ_2 , in such a manner that the transfer of heat from the substance to this body is reversible (satisfying the second condition above), then when we wish the working substance to pass from τ_2 to τ_1 we may reverse this transfer and so recover the heat that was deposited in this body. This alternate storing and restoring of heat may then take the place of adiabatic expansion and compression, in causing the temperature of the working substance to pass from τ_1 to τ_2 and from τ_2 to τ_1 respectively. The alternate storing and restoring is an action occurring wholly within the engine, and is therefore distinct from the taking in and rejecting of heat by the engine.

Stirling's
regenera-
tor

53 In 1827 Robert Stirling designed an apparatus, called a *regenerator*, by which this process of alternate storing and restoring of heat could be actually performed. For the present purpose it will suffice to describe the regenerator as a passage through which the working fluid can travel in either direction, whose walls have a very large capacity for heat, so that the amount alternately given to or taken from them by the working fluid causes no more than an insensible rise or fall in their temperature. The temperature of the walls at one end of the passage is τ_1 , and this tapers continuously down to τ_2 at the other end. When the working fluid at temperature τ_1 enters the hot end and passes through, it comes out at the cold end at temperature τ_2 , having stored in the walls of the regenerator an amount of heat which it will pick up again when passed through in the opposite direction. During the return journey its temperature rises from τ_2 to τ_1 . The process is strictly reversible, or rather would be so if the regenerator had an unlimited capacity for heat, if no conduction of heat took place along its walls from the hot to the cold end, and if no loss took place by conduction or radiation from its external surface.

Cycle in
Stirling's
engine

54 Using air as the working substance, and employing his regenerator, Stirling made an engine (to be described later) which, allowing for practical imperfections, is the earliest example of a truly reversible engine. The cycle of operations in Stirling's engine is substantially this—

(1) Air (which has been heated to τ_1 by passing through the regenerator) is allowed to expand isothermally through a ratio τ , taking in heat from a furnace and raising a piston. Heat taken in (per lb of air) = $c\tau_1 \log_e \tau$.

(2) The air is caused to pass through the regenerator from the hot to the cold end, depositing heat and having its temperature lowered to τ_2 , without change of volume. Heat stored in regenerator = $K_p(\tau_1 - \tau_2)$. The pressure of course falls.

(3) The air is then compressed isothermally to its original volume at τ_2 in contact with a refrigerator (or receiver of heat). Heat rejected = $c\tau_2 \log_e \tau$.

(4) The air is again passed through the regenerator from the cold to the hot end, taking up heat and having its temperature raised to τ_1 . Heat restored by the regenerator = $K_p(\tau_1 - \tau_2)$.

$$\text{Efficiency} = \frac{c\tau_1 \log_e \tau - c\tau_2 \log_e \tau}{c\tau_1 \log_e \tau} = \frac{\tau_1 - \tau_2}{\tau_1}$$

The indicator diagram of the action is shown in fig 13, and a diagram of the engine is given in chap XIV. Stirling's engine is important, not as a present day heat engine (though it has recently been revived in small forms after a long interval of disuse), but because it is typical of the only mode, other than Carnot's plan of adiabatic expansion and compression, by which the action of a heat engine can be made reversible. Valuable as the regenerator has proved in metallurgy and other industrial processes, its actual application to heat engines has hitherto been very limited. An

FIG 13.—Air Engine with Regenerator (Stirling).

other way of using it in air-engines was designed by Ericsson, and attempts have been made by C W Siemens and F Jenkin to apply it to steam engines and to gas-engines. But almost all actual engines, in so far as they can be said to approach the condition of reversibility, do so, not by the use of the regenerative principle, but by more or less nearly adiabatic expansion and compression after the manner of Carnot's ideal engine.

III PROPERTIES OF STEAM AND THEORY OF THE STEAM ENGINE.

55 We have now to consider the action of heat engines in form which the working substance is water and water vapour or steam. The properties of steam are most conveniently stated by steam referring in the first instance to what happens when steam is under formed under constant pressure. This is substantially the process constant which occurs in the boiler of a steam engine when the engine is pressure. at work. To fix the ideas we may suppose that the vessel in which steam is to be formed is a long upright cylinder fitted with a piston which may be loaded so that it exerts a constant pressure on the fluid below. Let there be, to begin with, at the foot of the cylinder a quantity of water (which for convenience of numerical statement we shall take as 1 lb), at any temperature t_0 , and let the piston press on the surface of the water with a force of P lb per square foot. Let heat now be applied to the bottom of the cylinder. As it enters the water it will produce the following effects in three stages—

(1) The temperature of the water rises until a certain temperature t is reached, at which steam begins to be formed. The value of t depends on the particular pressure P which the piston exerts. Until the temperature t is reached there is nothing but water below the piston.

(2) Steam is formed, more heat being taken in. The piston (which is supposed to exert a constant pressure) rises. No further increase of temperature occurs during this stage, which continues until all the water is converted into steam. During this stage the steam which is formed is said to be *saturated*. The volume which the piston encloses at the end of this stage, — the volume, namely, of 1 lb of saturated steam at pressure P (and temperature t), — will be denoted by V in cubic feet.

(3) If after all the water is converted into steam more heat be allowed to enter, the volume will increase and the temperature will rise. The steam is then said to be *superheated*.

56 The difference between saturated and superheated steam may be expressed by saying that if water (at the temperature of and super the steam) be mixed with steam some of the water will be evaporated heated if the steam is superheated, but none if the steam is saturated steam. Any vapour in contact with its liquid and in thermal equilibrium is necessarily saturated. When saturated its properties differ considerably, as a rule, from those of a perfect gas, but when super heated they approach those of a perfect gas more and more closely the farther the process of superheating is carried, that is to say, the more the temperature is raised above t , the temperature of saturation corresponding to the given pressure P .

57 The temperature t at which steam is formed depends on the Relation value of P . Their relation was determined with great care by of pres-Regnault, in a series of classical experiments on which our sure and knowledge of the properties of steam chiefly depends.¹ The tempera- pressure of saturated steam rises with the temperature at a rate in which increases rapidly in the upper regions of the scale. This saturated will be apparent from the first and second columns of Table II, steam given on next page, which is compiled from Rankine's reduction of Regnault's results. The first column gives the temperature on the Fahr scale, the second gives the corresponding pressure in pounds per square inch. Rankine has also expressed the relation of temperature and pressure in saturated steam by the following formula (which is applicable with other constants to other vapours)²—

$$\log p = 6.1007 - \frac{2732}{\tau} - \frac{396945}{\tau^2},$$

where p is the pressure in pounds per square inch, and τ is the absolute temperature in Fahr degrees. For most purposes, however, it is more convenient to find the pressure corresponding to a given temperature, or the temperature corresponding to a given pressure, from the table by interpolation.

58 The same table shows the volume V , in cubic feet, occupied Relation by 1 lb of saturated steam at each pressure. This is a quantity of pres- the direct experimental measurement of which is of very great sure and difficulty. It may, however, be calculated, from a knowledge of volume other properties of steam, by a process which will be described later (§ 75). The values of V given in the table were determined by Rankine by means of this process, they agree fairly well with such direct observations of the density of steam as have been hitherto

¹ *Mém Inst France*, 1847, vol xvi. An account of Regnault's methods of experiment and a statement of his results expressed in British measures will be found in Dixon's *Treatise on Heat*.

made.¹ The relation of P to V may be approximately expressed by the formula²

$$PV^{1.17} = \text{constant} = 68500 \text{ (nearly),}$$

when P is stated in lb per sq ft. and V in cub ft. per lb

Supply of heat. 59 We have next to consider the supply of heat. During the first stage, until the temperature rises from its initial value t_0 to t_1 , the temperature at which steam begins to form under the given pressure, heat is required only to warm the water. Since the specific heat of water is nearly constant, the amount of heat taken in during the first stage is approximately $t - t_0$ thermal units or $J(t - t_0)$ foot pounds, J being Joule's equivalent (§ 23), and thus expression for it will generally serve with sufficient accuracy in practical calculations. More exactly, however, the heat taken in is somewhat greater than this, for Regnault's experiments show that the specific heat of water increases slightly as the temperature rises. In stating the amount of heat required for this first stage, t_0 must be taken as a known temperature, for convenience in numerical statement the temperature 32°F is usually chosen as an arbitrary starting point from which the reception of heat is to be reckoned. We shall employ the symbol h to designate the heat required to raise 1 lb of water from 32°F to the temperature t at which steam begins to form. The value of h in thermal units is given, approximately, by the equation

$$h = t - 32$$

More exact values, which take account of the variation in the specific heat of water, will be found in the last column of Table II. During the first stage, sensibly all the heat supplied goes to increase the stock of internal energy which the fluid possesses, the amount of external work which is done by the expansion of the fluid being negligible.

60 The heat taken in during the second stage is what is called the *latent heat of steam*, and is denoted by L . Of it a part is spent

¹ See Fairbairn and Tate, 'On the Density of Steam at Different Temperatures,' Phil Trans vol c 1860

² This is Rankine's formula. Zeuner gives $PV^{1.0345} = \text{constant}$

in doing external work,—namely, P multiplied by the excess of the volume of the steam over the volume of the water,—and the remainder is the difference of internal energy between 1 lb of steam at t and 1 lb of water at t . The volume of 1 lb of water, at such temperatures as are usual in steam engines, is nearly 0.017 cubic feet. We may therefore write the external work (in foot-pounds) done during the production of 1 lb of steam under constant pressure P ,—

$$\text{External work} = P(V - 0.017)$$

61 Adding together the heat taken in during the first and second stages we have a quantity designated by H and called the *total heat* of 1 lb of saturated steam —

$$H = h + L$$

Regnault's values of H are very accurately expressed (in thermal units) by the formula
